Civil Engineering Reference Manual

for the PE Exam

Seventh Edition

Michael R. Lindeburg, PE

Professional Publications, Inc. • Belmont, CA

SAIT - Library

Where do I find solutions for the practice problems in this Reference Manual?

The *Civil Engineering Reference Manual* has 440 practice problems to help you prepare for the Civil PE exam. The answers to these problems—*just* the answers—are provided at the end of each problem. The complete, step-by-step solutions to these problems are presented in a separate book, titled *Practice Problems for the Civil Engineering PE Exam: A Companion to the Civil Engineering Reference Manual*. The reason we separate the solutions from the manual is that some states do not permit examinees to bring collections of solved problems into the exam. With the solutions packaged separately, you can study using the *Reference Manual* and *Practice Problems* books together, and then take just the *Reference Manual* with you to the exam.

Practice Problems for the Civil Engineering PE Exam may be purchased from Professional Publications (800-426-1178 or www.ppi2pass.com) or from your favorite bookstore.

How to Get Online Updates for This Book xi

Codes Referenced in This Manual xiii

Introduction xv

Topic I: Background and Support

Systems of Units 1-1
Engineering Drawing Practice 2-1
Algebra 3-1
Linear Algebra 4-1
Vectors 5-1
Trigonometry 6-1
Analytic Geometry 7-1
Differential Calculus 8-1
Integral Calculus 9-1
Differential Equations 10-1
Probability and Statistical Analysis of Data 11-1
Numerical Analysis 12-1
Energy, Work, and Power 13-1

Topic II: Water Resources

Fluid Properties 14-1
Fluid Statics 15-1
Fluid Flow Parameters 16-1
Fluid Dynamics 17-1
Hydraulic Machines 18-1
Open Channel Flow 19-1
Meteorology, Climatology, and Hydrology 20-1
Groundwater 21-1
Inorganic Chemistry 22-1
Organic Chemistry 23-1
Combustion and Incineration 24-1
Water Supply Quality and Testing 25-1
Water Supply Treatment and Distribution . . . 26-1

Topic III: Environmental

Biochemistry, Biology, and Bacteriology 27-1
Wastewater Quantity and Quality 28-1
Wastewater Treatment: Equipment and Processes 29-1
Activated Sludge and Sludge Processing 30-1
Municipal Solid Waste 31-1
Pollutants in the Environment 32-1
Disposition of Hazardous Materials 33-1
Environmental Remediation 34-1

Topic IV: Geotechnical

Soil Properties and Testing 35-1
Shallow Foundations 36-1
Rigid Retaining Walls 37-1
Piles and Deep Foundations 38-1
Temporary Excavations 39-1
Special Soil Topics 40-1

Topic V: Structural

Determinate Statics 41-1
Properties of Areas 42-1
Material Properties and Testing 43-1
Strength of Materials 44-1
Basic Elements of Design 45-1
Structural Analysis I 46-1
Structural Analysis II 47-1
Properties of Concrete and Reinforcing Steel 48-1
Concrete Proportioning, Mixing, and Placing . . 49-1
Reinforced Concrete: Beams 50-1
Reinforced Concrete: Slabs 51-1
Reinforced Concrete: Short Columns 52-1
Reinforced Concrete: Long Columns 53-1
Reinforced Concrete: Walls and Retaining Walls 54-1
Reinforced Concrete: Footings 55-1
Pretensioned Concrete 56-1
Composite Concrete Members 57-1
Structural Steel: Introduction 58-1
Structural Steel: Beams 59-1
Structural Steel: Tension Members 60-1
Structural Steel: Compression Members 61-1
Structural Steel: Beam-Columns 62-1
Structural Steel: Plate Girders 63-1
Structural Steel: Composite Steel Members . . . 64-1
Structural Steel: Connectors 65-1
Structural Steel: Welding 66-1
Structural Steel: Introduction to LRFD 67-1
Properties of Masonry 68-1
Masonry Walls 69-1
Masonry Columns 70-1

Topic VI: Transportation

Properties of Solid Bodies 71-1
Kinematics 72-1
Kinetics 73-1
Roads and Highways: Capacity Analysis 74-1

Vehicle Dynamics and Accident Analysis 75-1
Flexible Pavement Design 76-1
Rigid Pavement Design 77-1
Plane Surveying 78-1
Horizontal, Vertical, Spiral, and Compound Curves 79-1
Construction Earthwork, Staking, and Surveying 80-1

Topic VII: Systems, Management, and Professional

Project Management 81-1
Construction and Job Site Safety 82-1
Electrical Systems and Equipment 83-1
Instrumentation and Measurements 84-1
Engineering Economic Analysis 85-1
Engineering Law 86-1
Engineering Ethics 87-1
Engineering Licensing in the United States . . . 88-1

Topic VIII: Support Material

Appendices A-1
Glossary G-1

Index I-1

Index of Figures and Tables IFT-1

Appendices Table of Contents

1.A Conversion Factors A-3
1.B Common SI Unit Conversion Factors A-5
7.A Mensuration of Two-Dimensional Areas . . A-9
7.B Mensuration of Three-Dimensional Volumes A-11
9.A Abbreviated Table of Indefinite Integrals A-12
10.A Laplace Transforms A-13
11.A Areas Under the Standard Normal Curve A-14
14.A Properties of Water at Atmospheric Pressure (English Units) A-15
14.B Properties of Water at Atmospheric Pressure (SI Units) A-15
14.C Viscosity of Water in Other Units (English Units) A-16
14.D Properties of Air at Atmospheric Pressure (English Units) A-16
14.E Properties of Air at Atmospheric Pressure (SI Units) A-16
16.A Area, Wetted Perimeter, and Hydraulic Radius of Partially Filled Circular Pipes A-17
16.B Dimensions of Welded and Seamless Steel Pipe (English Units) A-18
16.C Dimensions of Welded and Seamless Steel Pipe (SI Units) A-21
16.D Dimensions of Small Diameter PVC Pipe (English Units) A-22
16.E Dimensions of Large Diameter PVC Sewer and Water Pipe (English Units) A-23
16.F Dimensions and Weights of Concrete Sewer Pipe (English Units) A-24
16.G Dimensions of Cast Iron Pipe (English Units) A-25
16.H Standard ANSI Piping Symbols A-26
17.A Specific Roughness and Hazen-Williams Constants for Various Water Pipe Materials A-27
17.B Darcy Friction Factors A-28
17.C Flow of Water Through Schedule-40 Steel Pipe A-32
17.D Equivalent Length of Straight Pipe for Various (Generic) Fittings A-33
17.E Hazen-Williams Nomograph A-34
17.F Corrugated Metal Pipe A-35
18.A International Standard Atmosphere A-36
19.A Manning's Roughness Coefficient, n . . . A-37
19.B Manning Equation Nomograph A-38
19.C Circular Channel Ratios A-39
19.D Critical Depths in Circular Channels . . . A-40
20.A Rational Method Runoff C-Coefficients . . A-41
20.B Random Numbers A-42
22.A Atomic Numbers and Weights of Elements A-43
22.B Periodic Table of the Elements A-44
22.C Water Chemisty $CaCO_3$ Equivalents . . . A-45
22.D Saturation Values of Dissolved Oxygen in Water A-47
22.E Names and Formulas of Important Chemicals A-48
24.A Heats of Combustion for Common Compounds A-49
24.B Approximate Properties of Selected Gases A-50
26.A Properties of Chemicals Used in Water Treatment A-51
29.A Selected *Ten States' Standards* A-52
37.A Active Components for Retaining Walls (Straight Slope Backfill) A-54
37.B Active Components for Retaining Walls (Broken Slope Backfill) A-55
40.A Boussinesq Stress Contour Chart (Infinitely Long and Square Footings) A-56
40.B Boussinesq Stress Contour Chart (Uniformly Loaded Circular Footings) A-57
42.A Centroids and Area Moments of Inertia for Basic Shapes A-58
43.A Typical Properties of Structural Steel, Aluminum, and Magnesium A-59
43.B Typical Mechanical Properties of Representative Metals A-60
44.A Elastic Beam Deflection Equations A-63
45.A Properties of Weld Groups Treated as Lines A-66
47.A Elastic Fixed-End Moments A-67
47.B Indeterminate Beam Formulas A-69
47.C Moment Distribution Worksheet A-74
48.A ASTM Standards for Reinforcing Bars . . A-75
48.B ASTM Standards for Wire Reinforcement A-76
52.A Reinforced Concrete Interaction Diagrams A-77
58.A Common Structual Steels A-80
58.B Properties of Structural Steel at High Temperatures A-81

59.A Moment Gradient Multiplier A-82
66.A Properties of Welds Treated as Lines . . . A-83
69.A Section Properties of Masonry Horizontal Cross Sections A-84
69.B Section Properties of Masonry Vertical Cross Sections A-85
69.C Ungrouted Wall Section Properties A-87
69.D Grouted Wall Section Properties A-88
70.A Column Interaction Diagram (compression controls, $g = 0.4$) A-89
70.B Column Interaction Diagram (compression controls, $g = 0.6$) A-90
70.C Column Interaction Diagram (compression controls, $g = 0.8$) A-91
70.D Column Interaction Diagram (tension controls, $g = 0.4$) A-92
70.E Column Interaction Diagram (tension controls, $g = 0.6$) A-93
70.F Column Interaction Diagram (tension controls, $g = 0.8$) A-94
71.A Mass Moments of Inertia A-95
76.A Axle Load Equivalency Factors for Flexible Pavements (Single Axles and p_t of 2.5) A-96
76.B Axle Load Equivalency Factors for Flexible Pavements (Tandem Axles and p_t of 2.5) A-97
76.C Axle Load Equivalency Factors for Flexible Pavements (Triple Axles and p_t of 2.5) A-98
77.A Axle Load Equivalency Factors for Rigid Pavements (Single Axles and p_t of 2.5) A-99
77.B Axle Load Equivalency Factors for Rigid Pavements (Double Axles and p_t of 2.5) A-100
77.C Axle Load Equivalency Factors for Rigid Pavements (Triple Axles and p_t of 2.5) A-101
78.A Oblique Triangle Equations A-102
83.A Polyphase Motor Classifications and Characteristics A-103
83.B DC and Single-Phase Motor Classifications and Characteristics . . . A-104
84.A Thermoelectric Constants for Thermocouples A-105
85.A Standard Cash Flow Factors A-106
85.B Economic Analysis Factor Tables A-107

Preface to the Seventh Edition

It has been approximately ten years since the last major reorganization of this book, and approximately twenty years since its first edition. When the book has been reprinted each year, I made many minor changes and improvements. However, until this edition, the basic content and structure have remained unchanged.

During the time since I wrote the first edition, I have authored more than twenty books, taught over a thousand civil engineers in classroom courses, read hundreds of multidisciplinary engineering books and magazines, and reviewed thousands of questionnaires from over fifty mail surveys conducted to determine what civil engineers want and need. I have also responded to far too many letters and e-mails from readers telling me how I could have done a better job of presenting the material in my books.

As the owner of this seventh edition of the *Civil Engineering Reference Manual*, you are the beneficiary of all of this.

This new edition is a broad review of civil engineering design and analysis principles, as well as a compendium of data to support those principles. In choosing subjects and data, I was greatly influenced by five sources of information. From the most important to the least, these were: (1) unsolicited and survey comments received from literally thousands of civil engineers who have purchased previous editions of this book; (2) task analyses of the civil engineering profession published by the National Council Examiners for Engineering and Surveying; (3) civil engineering curricula at leading colleges and universities; (4) current literature in the field of civil engineering and construction; and (5) information from the Professional Publications, Inc. (PPI), website (www.ppi2pass.com) and sci.engr.civil newsgroup postings.

Because of its emphasis on undergraduate engineering subjects (the only prerequisite course of study expected of state licensing examinees), this book is an efficient method of preparing for the national Professional Engineering (PE) examination in Civil Engineering. Tens of thousands of engineers have used the previous six editions to do just that.

This book will appeal to more than just PE licensing candidates, however. The intended audience for this book includes civil engineering majors needing a general, all-inclusive reference book covering their course of study, as well as practicing engineers seeking a convenient collection of methods and data covering familiar but perhaps faintly remembered subjects. The intent of this book is to provide you with a resource for your daily work long after you have taken an exam.

An important requirement for passing the PE examination is adequate exposure to the broad range of question types typically found on the examination. While I have not included any actual examination problems, this book contains numerous practice problems in all PE subject areas. Using original problems maintains the validity of the examination process.

I know from firsthand experience that the easiest type of engineering book to write is a collection of solved problems. And I admit that I have authored my share of problem collections. However, the effort required to compile typical engineering problems pales in comparison to the effort required to present the engineering knowledge needed to solve them.

I have added approximately 170 new problems to this edition, increasing the total count to 440, but I am still not content with the number of problems in each chapter. Some of the chapters could use even more! I guess that means there will be another edition someday. In the meantime, if you want more practice with problems that are representative of the level of difficulty of PE exam problems, I suggest you obtain either *Civil Engineering Sample Examination* (which contains twenty problems) or *101 Solved Civil Engineering Problems*, both authored by me and published by PPI.

I have organized this book such that each topic is presented in its own standalone section. In most cases, each successive chapter builds on previous chapters, and each successive section builds on the information in previous sections. As much as possible, the chapters use common nomenclature.

There are many, many differences between this edition and the previous edition. In fact, this edition is essentially a brand new book. Here are some of the major differences.

- The most current references have been used for building codes and traffic/transportation subjects.
- Many new subjects have been added, and coverage of existing subjects has been greatly expanded. Many new tables of data have been added, and existing tables have been updated. The original 22 chapters of the old edition have been expanded into 88 chapters covering smaller amounts of engineering knowledge.

- Sections within each chapter have been organized in a logical, progressive order.
- In most cases, SI units, equations, data, and examples are presented in parallel with their customary U.S. counterparts.
- The nomenclature used in the various source documents has been adopted.
- Many changes have been made to the practice problems. Multiple-choice problems have been added. Careful attention has been given to the scenario statement, with an eye toward what you are expected to know or assume. Many items in previous editions that were left as assumptions or that required research are now explicitly stated.
- The end-of-chapter practice problems that most closely parallel exam problems in level of difficulty are identified with the phrase "Time limit—one hour."
- Numerical answers are given to the practice problems. Thus, this book can be used independently of the accompanying *Practice Problems* solutions manual.
- All appendices have been relocated to the end of the book.
- The index has been expanded, and most entries have been entered in several different ways.
- Sources of figures and tables have been rigorously cited, even when the original sources are in the public domain.

The presentation has been enhanced with a better page design, increased use of figures, and modern typographic techniques. Virtually all of the illustrations were drawn on the computer. Other innovations in typesetting and illustrating have been used to produce this book, but the details are pretty boring unless you are a publisher.

With respect to modern civil engineering practice and current emphasis in academia, I have omitted some obsolete material that was included in the previous edition. There is a decreased emphasis on lengthy manual structural analysis procedures such as moment distribution and conjugate beam methods. Material on solar and astronomical observations has been omitted. Several alternate procedures have been replaced by the methodologies that are more dominant in the industry. The management psychology chapter has been eliminated completely.

Then again, I have included some new material that may seem as equally obtuse as the material I have removed. However, there is a logical reason for everything in this book. Trust me.

I admit that the scope of this book slightly exceeds that of the PE exam, and that some of the end-of-chapter practice problems are marginally more difficult than typical exam problems. (Many are easier, as well.) As I wrote the book, I kept chanting, "Engineers should know something about everything." I included the subjects that I thought you should know something about. If you use this book as a PE exam reference, you will end up being somewhat overprepared for the exam.

The choice of subjects and data to be included in this book, though greatly influenced by thousands of engineers, was ultimately mine, as was the choice of degree and depth of coverage of these subjects. After all these years, I think that I have a pretty good feel for the academic needs of a civil engineer. But, time marches on. You can help me keep this book relevant by doing what thousands of engineers have already done: Stay in touch. The next edition will be the result of your input.

Thanks!

Michael R. Lindeburg, PE
mlindeburg@ppi2pass.com

Acknowledgments for the Seventh Edition

Maybe it is my imagination. Or perhaps I am just getting numb. But producing this book seemed to go more quickly and smoothly than did previous books I have written. Still, producing this book was far from a one-person show.

Two individuals had significant effects on this book in the months prior to publication. Tamer Hadi, a multidisciplinary bioengineering major at the University of California (Berkeley, CA), and Dina Hadi, an equally multidisciplinary mechanical engineering major at Santa Clara University (Santa Clara, CA), spent the equivalent of almost a year doing the final technical edit and proofing. After PPI's in-house proofreaders and editors had polished the pages, Dina and Tamer were the first engineers to see the galley proofs, often beating me by several months. They meticulously checked numbering, calculations, references, and units using a list of details that only another engineer (like me) could have devised. The quality of this book is a testimony to their dedication.

The Professional Publications team that contributed to this book is substantial in number and talent. Dean Suzuki, Chief Operating Officer, took over all of my management workload to give me the writing time I needed. First Aline Magee, and then later, Jessica Holden, as Production Department Managers, monitored the editing, typesetting, illustrating, and printing schedules. After her promotion to Acquisitions Editor, Aline subsequently proofread substantial amounts of this book, as did former Acquisitions Editor Peggy Yoon. Both Peggy and Aline worked tirelessly to obtain all of the permissions (almost a hundred) that were needed in order to use figures and data from other publishers' books. Barbara Kendrick, Marketing Department Manager, fed me customers' ideas, suggestions, and demands. She also kept me informed of the needs of engineering review course instructors.

Jessica Holden was also the copy editor for this book. She was the first PPI employee to see my raw manuscript, and she did a bang-up job. Being a great copy editor requires much, much more than just copy editing. A copy editor gives a book personality. Her personality. A copy editor gives a book its style and consistency. To be a great copy editor, you have to be in tune with the subject material. Jessica has done all of that, and her efforts have brought my books to a new level of professionalism.

Yvonne Sartain rendered most of my illustrations, assisted by Colleen Cameron. As previous editions of this book had ink-drawn illustrations, Yvonne had to redo every old illustration electronically for this new edition. When you count the number of illustrations in this book and then multiply that number by the number of hours it took to produce each illustration to PPI's rigorous style standards, you will come up with a number that even a savant would have trouble manipulating.

Kate Hayes typeset the entire book. She voted with her hands and elected you the winner of a beautifully laid-out book. She always had a smile for me when I visited with her. What is really humbling is the number of characters she keyboarded. In order to achieve industry-standard typographical quality, PPI uses (and always has used) professional typographic software, not WYSIWYG word processing software. There is tremendous electronic "overhead" with technical typesetting of this nature. Every Greek letter and symbol I wrote required her to do more than I care to think about.

These days, there are very few graduates who can properly check spelling, punctuation, and grammar. The quality of our educational system makes finding first-rate proofreaders a challenge. But PPI has cut no corners in this area, either. Along with Aline, first Peggy, then later Vanessa Franco, and finally David Nielsen proofed the galleys and page proofs, and they did so more times than I did. (And, more times than I even know about, because I never saw all of the initial galleys.) After trying to read my mind to figure out what I really wanted "it" to look like, they had to remember how "it" was done in previous chapters, and then reconcile the copy-edited manuscript against what was typeset. Proofreading is a very nonlinear, intuitive process. To be a great proofreader, you have to do more than compare two things side by side. You have to remember and think.

This production team is an incredibly competent, dedicated, driven, talented, and forgiving group. I am very fortunate to have had these people work on this book with me.

I was able to write this book in slightly more than two years, but I did it all with mirrors. I got wise after it took five years to write the 10th edition of my *Mechanical Engineering Reference Manual*. That is why I enlisted significant assistance for a number of chapters. For some of the chapters, I asked experts from industry and academia to review the previous edition's chapters, to update and reorganize them where required,

and to write several new original problems. These experts incorporated new topics into the chapter according to their own experience and lists of additions that I provided. When their chapters were submitted to me, I checked and edited every sentence, equation, figure, and table. About one-third of this new edition was produced in this manner.

The following technical experts were invaluable in helping me prepare this edition in a timely manner.

- Dionisio (Dennis) Bernal, PhD, Northeastern University, Department of Civil Engineering: Structural Analysis, Concrete Beams, Slabs, Short Columns, Long Columns, and Footings (Chs. 46, 47, 50–53, 55)
- Maribeth S. Bradfield, PE: Masonry (Chs. 68–70)
- Nirmal K. Das, PhD, PE, Georgia Southern University: Structural Steel, Beams, Tension Members, Columns, Beam-Columns, Plate Girders, Composite Members, Connectors, Welding, and Introduction to LRFD (Chs. 58–67)
- Robert H. Easton, PE: Water Supply Quality and Testing (Ch. 25)
- Harv Hewitt: Water Supply (Chs. 25 and 26)
- Gerald D. Hill, PE: Biochemistry, Wastewater, Sludge Processing, and Waste Storage and Disposal (Chs. 27–31)
- Ann M. Johnson, PE: Traffic Analysis, Accident Analysis, Flexible Pavements, Rigid Pavements, Plane Surveying, and Curves (Chs. 74–79)
- Shahin A. Mansour, PhD, PE, CALTRANS District 6 (Fresno): Concrete, Mixing and Placing, Concrete Walls, Prestressed Concrete, and Composite Concrete Members (Chs. 48, 49, 54, 56, 57)
- Gretchen Rau, MS, PE: Open Channel Flow, Hydrology, Soils Properties, and Foundations (Chs. 19, 20, 35, 36)

Many thanks to my friend John Ruark who gave me the encouragement to get through "Book N." Just as I have to keep reminding the soccer players I coach to "look up before you pass," John had to coach me with "What chapter are you on?" each time I got bogged down. He never lost sight of why I write, and he wouldn't let me forget, either.

This is the first book that one of my children helped me with. Katie, my youngest daughter, organized, edited, and formatted the glossary of terms and the index of figures and tables. When you use these features, please think of the beautiful 15-year-old young lady who gave some of her free time to help make this book more useful to you.

[Jenny] y92 e8e 8 w5q6 wqh3 24858ht r49j 5y3 3q4o83w5 j94h8ht y974w 59 5y3 233 y974w 9r 5y3 h8ty5? 8 yqf3 j6 3oe3w5 eq7ty534 u3hh6 59 5yqhi r94 5yq5. y34 w9dd34 04qd58d3 i305 j6 go99e d84d7oq58ht 2y8o3 y34 dyq5534 qhe u9i3w 59ww3e g35233h 974 529 d9j07534 h99iw 8h j6 9rr8d3 i305 j6 w08485w w9q48ht.

You've heard of "TLC" (tender loving care), right? Well, Elizabeth (my wife) provided liberal amounts of "TRP" (tea, roses, pie) throughout this writing project. Writing this kind of book can get pretty grueling at times. But Elizabeth knew the Rx to keep me going: hot tea at 7:00 A.M., roses at 1:00 P.M., and pumpkin pie at 10:00 P.M. Just the right quantities at just the right times.

This is the last book for which I will have to write something like "Thanks to my wife and children for giving me the time and space to write this book." My eldest daughter is now in college, and my youngest isn't far behind. I may never truly stop writing, but my children won't be part of any next book. I don't even know if I can write without hearing their laughter and questions about chemistry and physics. It certainly won't be as much fun without them.

I realize that my family has probably had its fill of the writer's life. Something about too many vacations in faraway places with a suitcase full of page proofs. Still, someday, I hope my daughters will get to experience the pleasure of holding in their hands a book or article that they have written and had published. Then they will be able to determine for themselves if all this is worth it.

Thanks to you all!

Michael R. Lindeburg, PE

How to Get Online Updates for This Book

I wish I could claim that this book is 100% perfect, but 25 years of publishing have taught me that engineering textbooks seldom are. Even if you had taken only a single engineering course in college, the issue of mistakes in textbooks would certainly be known to you.

In college, you could get by with just writing "ha ha" next to the error in your book before moving on to another topic. But even if everyone in your class announced all the errors found, and even if you sent in your errata to the publisher, you probably never came close to knowing about all of the mistakes in that book.

However, with this kind of a book—one that is critical to your future—you need more support from the publisher. For an exam whose body of knowledge spans everything from Abutments to Zooglea, you should have access to all of the errata that we know about.

So I am inviting you to log on to Professional Publications' internet web site (www.ppi2pass.com) to obtain a current listing of known errata to this book. From the web site home page, choose the "Errata" button. Every significant known update to this book and its solutions manual will be listed as fast as we can say "HTML." Suggestions from readers (such as yourself) will be added as they are received, so check in regularly. Certainly, you should check in just prior to the exam.

PPI and I have gone to great lengths to ensure that we have brought you a high-quality book. Now, we want to provide you with high-quality after-publication support. Please visit us at

www.ppi2pass.com

Codes Referenced in This Manual

This edition of the *Civil Engineering Reference Manual* is based on the following codes, standards, and references. The versions and editions (i.e., dates) that I used were the most current available. However, as with engineering practice itself, the PE examination is not always based on the most currently available codes, as adoptions by state and local agencies often lag issuance by several years.

Professional Publications, Inc. (PPI), lists on its website (www.ppi2pass.com) the dates of the codes, standards, and regulations on which NCEES has announced the current exams are based. You should use this information to decide which versions of these books should be part of your exam preparation.

Policy on Geometric Design of Highways and Streets ("AASHTO Green Book"), English (1990) and metric (1994) units versions. American Association of State Highway and Transportation Officials.

Highway Capacity Manual, Special Report 209, 1997. Transportation Research Board/National Research Council.

AISC/ASD: *Manual of Steel Construction, Allowable Stress Design*, 9th ed., 1989. American Institute of Steel Construction, Inc.

AISC/LRFD: *Manual of Steel Construction, Load and Resistance Factor Design*, 2nd ed., 1994. American Institute of Steel Construction, Inc.

ACI-318: *Building Code Requirements for Structural Concrete*, 1995. American Concrete Institute.

ACI-530: *Building Code Requirements for Masonry Structures*, 1995. American Concrete Institute.

ACI-530.1: *Specifications for Masonry Structures*, 1995. American Concrete Institute.

Introduction

Part 1: How You Can Use This Book

QUICKSTART

If you never read the material at the front of your books anyway, and if you are in a hurry to begin and you only want to read one paragraph, here it is:

> Most chapters in this book are independent. Start with any one and look through it. Decide if you are going to work problems in that subject. Solve all the end-of-chapter practice problems you have time for. Use the index extensively. Don't stop studying until the exam. Start right now! Quickly! Good luck.

However, if you want to begin a thorough review, you will probably try to find out everything there is to know about the PE exam. The rest of this introduction is for you.

IF YOU ARE A PRACTICING ENGINEER

If you are a practicing engineer or an engineering major and have purchased this book as a general reference handbook, it will probably sit in your bookcase until you have a specific need.

However, if you are preparing for the PE examination in civil engineering, a few suggestions may help.

- Become intimately familiar with this book. This means knowing the order of the chapters, the approximate locations of important figures and tables, what appendices are available, and so on.
- Use the subject title tabs along the side of each page. The tab names correspond to the NCEES Breadth and Depth subject categories.
- Know which subjects in this book are not covered in the PE exam. Many chapters in this book are supportive and do not cover exam topics. These chapters provide background for the other chapters.
- Skim through a chapter and familiarize yourself with the subjects before starting the practice problems.
- It isn't necessary to solve every end-of-chapter practice problem. The number of practice problems you solve will depend on how much time you have and how skilled you are in the subject.
- Use the answers to the practice problems to check your work. If your answer doesn't match the given solution, use the separate *Practice Problems for the Civil Engineering PE Exam* to figure out why.
- If you decide to work in customary U.S. (English) units, you will find equations in which the quantity g/g_c appears. For calculations at standard gravity, the numerical value of this fraction is 1.00. Therefore, it is necessary to incorporate this quantity only in problems with a nonstandard gravity, or when you are being meticulous with units.
- To minimize time spent in searching for often-used formulas and data, prepare a one-page summary of all the important formulas and information in each subject area. You can then use these summaries during the examination instead of searching in this book.
- Use the subject index extensively. Every significant term, law, theorem, and concept has been indexed in every conceivable way—backward and forward. If you don't recognize a term used in a problem statement, look for it in the index.
- Some subjects appear in more than one chapter. You should use the index liberally to learn all there is about a particular subject.

IF YOU ARE AN INSTRUCTOR

The first two editions of this book consisted of a series of handouts from one of my PE review courses. These editions were intended to be a compilation of all of the long formulas, illustrations, and tables of data that I did not have time to put on the chalkboard. You can use this edition the same way.

If you are teaching a review course for the PE examination without the benefit of recent, firsthand exam experience, you can use the material in this book as a guide to prepare your lectures. You should emphasize the subjects in each chapter and avoid subjects omitted. You can feel confident that subjects omitted from this book have rarely, if ever, appeared on the PE exam.

It has always been my goal to overprepare my students. For that reason, the practice problems are often more difficult and more varied than actual examination problems. Also, you will appreciate the fact that it is more efficient to cover several procedural steps in one practice problem than to ask simple "one-liners." That is the reason I have limited the number of multiple-choice examples in this book.

There are many practice problems for each major examination subject. All the problems are assigned in my review courses. To do all the problems requires approximately fifteen to twenty hours of preparation per week for approximately fourteen weeks.

"Capacity assignment" is the goal in my review courses. If you assign twenty hours of homework and a student is able to put in only ten hours of preparation that week, that student will have worked to his or her capacity. After the PE examination, that student will honestly say that he or she could not have prepared any more than he or she did in your course.

Homework assignments in my courses are not individually graded. Instead, the students are given in advance the accompanying solutions manual containing solutions to all practice problems. However, each student must turn in a completed set of problems for credit each week. I address special needs or questions written on the assignments by exception.

I have found that a fourteen-week format works well for a PE review course. It's a little rushed, but the course is over before everyone gets bored with my jokes. Each week, there is a three-hour lecture with a short break. The following table outlines a basic course format that has worked well for me. If you can, adding more course time will be appreciated by the students. However, I don't think you can cover the full breadth of material in much less time or in fewer weeks.

Typical PE Review Course Format

meeting	subject covered	chapters
1	Introduction to the Exam, Engineering Economics	88, 85
2	Fluids, Conduit Flow, and Pumps	14–18
3	Open Channel Flow	19
4	Hydrology	20–21
5	Water Supply	25, 26
6	Wastewater	28–30
7	Pollution and the Environment	31–34
8	Soils, Foundations, and Settlement	35, 36, 40
9	Retaining Walls and Deep Foundations	37–39
10	Surveying	78
11	Highway Curves	79
12	Traffic and Accident Analysis	74, 75
13	Mixing Concrete and Concrete Beams	48–50
14	Steel Beams and Columns	59, 61, 62

I have tried to sequence the lectures in a logical, progressive manner, keeping an eye on "playing the high-probability subjects." I cover the subjects that everyone can learn (e.g., fluids and soils) early in the course. I leave the subjects that only daily practitioners should attempt (e.g., concrete, steel, and highway capacity) to the end.

Lecture coverage of some examination subjects is necessarily brief. Other subjects are not covered at all. These omissions are intentional; they are not the result of scheduling omissions. Why? First, time is not on our side in a review course. Second, some subjects rarely contribute to the examination or are not exam topics at all. Third, some subjects are not well received by the students. For example, I have found that very few people try to become proficient in bridges, timber, and masonry if they don't already work in those areas. Most nonstructural civil engineers stick with the nonstructural basics: fluids, soils, surveying, water supply, and wastewater. Most structural engineers stick with structural subjects. Unless you have six months to teach your PE review, your students' time is better spent covering other subjects.

All the skipped chapters and their end-of-chapter practice problems are assigned as floating assignments to make up in the students' "free time."

I strongly believe in exposing my students to a realistic sample examination, but I no longer administer an in-class mock exam. Since the review course usually ends only a few days before the real PE examination, I hesitate to make students sit for several hours in the late evening to take a "final exam." Rather, I distribute and assign a take-home sample examination at the first meeting of the review course.

If the practice test is to be used as an indication of preparedness, caution your students not to even look at the sample exam prior to taking it. Looking at the sample examination or otherwise using it to direct their review will produce unwarranted specialization in subjects contained in the sample examination.

There are many ways to organize a PE review course depending on your available time, budget, intended audience, facilities, and enthusiasm. However, all good course formats have the same result: the students struggle with the workload during the course, and then they breeze through the examination after the course.

Part 2: Everything You Ever Wanted to Know About the PE Exam

WHAT IS THE FORMAT OF THE PE EXAM?

The NCEES professional engineering examination in civil engineering consists of two four-hour sessions separated by a one-hour lunch period. The four-hour

morning session contains twelve problems in a free-response (essay) format, while the four-hour afternoon session contains twelve problems in a multiple-choice format. You must work four problems in each session to receive full credit. There are no required problems.

For each session, you will be given an exam booklet that contains problems only for civil engineers.

WHAT EXAM FORMAT CHANGES MIGHT APPEAR IN THE FUTURE?

Though the basic exam subjects have remained essentially unchanged for decades, the NCEES exam structure has changed numerous times. Discussed, debated, and planned changes include (1) a 100% multiple-choice format, and (2) a breadth-depth format. In a breadth-depth format, all examinees would work the same morning "breadth" problems. In the afternoon, examinees would be able to select from a number of "depth" exams containing a majority of problems from their areas of specialization.

This book is completely consistent with and has anticipated the breadth-and-depth format, as well as the shift to 100% multiple-choice format.

Other changes to the examination, including a "no-choice" format (i.e., having to work eight problems out of eight problems) and offering a computerized exam have been discussed but are very unlikely to be implemented.

Effective dates of planned changes to the exam format are announced on the PPI website (www.ppi2pass.com).

WHAT SUBJECTS ARE ON THE PE EXAM?

NCEES has published a detailed breakdown of subjects on the examination. This breakdown has changed semantically several times in the past, but the nature of the problems has not shifted dramatically. A few changes have been made (e.g., the addition of more complex structural and wastewater subjects and the deletion of engineering economics), but essentially, the "bread-and-butter" types of problems have not changed.

Irrespective of the published examination structure, the exact number of problems that will appear in each subject area cannot be predicted reliably. There is no guarantee that any single subject will occur in any quantity. One reason for this is that some of the problems span several disciplines. You might consider a pump selection problem to come from the subject of fluids, while someone else might categorize it as engineering economy.

Long ago, the regular NCEES PE exam in civil engineering contained only twenty problems, and there were separate exams for sanitary and structural specialists. Eventually, NCEES folded the two specialty exams into the regular civil PE exam by adding four fairly complex problems—two from each of the specialty exams. This is when "esoteric" subjects (e.g., seismic design, masonry, bridges, timber, and complex wastewater chemistry) began appearing regularly on the exam. It is helpful to consider some problems on the current PE exam as being intended for these specialists since these problems are beyond the abilities of most generalists. However, there are still twenty "normal" problems that you should be able to adequately prepare for.

Table 1 is the official NCEES listing of exam subjects. At first glance, the listing appears formidable. However, some of the exam subcategories (e.g., airport terminals, wharfs, bulk cargo terminals, estuaries, and tunneling) are quite general and have never constituted a significant portion of the exam.

WHAT IS THE TYPICAL PROBLEM FORMAT?

Problems in both the morning and afternoon sessions start out with a statement of the "Situation." The situation describes a scenario you might encounter as a professional engineer. All required data should appear in the situation statement.

The subsequent "Requirements" statement lists all of the responses that are needed to obtain full credit on the exam. These requirements are satisfied by writing the calculations, procedures, and conclusions in the solutions booklet.

The solutions booklet is essentially a bound book containing sheets of printed graph paper. Each sheet has a place for your personal identification number, the problem number, the page number, and room for the grader's eventual score. All of the work that you want to be graded is to be placed on these pages.

HOW MUCH MATHEMATICS IS NEEDED FOR THE EXAM?

Generally, only simple algebra, trigonometry, and geometry are needed on the PE exam. You will need to use the trigonometric, logarithm, square root, and similar buttons on your calculator. There is no need to use any other method for these functions.

There are no pure mathematics (algebra, geometry, trigonometry, etc.) problems on the exam. However, you will need to apply your knowledge of these subjects to the exam problems.

Except for simple quadratic equations, you will probably not need to find the roots of high-order equations.

There is little or no use of calculus on the exam. Rarely, you may need to take a simple derivative to find a maximum or minimum of some function. Even more rare is the need to integrate to find an average.

There is essentially no need to solve differential equations. Problems involving vibrations, systems, and fluid mixing problems have appeared from time to time. However, these applications can usually be handled without having to solve differential equations.

Table 1 *Subjects on the Civil Engineering PE Exam*[a]

subject	number of problems[b]
1. *Design and Analysis of Traffic Systems*	1
2. *Operations of Traffic Systems* Traffic control systems and devices, network capacity, intersection capacity, interchanges, capacity simulation, and accident reconstruction	1
3. *Design and Analysis of Transportation Facilities*	2
4. *Construction of Transportation Facilities* Roadbeds and highways, including horizontal and vertical curves, highway embankments, pavements, surfaces, subgrades, soils, and drainage; airports, including terminals, aprons, taxiways, runways, and drainage; public transit and railroads, including stations and facilities, horizontal and vertical curves, roadbeds, track configurations, and control systems; waterfront facilities, including passenger terminals, general cargo terminals, bulk cargo terminals, wharfs, docks, and other facilities	1
5. *Design and Analysis of Buildings and Special Structures* Buildings of concrete, steel, timber, masonry, and other materials, as well as arches, cable-supported structures, fixed and guyed towers, waterfront structures, and other special structures of concrete, steel, timber, masonry, light metal, and other materials	2
6. *Design and Analysis of Bridges and Special Structures* Bridges of concrete, steel, timber, and other materials, as well as special structures such as shoring, bracing, and box culverts	2
7. *Design and Analysis of Foundations and Retaining Structures* Footings, piles, retaining walls, dams and spillways of concrete, steel, timber, masonry, and other materials	2
8. *Design and Analysis of Drainage and Flood Control Systems* Drainage systems, pipe and channel systems, seepage, retention, and open and closed flow systems	2
9. *Design and Analysis in Relation to Natural Water Systems* Watersheds, streams, bays, lakes, estuaries, impoundments, beaches, erosion control, and stream and groundwater pollution monitoring and control	1
10. *Design and Analysis of Water Supply Systems* Collection, distribution, storage, wells, treatment processes, and sludge disposal	2
11. *Design and Analysis of Wastewater Treatment Systems*	2
12. *Wastewater Treatment Systems Operations* Collection, flow equalization, storage, treatment processes and plants, self-purification, sludge disposal, disposal controls, energy recovery, and plant location	1
13. *Design and Analysis of Solid/Hazardous Waste Systems* Solid waste systems including collection, storage, treatment, and disposal (incineration, composting, recycling, landfilling), quantity estimates, site and haul economics, and energy recovery and hazardous waste systems, including identification, collection, processing, and disposal	1
14. *Design and Analysis of Geotechnical/Soils Projects*	2
15. *Construction of Geotechnical/Soils Projects* Earth exploration, pavements, deep and shallow foundations, retaining walls, earth dams, embankments, slope stability, and tunneling	1
16. *Construction/Materials Testing* Soils, concrete, metals, timbers, masonry, and other materials	1

[a] As of October 1991. Some problems may require knowledge of engineering economics.
[b] Morning essay problems and afternoon multiple-choice questions, combined. Examinees select and work eight problems.

Basic statistical analysis of observed traffic and surveying data may be necessary. Statistical calculations are generally limited to finding means, medians, standard deviations, variances, and confidence limits. The only population distribution you need to be familiar with is the normal curve. Probability, reliability, hypothesis testing, and statistical quality control are not exam subjects.

The PE exam is concerned with numerical answers, not with proofs or derivations. You will not be asked to prove or derive formulas.

Occasionally, a problem may require an iterative solution method. Generally, there is no need to complete more than two iterations, as by then, you will have shown that you understand the basic concept. You will not need to program your calculator to obtain an "exact" answer. Nor will you generally need to use complex numerical methods.

HOW ABOUT ANY ENGINEERING ECONOMICS PROBLEMS?

For most of the early years of engineering licensing, questions on engineering economics appeared frequently on the examinations. This is no longer the case. However, in its outline of exam subjects, NCEES notes: "Some problems may include economic aspects." What this means is that engineering economics can constitute anything from nothing to a full hour's worth of work on the exam.

If engineering economics is incorporated into other problems, its "disguise" may be totally transparent. For example, you might need to compare the economics of buying and operating two alternative pumping stations whose costs must be calculated from flow rates and heads.

While the degree of engineering economics knowledge may have decreased somewhat, the basic economic concepts (e.g., time value of money, present worth, nonannual compounding, comparison of alternatives, etc.) are still valid test subjects.

WHAT ABOUT ETHICS AND PROFESSIONALISM QUESTIONS?

For many years, the NCEES has discussed adding professionalism and ethics to the PE exam. However, these subjects are not part of the test outline, and there has yet to be a question on them on the exam.

WHAT IS THE FORMAT OF OBJECTIVELY SCORED PROBLEMS?

All problems in the afternoon session are objectively scored. This means that each of the twelve afternoon problems consists of ten multiple-choice questions that are graded by computer. There is no penalty for guessing or wrong answers, but there is also no partial credit for correct methods and assumptions. There are no objectively scored problems in the morning session.

Examinees unanimously report that the multiple-choice afternoon problems are more difficult and time-consuming than the morning essay questions. One of the more disquieting aspects of these problems is that the available answer choices are seldom exact. Answer choices generally have three significant digits. Questions ask, "Which answer choice is closest to the correct value?" or they instruct you to complete the sentence "The value is approximately..." A lot of self-confidence is required to move on to the next question when you don't find an exact match for the answer you calculated, and you have had to split hairs because no available answer choice is really close.

NCEES tries hard to make sure the multiple-choice problems are not greatly interrelated. Most problems are independent or start with new given data. Although a mistake on one of the first ten questions shouldn't cause you to get the next question wrong, considerable time is required to repeat previous calculations with an independent set of given data.

The multiple-choice questions are not necessarily in logical or progressive order. It may be necessary to solve these problems from the "bottom up," determining answers to subsequent questions before the answers to the first few questions are needed.

HOW LONG ARE THE PROBLEMS?

At one time, NCEES specified that the average time required for a registered engineer with "average experience" was 20 minutes per problem. I doubt even a registered engineer could solve exam problems that quickly. However, none of the examinees are registered engineers anyway. So, this time estimate will apply only in the rare situation where you find a problem just like the ones you do every day.

NCEES claims that the average time for a minimally qualified "average examinee" with little or no experience is 45 minutes per problem. This time estimate is more representative of what is experienced by well-prepared examinees. That time can be increased greatly if you haven't prepared or don't know where anything is in your books. It basically takes 45 minutes to work cleanly and solidly through each problem. There isn't much time for flailing around.

IS THE EXAM TRICKY?

The PE exam is not "tricky." The exam does not overtly try to get you to fail. Examinees manage to fail on a regular basis with perfectly straightforward problems. The exam problems are difficult in their own right. NCEES does not need to provide misleading or conflicting statements. However, with the multiple-choice

problems, you might find that commonly made mistakes are represented in the available answer choices. Thus, the alternative answers (known as *distracters*) will be logical.

Problems are generally practical, dealing with common and plausible situations that you might experience in your job. You will not be asked to design a structure for reduced gravity on the moon, to design a mud-brick wall, to analyze the effects of a bomb blast on a structure, or to use bamboo for structural reinforcing.

WHAT MAKES THE PROBLEMS DIFFICULT?

Some problems are difficult because the pertinent theory is not obvious. Many highway capacity analysis problems are of this variety. There is only one acceptable procedure—it is heuristic—and nothing else is acceptable.

Some problems are difficult because the data needed are hard to find. Some data just aren't available unless you happen to have brought the right reference book. Many of the structural problems are of this nature. There is no way to solve most structural steel problems without the *AISC Manual*. Similarly, designing an eccentrically loaded concrete column without published column interaction diagrams is nearly impossible.

Some problems are difficult because they defy the imagination. Three-dimensional structural problems and some surveying curve problems fit this description. If you cannot visualize the problem, you probably cannot solve it.

Some problems are difficult because the computational burden is high and they just take a long time. Pipe networking problems solved with the Hardy Cross method fall into this category.

Some problems are difficult because the terminology is obscure, and you just don't know what the terms mean. This can happen in almost any subject.

DOES THE PE EXAM USE SI UNITS?

The PE exam in civil engineering is written predominantly in customary U.S. units (also known as "English units," "inch-pound units," "Imperial units," and "British units"). Most problems use units of pounds, kips, feet, seconds, gallons, and degrees Fahrenheit. SI units are sometimes used in fluids, water-supply and wastewater, surveying, and traffic/transportation problems. Code-related structural problems remain in customary U.S. units.

The exam does not differentiate between lbf and lbm (pounds-force and pounds-mass) in the problem "Situation" statement. However, a few official solutions that NCEES has published for public review have made the distinction.

WHY DOES NCEES REUSE SOME PROBLEMS?

NCEES reuses some of the more reliable problems from each exam. The percentage of repeat problems isn't high—approximately 25% of the exam. NCEES repeats problems in order to equate the performance of your group of examinees with the performance of an earlier group.

Once in a while, a new problem appears on the exam that very few examinees select. Usually, the reason is that the subject is too obscure or too difficult. Problems in water chemistry, timber, masonry, and project management often fall into this category. Also, there have been cases where a low percentage of the examinees get a passing score because a problem was inadvertently stated in a poor or confusing manner.

NCEES tracks the usage and "success" of each exam problem. Such "rogue" problems are not repeated without modification. This is one of the reasons that historical analysis of oddball problem types shouldn't be used as the basis of your review.

WHAT REFERENCE MATERIAL IS PERMITTED IN THE EXAM?

The PE examination is open-book. Most states do not have any limits on the numbers and types of books you can use. Personal notes in a three-ring binder and other semipermanent covers can usually be used.

The references you bring into the examination room in the morning do not have to be the same as the references you use in the afternoon. However, you cannot share books with other examinees during the exam.

A few states do not permit collections of solved problems such as *Schaum's Outline Series* and solutions manuals to review books. A few states maintain a formal list of banned books.

Strictly speaking, loose paper and scratch pads (including Post-it® notes) are not permitted in the examination room. Certain types of preprinted graphs and logarithmically scaled graph papers (which are almost never needed) should be three-hole punched and brought in a three-ring binder. An exception to this restriction may be made for laminated and oversize charts, graphs, and tables that are commonly needed for particular types of problems. However, there probably aren't any such items for the civil PE exam.

HOW MANY BOOKS SHOULD YOU BRING?

You actually won't use many books in the examination. The trouble is, you don't know in advance which ones you will need. That's the reason many examinees show up with boxes and boxes of books. Without a doubt, there is information you will need that is not in this book. But there is not so much that you need to

bring your company's entire library. The examination is very fast-paced. You will not have time to use books with which you are not thoroughly familiar. The exam doesn't require you to know obscure solution methods or to use difficult-to-find data.

So, it really is unnecessary to bring a large quantity of books with you. The books that are truly useful are identified in this book, and you should be able to decide which of those support the areas in which you intend to work. This book and five to ten other references of your choice should be sufficient for most of the problems you solve.

WHAT THE WELL-HEELED ENGINEER WOULD TAKE TO THE PE EXAM

First of all, you should know that it *is* possible to pass the PE exam using just this book. However, there isn't much margin for error. For example, references aren't needed to do most fluids, hydrology, and soils problems. However, there will be some problems, such as those involving steel design and highway capacity analysis, that you cannot do without the proper references. You would have to be just a little bit lucky to find the right mix of problems.

On the other hand, few examinees are able to accumulate all of the references needed to support the exam's entire body of knowledge. The accumulation process is too expensive and time-consuming and the sources too diverse. Like purchasing an insurance policy, what you end up with will be more a function of your budget than of your needs.

However, if you do have an unlimited budget, then the books listed in Table 2 are those that you should obtain. I have rated these resources according to the following: [***] absolutely necessary if you are going to work problems in this area, [**] useful in less than 50% of the exams, and [*] useful in less than 20% of the exams. I have not listed any resources that would be 100% useless. And there are no books that are 100% necessary for anyone/everybody. If you don't intend to work in a particular subject, you won't even need the "three-star" resources.

Note that building codes may be needed, but only to a very limited extent (e.g., for wind and seismic loadings). Since the PE exam is a national exam, you cannot be required to use one particular building code. So UBC, SBCCI, and BOCA versions of all code-related questions are presented. The code edition (year, version, etc.) tested is a thorny issue, however. The exam can be years behind the most recently adopted code, and many, many years behind the latest codes being published and distributed. (For some parts of the of the exam, the PPI website (www.ppi2pass.com) lists the code editions on which the current exam is based.)

This foregoing listing is only for the major "named" books that have become standard references in the industry. The books listed here are in addition to any resources that you might choose to bring covering soils/geotechnical/foundations, surveying, highway design, hydraulics/fluids, seismic design, steel, concrete, timber, masonry, and unit conversions. Usually, examinees pack these types of books in their boxes "just in case." Most will never be needed in the exam.

WHAT YOU WON'T NEED

Generally, people bring too many things to the examination. One general rule is that you shouldn't bring books that you never looked at during your review. If you didn't need a book while doing the practice problems in this book, you won't need it during the exam.

There are some other things that you won't need.

- Books on basic and introductory subjects: You won't need books that cover trigonometry, geometry, or calculus. You probably won't even need books that cover basic engineering subjects such as statics, mechanics of materials, and so on.
- Books on non-exam subjects: Such subjects as electricity and electronics, materials science, drafting, atomic theory and nuclear engineering, history, the English language, and geography are not part of the exam.
- Books on mathematical analysis, or extensive mathematics tabulations
- Extensive collections of material properties: The exam will not expect you to know the mechanical properties of obscure or exotic alloys. Most mechanical properties are provided as part of the problem statement.
- Local, county, or state-specific building codes
- Obscure books and materials: Books that are in a different language, doctoral theses, and papers presented at technical societies won't be needed on the exam.
- Old textbooks, or obsolete, rare, and ancient books: NCEES exam problem writers are aware of which textbooks are currently in use. Material that is available only in out-of-print publications and old editions won't be used.
- Handbooks in other disciplines: You won't need a mechanical, electrical, or industrial engineering handbook.
- *Handbook of Chemistry and Physics*
- Computer science books: You won't need to bring books covering computer logic, programming, algorithms, program design, or subroutines for BASIC, FORTRAN, C, Pascal, HTML, Java, or any other language.

[*] *Standard Handbook for Civil Engineers*, Frederick S. Merritt, et. al., McGraw-Hill Book Company.

[*] *Standard Methods for the Examination of Water and Wastewater*, a joint publication of the American Public Health Association (APHA), the American Water Works Association (AWWA), and the Water Pollution Control Federation (WPCF).

[a]See Professional Publications' website (www.ppi2pass.com) for most recent edition and date information.

- Crafts- and trades-oriented books: The exam does not expect you to have detailed knowledge of trades or manufacturing operations (e.g., carpentry, plumbing, electrical wiring, roofing, sheetrocking, foundry, metal turning, sheet-metal forming, or designing jigs and fixtures).
- Manufacturer's literature and catalogs: No part of the exam requires you to be familiar with products that are proprietary to any manufacturer.
- Government publications: With the exceptions of the publications listed in this chapter, no government publications are needed in the PE exam.
- Your state's engineering practice laws: The PE exam is a national exam. Nothing unique to your state will appear on it.
- Your state's surveying system: You will not be tested on your state's coordinate system.

WHAT ABOUT CALCULATORS?

It goes without saying that a calculator is needed for the exam. However, it may not be obvious that you should bring a spare calculator with you as well. It is always unfortunate when an examinee is not able to finish because his or her calculator was dropped, was stolen, or stopped working for some unknown reason.

The exam has not been "optimized" for any particular brand or type of calculator. In fact, for most problems, a $15 scientific calculator will produce as satisfactory results as a $200 calculator. There are definite advantages to having built-in statistical functions, graphing, unit-conversions, and root-finding capabilities. However, these advantages are not so great as to give anyone an unfair advantage.

In most states, any calculator may be used as long as it is silent, is non-printing, does not have any significant word-processing functions (i.e., does not have a QWERTY keyboard). In most states, there are no restrictions on using programmable, preprogrammed, or business/financial calculators. Similarly, nomographs and specialty slide rules are permitted (though solutions based on such items won't get you many points).

It is essential that a calculator used for the civil PE examination have the following functions.

- trigonometric functions
- inverse trigonometric functions
- pi
- square root and x^2
- both common and natural logarithms
- y^x and e^x

For maximum speed, your calculator should also have or be programmed for the following functions.

- interpolation
- finding standard deviations and variances
- extracting roots of quadratic equations
- calculating determinants of matrices
- linear regression
- calculating factors for economic analysis problems

You cannot share calculators with other examinees.

Laptops are generally not permitted in the examination. Their use has been discussed, and some states may permit them. However, considering the nature of the exam questions, it is very unlikely that laptops would provide any advantage.

You may not use a walkie-talkie, cellular telephone, interactive pager, or other communications device during the exam.

Be sure to take your calculator with you whenever you leave the examination room for any length of time.

HOW IS THE EXAM GRADED AND SCORED?

The maximum number of points you can earn on the civil engineering PE exam is 80. The minimum number of points for passing (referred to by NCEES as the *cut score*) is almost always 48 points. This means that an average score of 6 points per problem is enough to pass. Poor performance on one problem can be compensated for by good performance on another, as long as a total score of 48 or higher is achieved.

Each essay (free-response) problem in the morning session is worth 10 points. Each problem is graded by a technical expert (which NCEES calls a *subject matter expert*) working against a standardized scoring plan. This method is referred to as the *criterion-referenced grading method*. The scoring plan consists of the specific features, calculations, assumptions, or sequence of steps that NCEES is looking for in the solution. Each feature must be present in your solution in order to get the 2 points associated with it. If one of the scoring plan items is missing or if mathematical errors are made, points will be deducted from the maximum score of 10. (It is possible to make a single minor mathematical error and still receive 8 or 10 points.) In developing the grading plan, particular attention is given to the responses necessary to get 6 points.

Since multiples of 2 points are subtracted when one of the criteria are missing, the only possible scores on essay problems are 10, 8, 6, 4, 2, and 0 points.

As an example of a criterion-graded problem, consider the design of a long circular concrete culvert. In order to receive 10 points, you might have to:

- Consider the effects of friction on the hydraulic head.
- Calculate the flow rate based on the correct hydraulic head.
- Recognize that the flow was entrance-controlled and the culvert does not flow full.
- Calculate the normal depth to within ±10% from the answer key.
- Verify that the normal depth was less than the critical depth.
- Set up all equations correctly, though not necessarily complete the problem or obtain the correct answer.

Getting full credit on an essay problem requires solving it completely and correctly, with no significant mathematical errors in the solution.

Only work that you have entered into the solutions booklet on the right-hand pages will be graded. Nothing that you have written on the left-hand pages or in the exam booklet will be graded.

Each of the objectively scored problems in the afternoon session is also worth 10 points (1 point for each of the 10 multiple-choice questions). Grading is straightforward, since a computer grades your score sheet. You either get the question right or you don't. There is no deduction for incorrect answers, so guessing is encouraged. However, if you mark two or more answers, no credit will be given for the question.

You will receive the results of your examination from your state board (not NCEES) by mail. Allow at least four months for notification. Your score may or may not be revealed to you, depending on your state's procedure. Even when the score is reported to you, it may have been scaled or normalized to 100%.

WHAT IS THE HISTORICAL PASSING RATE?

On the average, the passing rate for first-time examinees seems to hover around 50% or slightly below. The passing rate for repeat examinees is lower—about 40%. The overall passing rate varies considerably from exam to exam. It might be 60% for one exam and then 40% six months later. Because of this variability, and since it's impossible to predict how many of the problems you will consider to be easy, historical passing rates are essentially irrelevant.

CHEATING AND EXAM SUBVERSION

There aren't very many ways to cheat on an open-book test. The proctors are well-trained on the few ways that do exist. It goes without saying that you should not talk to other examinees in the room, nor should you pass notes back and forth. The number of people who are released to use the restroom may be similarly limited to prevent discussions.

NCEES regularly reuses good problems that have appeared on previous exams. Therefore, examination security is a serious issue with NCEES, which goes to great lengths to make sure nobody copies the problems. You may not keep your exam booklet, enter text of problems into your calculator, or copy problems into your own material.

The proctors are concerned about *exam subversion*, which generally means any activity that might invalidate the examination or the examination process. The most common form of exam subversion involves trying to copy exam problems for future use.

Part 3: How To Prepare For and Pass the PE Exam in Civil Engineering

WHAT SHOULD YOU STUDY?

The exam covers many diverse subjects. Strictly speaking, you don't have to study every subject on the exam in order to pass. However, the more subjects you study, the better your chances will be of passing the examination. You should decide early in the preparation process which subjects you are going to study. The strategy you select will depend on your background. Here are the four most common strategies.

- A broad approach has been successful for examinees who have recently completed their academic studies. Their strategy has been to review the fundamentals in a broad range of undergraduate civil engineering subjects. (This means studying all or most of the chapters in this book.) The examination includes enough fundamentals problems to make this strategy worthwhile. This is the best strategy.
- Engineers who have little time to prepare tend to concentrate on the subjects in which they will find the most problems. By studying the list of examination subjects, some have been able to choose those that will give them the highest probability of finding enough problems they can solve. This strategy works as long as the examination "cooperates" and has enough of the types of problems they need. Too often, though, examinees who "pick and choose" subjects to review can't find enough problems to complete the exam.

- Engineers who have been away from classroom work for a long time tend to concentrate on the subjects in which they have had extensive experience and hope that problems in those subjects will be on the exam. This method is seldom successful.
- Some engineers plan on modeling their solutions from similar problems they have found in textbooks, collections of solved problems, and old exams. These engineers often spend a lot of time indexing the example and sample problem types in all of their books. This is not a legitimate preparation method, and it is almost never successful.

DO YOU NEED A CLASSROOM REVIEW COURSE?

Most first-time PE examinees take a review course of some form. Classroom, audio, video, correspondence, and internet courses are available. Classroom review courses are useful for a number of reasons. Courses provide several significant advantages over self-directed study, some of which may apply to you.

(1) A course structures and paces your review. It keeps you going forward without getting bogged down in one subject.

(2) A course focuses you on a limited amount of material. Without a course, you may not know what subjects to study.

(3) A course provides you with the problems you need to solve. You won't have to spend time looking for problems to solve.

(4) The course "spoon-feeds" you the material. You may not need to read the book!

(5) The course instructor can answer your questions when you get stuck.

You probably already know if any of these advantages apply to you. A review course will be less valuable if you are thorough, self-motivated, and highly disciplined.

HOW LONG SHOULD YOU STUDY?

We've all heard stories of the person who didn't crack a book until the week before the exam and still passed it with flying colors. Yes, these people really exist. But I'm not one of them, and you probably aren't either. In fact, after having taught thousands of engineers in my own classes, I'm convinced that these people are as rare as the ones who have taken the exam five times and still can't pass it.

A thorough review takes approximately 300 hours. Most of this time is spent solving problems. Some of it may be spent in class; some is spent at home solving problems. Some examinees spread this time over a year; others cram it all into two months. Most classroom review courses last for three to four months. When you start studying will depend on how much time you can spend per week.

SHOULD YOU LOOK FOR OLD EXAMS?

The traditional approach for preparing for standardized tests includes working sample tests. However, NCEES does not release old tests or problems after they are used. Therefore, there are no official problems or tests available from legitimate sources. NCEES has published a booklet of 24 sample problems and solutions to illustrate the format of the exam. However, these problems have been assembled from various previous exams, and the publication is not a true "old exam."

ADDITIONAL REVIEW MATERIAL

In addition to this book and its accompanying solutions manual, PPI can provide you with the following references and study aids.

- *Civil Engineering Sample Examination* (24 solved problems in representative exam format)
- *101 Solved Civil Engineering Problems* (101 solved free-response problems in the most popular exam subjects)
- *Quick Reference for the Civil Engineering PE Exam* (a compilation of some of the most important formulas needed in the exam, arranged by exam subject)
- *Engineering Unit Conversions* (a compilation of thousands of commonly needed conversions)

DO YOU NEED A SCHEDULE?

It is important that you develop and adhere to a review outline and schedule. Once you have decided which subjects you are going to study, you can allocate the available time to those subjects in a manner that makes sense to you. If you are not taking a classroom review course (where the order of preparation is determined by the lectures), you should prepare your own Outline of Subjects for Self-Study to schedule your preparation.

HOW YOU CAN MAKE YOUR REVIEW REALISTIC

In the exam, you must be able to quickly recall solution procedures, formulas, and important data. You must remain sharp for eight hours or more. When you played a sport back in school, your coach probably tried to put you in game-related situations. Preparing for the PE exam isn't much different from preparing for a big game. Some part of your preparation should be realistic and representative of the examination environment.

There are several things that you can do to make your review more representative. For example, if you gather most of your review resources (i.e., books) in advance and try to use them exclusively during your review, you will become more familiar with them. (Of course, you can add to or change your references if you find inadequacies.)

Another good suggestion is to work all of your homework problems on gridded paper. During the actual exam, your answers to the essay problems will be written on gridded paper (lines drawn six to the inch). Some examinees find this gridded paper difficult to get used to, so adjusting to it before the exam can be helpful.

Learning to use your time wisely is one of the most important things you can do during your review. You will undoubtedly encounter review problems that end up taking much longer than you expected. In some instances, you will cause your own delays by spending too much time looking through books for things you need (or, just by looking for the books themselves!). Other times, the problems will just entail too much work. Learn to recognize these situations so that you can make intelligent decisions about such problems during the exam.

Some of the end-of-chapter problems in this book are marked "*Time limit: one hour.*" These problems are representative of the types of questions, level of difficulty, and duration that you will encounter on the actual exam. Watch the clock while you are solving these problems. Although the spread in problem complexities and lengths is fairly wide, you should be able to complete most of these problems in less than an hour.

WHAT TO DO A FEW DAYS BEFORE THE EXAM

There are a few things that you should do a week or so before the examination. Make arrangements for child care and transportation. Since the examination does not always start or end at the designated time, make sure such arrangements are flexible.

If it is convenient, visit the exam site in order to find the building, parking areas, examination room, and restrooms.

If your spare calculator is not the same as your primary calculator, spend a few minutes familiarizing yourself with its functioning.

Take the battery cover off your calculator and check to make sure you are bringing the correct-size replacement batteries. Put the cover back on and secure it with a piece of masking tape. Write your name on the tape to identify your calculator.

Second in importance to your scholastic preparation is the preparation of your two examination kits. The first kit consists of a bag or box (plastic milk crates work well, but handled suitcases with wheels are better) containing items to be brought with you into the examination room.

- [ ] letter admitting you to the examination
- [ ] photographic identification (e.g., driver's license)
- [ ] this book
- [ ] other textbooks and reference books
- [ ] regular dictionary
- [ ] scientific/engineering dictionary
- [ ] review course notes in a three-ring binder
- [ ] cardboard boxes or plastic milk crates to use as a bookcase
- [ ] primary calculator
- [ ] spare calculator
- [ ] instruction booklets for your calculators
- [ ] extra calculator batteries
- [ ] mechanical pencils or several sharpened pencils
- [ ] erasers
- [ ] straight-edge and rulers
- [ ] compass
- [ ] protractor
- [ ] scissors
- [ ] stapler
- [ ] transparent tape
- [ ] graph paper (a few sheets of each in a three-ring binder)
  - [ ] 10 squares to the inch × 10 squares to the inch
  - [ ] semi-log (3 cycles × 10 squares to the inch)
  - [ ] log-log (3 cycles × 3 cycles)
- [ ] magnifying glass
- [ ] unobtrusive snacks or candies (keep in your pocket)
- [ ] travel pack of Kleenex™ (keep in your pocket)
- [ ] handkerchief
- [ ] headache remedy
- [ ] personal medication
- [ ] $3.00 in miscellaneous change
- [ ] light, comfortable sweater
- [ ] loose shoes or slippers
- [ ] cushion for your chair
- [ ] earplugs
- [ ] wristwatch with alarm

[ ] wire coat hanger

[ ] small screwdriver (to repair eyeglasses and replace calculator batteries)

[ ] extra set of car keys

The second kit consists of the following items that should be left in a separate bag or box in your car in case they are needed.

[ ] copy of your application

[ ] proof of delivery

[ ] light lunch

[ ] beverage in thermos and cans

[ ] sunglasses

[ ] extra pair of prescription glasses

[ ] raincoat, boots, gloves, hat, and umbrella

[ ] street map of the examination area

[ ] note to the parking patrol for your windshield

[ ] battery-powered desk lamp

[ ] your cellular phone

The following items cannot be used during the examination and should be left at home.

[ ] fountain pens

[ ] radio or tape player

[ ] battery charger

[ ] extension cords

[ ] scratch paper

[ ] note pads

Practice setting up your examination work environment. Carry your boxes to the kitchen table. Arrange your "bookcases" and supplies. Decide what stays on the floor in boxes and what gets an "honored position" on the tabletop.

WHAT TO DO THE DAY BEFORE THE EXAM

Take the day before the examination off from work to relax. Do not cram the last night. A good night's sleep is the best way to start the examination. If you live a considerable distance from the examination site, consider getting a hotel room in which to spend the night.

Make sure your exam kits are packed and ready to go.

Turn off the quarterly and hourly alerts on your wristwatch. Leave your pager at home. If you must bring it, change it to silent mode.

Calculate your wake-up time and set the alarms on two bedroom clocks.

Select and lay out your clothing items.

Select and lay out your breakfast items.

Make sure you have gas in your car and money in your wallet.

WHAT TO DO THE DAY OF THE EXAM

Bring or buy a morning newspaper.

Arrive at least 30 minutes before the examination starts. This will allow time for finding a convenient parking place, bringing your materials to the examination room, making room and seating changes, and calming down. Be prepared, though, to find that the examination room is not open or ready at the designated time.

Once you have arranged the materials around you on your table, take out your morning newspaper and look cool. (Only nervous people work crossword puzzles.)

WHAT TO DO IN THE EXAM

All of the procedures typically associated with timed, proctored, computer-graded assessment tests will be in effect when you take the PE examination.

The proctors will distribute the examination booklets and answer sheets (or blank solution booklets) if they are not already on your table. However, you should not open the booklets until instructed to do so. You may read the information on the front and back covers, and you should write your name in the appropriate blank spaces.

Listen carefully to everything the proctors say. Do not ask your proctors any engineering questions. Even if they are knowledgeable in engineering, they will not be permitted to answer your questions.

For the morning essay (free-response) problems, record your examinee number on every page in the solutions booklet. Also, you must list the problem numbers you want graded on the outside of your solutions booklet. You may work more than four problems, but only the four that you list on the front cover will be graded.

Answers to the afternoon multiple-choice problems are recorded on an answer sheet contained in the test booklet. The proctors will guide you through the process of putting your name and other biographical information on this sheet when the time comes, which will take approximately 15 minutes. You will be given the full four hours to work problems. Time to initialize the answer sheet is not part of your four hours.

The common suggestions to "use #2 pencils, completely fill the bubbles, and erase completely" apply here. Actually, mechanical pencils with HB lead can also be used. Use of ballpoint pens and felt-tip markers is discouraged for several reasons.

If you finish the exam early and there is still more than 30 minutes remaining, you will be permitted to leave the room. If you finish less than 30 minutes before the

end of the exam, you may be required to remain until the end, in order to be considerate of the people who are still working.

When you leave, you must return your exam booklet. You may not keep the exam booklet for later review.

HOW TO CHOOSE YOUR PROBLEMS

Read through all of the problems before starting to work. You shouldn't attempt the very first problem you find that you think you can solve. In order to save you from rereading and reevaluating each of the problems later in the session, you should classify each problem at the beginning of the session. The following categories have been used by many successful examinees.

- Problems you can do easily
- Problems you can do with effort
- Problems on which you think you might get partial credit
- Problems you cannot do

All of the problems on the exam are worth the same number of points, so do the problems in order of increasing difficulty. There is nothing to be gained by attempting the difficult or long problems, even if they are in your area of expertise, if easier or shorter problems are available. There is no penalty for selecting all of the problems in a particular subject (e.g., all of the water supply and wastewater problems).

HOW TO SOLVE MULTIPLE-CHOICE PROBLEMS

When you begin the multiple-choice afternoon portion, observe the following suggestions:

- Use only pencil.
- Do not spend more than one hour per problem. If you have not finished a problem in that amount of time, make a note of it and move on.
- Set your wristwatch alarm for five minutes before the end of each four-hour multiple-choice session and use that remaining time to guess at all of the remaining unsolved multiple-choice problems. You will be successful with about 25% of your guesses, and these points will more than make up for the few points that you might earn by working during the last five minutes.
- Make a mental note about any problem for which you cannot find a correct response, that appears to have two correct responses, or that you believe has some technical flaw. Errors in the exam are rare, but they do occur. Such errors are almost always discovered during the scoring process and discounted from the examination, so it is not necessary to tell your proctor, but be sure to mark the one best answer before moving on.
- Make sure all of your responses on the answer sheet are dark and completely fill the bubbles.

HOW TO SOLVE THE ESSAY PROBLEMS

Follow these guidelines when solving the morning essay (free response) problems.

- Use only pencil.
- Be neat. Print all text.
- Do not rewrite the problem statement or redraw any of the figures. That only takes time and will not get you any more points.
- List all of your assumptions (e.g., axial loading, zero friction, turbulent flow).
- Draw a box around each completed answer so the grader will know where to find it.
- Label each answer with a symbol (e.g., "$F = 5$ lbf").
- List the units for each answer.
- Write on one side (the right side) of the page only. The left side is to be used as scratch paper.
- Use one page per problem solved. Don't record more than one problem's solution per page.
- Go through all of the calculations a second time and check for mathematical errors, or solve the problem by an alternate method.

SHOULD YOU CITE YOUR SOURCES?

Solving problems on the PE exam is more like drowning in the ocean than doing a good butterfly stroke the length of the pool. Generally, it will not be necessary to rigorously list the sources of any of your solution methods or data. The technical experts grading your problem will be familiar with all typical variations in procedures used to correctly solve the problems they are grading.

It is certainly not necessary to cite your sources for common information such as economic analysis factors, dimensions of steel pipe, fluid properties, and standard formulas that any engineer should recognize. However, when you use an obscure solution method (e.g., something your own company has developed) or data that even you had a hard time finding, you might want to list the source. This will lend credibility to something that might otherwise seem like hocus-pocus to the grader. The best strategy, though, is not to use such methods.

There is no prohibition about citing this book as a reference in the exam. In fact, engineers have been doing so with previous editions for years. Engineering is engineering. As long as you use them correctly, the data, formulas, and principles are the same regardless of where you get them.

HOW TO SOLVE PROBLEMS CAREFULLY

Many points are lost to carelessness. Keep the following items in mind when you are solving the practice problems. Hopefully, these suggestions will be automatic to you in the exam.

- [ ] Reread the question. Did you answer every part?
- [ ] Did you use all of the given data?
- [ ] Did you use all of the given figures?
- [ ] Did you use all of the efficiencies given?
- [ ] Did you list all of your assumptions?
- [ ] Did you convert between feet and inches?
- [ ] Did you convert from gage to absolute pressures?
- [ ] Did you convert between pounds and kips?
- [ ] Did you recheck all data obtained from other sources, tables, and figures? (In finding the friction factor, for example, did you enter the Moody diagram at the correct Reynolds number?)
- [ ] Did you convert between radius and diameter?
- [ ] Did you use any symbols in your solution that need to be defined?
- [ ] Does your answer have units?
- [ ] Are your figures clearly labeled?
- [ ] Did you recheck all of your mathematical equations?
- [ ] Do the units cancel out in your calculations?
- [ ] Did you list the sources of any obscure data or methods?

SHOULD YOU TALK TO OTHER EXAMINEES AFTER THE EXAM?

The jury is out on this question. People react quite differently to the examination experience. Some people are energized. Most are exhausted. Some people need to unwind by talking with other examinees, describing every detail of their experience, and dissecting every examination question. Other people need lots of quiet space, and prefer just get into a hot tub to soak and sulk.

Since everyone who took the exam has seen it, you will not be violating your "oath of silence" if you talk about the details with other examinees. It's pretty difficult not to ask how someone else approached a problem that had you completely stumped. However, it is also very disquieting to think you did well on a problem, only to have someone tell you where you went wrong.

AND THEN THERE'S THE WAIT . . .

Waiting for the exam results is its own form of mental torture. There is no pattern to the release of results. None. The exam results are not released to all states simultaneously. They are not released by discipline. They are not released alphabetically by state or examinee name. The people who failed are not notified first, or last. Your coworker might receive his or her notification today, and you might wait another three weeks.

It all depends on when the work gets done. Some states have to approve the results at a board meeting. Some prepare the certificates before sending out notifications. Some states are more highly computerized than others. Some states have 50 examinees, while others have 5000. Some states are shut down by blizzards and hurricanes. Some states are understaffed and inadequately trained.

The size of the envelope that you receive does not mean anything. Some states send a big congratulations package and certificate. Some states send a big package with a new application to repeat the exam. Some states send a postcard. Some states send a one-page letter. You just have to open it to find out.

Check the Licensing Exam Forum at the PPI web site (www.ppi2pass.com) regularly to find out which states have released their results. You will find many other anxious examinees there.

Practice Problems 1-10

1. INTRODUCTION

The purpose of this chapter is to eliminate some of the confusion regarding the many units available for each engineering variable. In particular, an effort has been made to clarify the use of the so-called English systems, which for years have used the *pound* unit both for force and mass—a practice that has resulted in confusion even for those familiar with it.

2. COMMON UNITS OF MASS

The choice of a mass unit is the major factor in determining which system of units will be used in solving a problem. It is obvious that one will not easily end up with a force in pounds if the rest of the problem is stated in meters and kilograms. Actually, the choice of a mass unit determines more than whether a conversion factor will be necessary to convert from one system to another (e.g., between SI and English units). An inappropriate choice of a mass unit may actually require a conversion factor *within* the system of units.

The common units of mass are the gram, pound, kilogram, and slug.[1] There is nothing mysterious about these units. All represent different quantities of matter, as Fig. 1.1 illustrates. In particular, note that the pound and slug do not represent the same quantity of matter.[2]

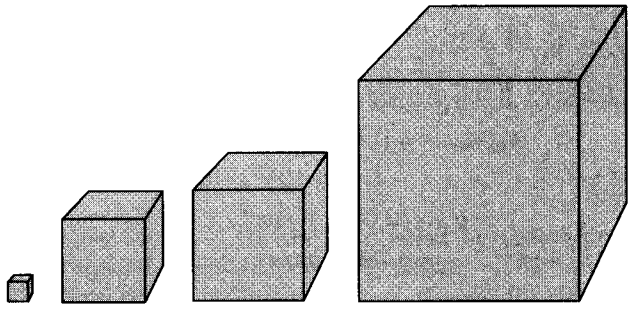

Figure 1.1 *Common Units of Mass*

3. MASS AND WEIGHT

In SI, *kilograms* are used for mass and *newtons* for weight (force). The units are different, and there is no confusion between the variables. However, for years the term *pound* has been used for both mass and weight. This usage has obscured the distinction between the two: mass is a constant property of an object; weight varies with the gravitational field. Even the conventional use of the abbreviations *lbm* and *lbf* (to distinguish between pounds-mass and pounds-force) has not helped eliminate the confusion.

It is true that an object with a mass of one pound will have an earthly weight of one pound, but this is true only on the earth. The weight of the same object will be much less on the moon. Therefore, care must be taken when working with mass and force in the same problem.

The relationship that converts mass to weight is familiar to every engineering student.

$$W = mg \qquad 1.1$$

Equation 1.1 illustrates that an object's weight will depend on the local acceleration of gravity as well as the object's mass. The mass will be constant, but gravity will depend on location. Mass and weight are not the same.

[1] Normally, one does not distinguish between a unit and a multiple of that unit, as is done here with the gram and the kilogram. However, these two units actually are bases for different consistent systems.

[2] A slug is equal to 32.1740 pounds-mass.

4. ACCELERATION OF GRAVITY

Gravitational acceleration on the earth's surface is usually taken as 32.2 ft/sec^2 or 9.81 m/s^2. These values are rounded from the more exact standard values of 32.1740 ft/sec^2 and 9.8066 m/s^2. However, the need for greater accuracy must be evaluated on a problem-by-problem basis. Usually, three significant digits are adequate, since gravitational acceleration is not constant anyway but is affected by location (primarily latitude and altitude) and major geographical features.

The term *standard gravity*, g_0, is derived from the acceleration at essentially any point at sea level and approximately 45° N latitude. If additional accuracy is needed, the gravitational acceleration can be calculated from Eq. 1.2. This equation neglects the effects of large land and water masses. ϕ is the latitude in degrees.

$$\begin{aligned} g_{\text{surface}} &= g'[1 + (5.305 \times 10^{-3}) \sin^2 \phi \\ &\quad - (5.9 \times 10^{-6}) \sin^2 2\phi] \qquad 1.2 \\ g' &= 32.0881 \text{ ft/sec}^2 \\ &= 9.78045 \text{ m/s}^2 \end{aligned}$$

If the effects of the earth's rotation are neglected, the gravitational acceleration at an altitude h above the earth's surface is given by Eq. 1.3. R_e is the earth's radius.

$$\begin{aligned} g_h &= g_{\text{surface}} \left(\frac{R_e}{R_e + h} \right)^2 \qquad 1.3 \\ R_e &= 3960 \text{ mi} \\ &= 6.37 \times 10^6 \text{ m} \end{aligned}$$

5. CONSISTENT SYSTEMS OF UNITS

A set of units used in a calculation is said to be *consistent* if no conversion factors are needed.[3] For example, a moment is calculated as the product of a force and a lever arm length.

$$M = Fd \qquad 1.4$$

A calculation using Eq. 1.4 would be consistent if M was in newton-meters, F was in newtons, and d was in meters. The calculation would be inconsistent if M was in ft-kips, F was in kips, and d was in inches (because a conversion factor of 1/12 would be required).

The concept of a consistent calculation can be extended to a system of units. A *consistent system of units* is one in which no conversion factors are needed for any calculation. For example, Newton's second law of motion can be written without conversion factors. Newton's second law simply states that the force required to accelerate an object is proportional to the acceleration of the object. The constant of proportionality is the object's mass.

$$F = ma \qquad 1.5$$

Notice that Eq. 1.5 is $F = ma$, not $F = Wa/g$ or $F = ma/g_c$. Equation 1.5 is consistent: it requires no conversion factors. This means that in a consistent system where conversion factors are not used, once the units of m and a have been selected, the units of F are fixed. This has the effect of establishing units of work and energy, power, fluid properties, and so on.

It should be mentioned that the decision to work with a consistent set of units is desirable but unnecessary, depending on tradition and environment. Problems in fluid flow and thermodynamics are routinely solved in the United States with inconsistent units. This causes no more of a problem than working with inches and feet when calculating a moment. It is necessary only to use the proper conversion factors.

6. THE ENGLISH ENGINEERING SYSTEM

Through common and widespread use, pounds-mass (lbm) and pounds-force (lbf) have become the standard units for mass and force in the *English Engineering System*. (The English Engineering System is used in this book.)

There are subjects in the United States where the practice of using pounds for mass is firmly entrenched. For example, most thermodynamics, fluid flow, and heat transfer problems have traditionally been solved using the units of lbm/ft^3 for density, Btu/lbm for enthalpy, and Btu/lbm-°F for specific heat. Unfortunately, some equations contain both lbm-related and lbf-related variables, as does the steady flow conservation of energy equation, which combines enthalpy in Btu/lbm with pressure in lbf/ft^2.

The units of pounds-mass and pounds-force are as different as the units of gallons and feet, and they cannot be canceled. A mass conversion factor, g_c, is needed to make the equations containing lbf and lbm dimensionally consistent. This factor is known as the *gravitational constant* and has a value of 32.1740 lbm-ft/lbf-sec^2. The numerical value is the same as the standard acceleration of gravity, but g_c is not the local gravitational acceleration, g.[4] g_c is a conversion constant, just as 12.0 is the conversion factor between feet and inches.

The English Engineering System is an inconsistent system as defined according to Newton's second law. $F = ma$ cannot be written if lbf, lbm, and ft/sec^2 are the units used. The g_c term must be included.

$$F \text{ in lbf} = \frac{(m \text{ in lbm}) \left(a \text{ in } \dfrac{\text{ft}}{\text{sec}^2} \right)}{g_c \text{ in } \dfrac{\text{lbm-ft}}{\text{lbf-sec}^2}} \qquad 1.6$$

It is important to note in Eq. 1.6 that g_c does more than "fix the units." Since g_c has a numerical value of

[3] The terms *homogeneous* and *coherent* are also used to describe a consistent set of units.

[4] It is acceptable (and recommended) that g_c be rounded to the same number of significant digits as g. Therefore, a value of 32.2 for g_c would typically be used.

32.174, it actually changes the calculation numerically. A force of 1.0 pound will not accelerate a 1.0-pound mass at the rate of 1.0 ft/sec^2.

In the English Engineering System, work and energy are typically measured in ft-lbf (mechanical systems) or in British thermal units, Btu (thermal and fluid systems). One Btu is equal to 778.17 ft-lbf.

Example 1.1

Calculate the weight in lbf of a 1.00 lbm object in a gravitational field of 27.5 ft/sec^2.

Solution

From Eq. 1.6,

$$F = \frac{ma}{g_c} = \frac{(1.00 \text{ lbm})\left(27.5 \frac{\text{ft}}{\text{sec}^2}\right)}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}$$

$$= 0.854 \text{ lbf}$$

7. OTHER FORMULAS AFFECTED BY INCONSISTENCY

It is not a significant burden to include g_c in a calculation, but it may be difficult to remember when g_c should be used. Knowing when to include the gravitational constant can be learned through repeated exposure to the formulas in which it is needed, but it is safer to carry the units along in every calculation.

The following is a representative (but not exhaustive) listing of formulas that require the g_c term. In all cases, it is assumed that the standard English Engineering System units will be used.

- kinetic energy

$$E = \frac{mv^2}{2g_c} \quad \text{(in ft-lbf)} \qquad 1.7$$

- potential energy

$$E = \frac{mgz}{g_c} \quad \text{(in ft-lbf)} \qquad 1.8$$

- pressure at a depth

$$p = \frac{\rho g h}{g_c} \quad \text{(in lbf/ft}^2\text{)} \qquad 1.9$$

Example 1.2

A rocket with a mass of 4000 lbm travels at 27,000 ft/sec. What is its kinetic energy in ft-lbf?

Solution

From Eq. 1.7,

$$E_k = \frac{mv^2}{2g_c} = \frac{(4000 \text{ lbm})\left(27{,}000 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)}$$

$$= 4.53 \times 10^{10} \text{ ft-lbf}$$

8. WEIGHT AND WEIGHT DENSITY

Weight is a force exerted on an object due to its placement in a gravitational field. If a consistent set of units is used, Eq. 1.1 can be used to calculate the weight of a mass. In the English Engineering System, however, Eq. 1.10 must be used.

$$W = \frac{mg}{g_c} \qquad 1.10$$

Both sides of Eq. 1.10 can be divided by the volume of an object to derive the *weight density*, γ, of the object. Equation 1.11 illustrates that the weight density (in lbf/ft^3) can also be calculated by multiplying the mass density (in lbm/ft^3) by g/g_c. Since g and g_c usually have the same numerical values, the only effect of Eq. 1.12 is to change the units of density.

$$\frac{W}{V} = \left(\frac{m}{V}\right)\left(\frac{g}{g_c}\right) \qquad 1.11$$

$$\gamma = \frac{W}{V} = \left(\frac{m}{V}\right)\left(\frac{g}{g_c}\right) = \frac{\rho g}{g_c} \qquad 1.12$$

Weight does not occupy volume. Only mass has volume. The concept of weight density has evolved to simplify certain calculations, particularly fluid calculations. For example, pressure at a depth is calculated from Eq. 1.13. (Compare this with Eq. 1.9.)

$$p = \gamma h \qquad 1.13$$

9. THE ENGLISH GRAVITATIONAL SYSTEM

Not all English systems are inconsistent. Pounds can still be used as the unit of force as long as pounds are not used as the unit of mass. Such is the case with the consistent *English Gravitational System*.

If acceleration is given in ft/sec^2, the units of mass for a consistent system of units can be determined from Newton's second law. The combination of units in Eq. 1.14 is known as a *slug*. g_c is not needed at all since this system is consistent. It would be needed only to convert slugs to another mass unit.

$$\text{units of } m = \frac{\text{units of } F}{\text{units of } a}$$

$$= \frac{\text{lbf}}{\frac{\text{ft}}{\text{sec}^2}} = \frac{\text{lbf-sec}^2}{\text{ft}} \qquad 1.14$$

Slugs and pounds-mass are not the same, as Fig. 1.1 illustrates. However, both are units for the same quantity: mass. Equation 1.15 will convert between slugs and pounds-mass.

$$\text{no. of slugs} = \frac{\text{no. of lbm}}{g_c} \qquad 1.15$$

It is important to recognize that the number of slugs is not derived by dividing the number of pounds-mass by the local gravity. g_c is used regardless of the local gravity. The conversion between feet and inches is not dependent on local gravity; neither is the conversion between slugs and pounds-mass.

Since the English Gravitational System is consistent, Eq. 1.16 can be used to calculate weight. Notice that the local gravitational acceleration is used.

$$W \text{ in lbf} = (m \text{ in slugs}) \left(g \text{ in } \frac{\text{ft}}{\text{sec}^2} \right) \qquad 1.16$$

10. THE ABSOLUTE ENGLISH SYSTEM

The obscure *Absolute English System* takes the approach that mass must have units of pounds-mass (lbm) and the units of force can be derived from Newton's second law. The units for F cannot be simplified any more than they are in Eq. 1.17. This particular combination of units is known as a *poundal*.[5] A poundal is not the same as a pound.

$$\begin{aligned} \text{units of } F &= (\text{units of } m)(\text{units of } a) \\ &= (\text{lbm}) \left(\frac{\text{ft}}{\text{sec}^2} \right) \\ &= \frac{\text{lbm-ft}}{\text{sec}^2} \end{aligned} \qquad 1.17$$

Poundals have not seen widespread use in the United States. The English Gravitational System (using slugs for mass) has greatly eclipsed the Absolute English System in popularity. Both are consistent systems, but there seems to be little need for poundals in modern engineering.

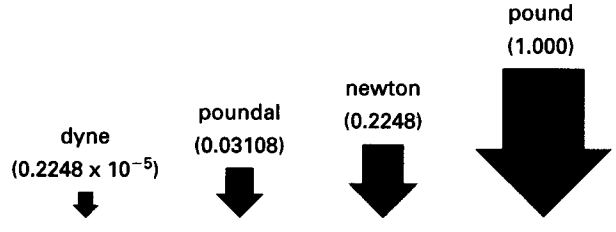

Figure 1.2 *Common Force Units*

[5]A poundal is equal to 0.03108 pounds-force.

11. METRIC SYSTEMS OF UNITS

Strictly speaking, a *metric system* is any system of units that is based on meters or parts of meters. This broad definition includes *mks systems* (based on meters, kilograms, and seconds) as well as *cgs systems* (based on centimeters, grams, and seconds).

Metric systems avoid the pounds-mass versus pounds-force ambiguity in two ways. First, a unit of weight is not established at all. All quantities of matter are specified as mass. Second, force and mass units do not share a common name.

The term *metric system* is not explicit enough to define which units are to be used for any given variable. For example, within the cgs system there is variation in how certain electrical and magnetic quantities are represented (resulting in the ESU and EMU systems). Also, within the mks system, it is common practice in some industries to use kilocalories as the unit of thermal energy, while the SI unit for thermal energy is the joule. Thus, there is a lack of uniformity even within the metricated engineering community.[6]

The "metric" parts of this book use SI, which is the most developed and codified of the so-called metric systems.[7] There will be occasional variances with local engineering custom, but it is difficult to anticipate such variances within a book that must itself be consistent.[8]

12. THE cgs SYSTEM

The *cgs system* is used widely by chemists and physicists. It is named for the three primary units used to construct its derived variables: the centimeter, the gram, and the second.

When Newton's second law is written in the cgs system, the following combination of units results.

$$\begin{aligned} \text{units of force} &= (m \text{ in g}) \left(a \text{ in } \frac{\text{cm}}{\text{s}^2} \right) \\ &= \text{g·cm/s}^2 \end{aligned} \qquad 1.18$$

This combination of units for force is known as a *dyne*. Energy variables in the cgs system have units of dyne·cm or, equivalently, $\text{g·cm}^2/\text{s}^2$. This combination is known as an *erg*. There is no uniformly accepted unit of power in the cgs system, although calories per second is frequently used.

[6]In the "field test" of the metric system conducted over the past 200 years, other conventions are to use kilograms-force (kgf) instead of newtons and kgf/cm^2 for pressure (instead of pascals).

[7]SI units are an outgrowth of the *General Conference of Weights and Measures*, an international treaty organization that established the *Système International d'Unites (International System of Units)* in 1960. The United States subscribed to this treaty in 1975.

[8]Conversion to pure SI units is essentially complete in Australia, Canada, New Zealand, and South Africa. The use of nonstandard metric units is more common among European civil engineers, who have had little need to deal with the inertial properties of mass. However, even the American Society of Civil Engineers declared its support for SI units in 1985.

The fundamental volume unit in the cgs system is the cubic centimeter (cc). Since this is the same volume as one thousandth of a liter, units of milliliters (mL) are also used.

13. SI UNITS (THE mks SYSTEM)

SI units comprise an *mks system* (so named because it uses the meter, kilogram, and second as base units). All other units are derived from the base units, which are completely listed in Table 1.1. This system is fully consistent, and there is only one recognized unit for each physical quantity (variable).

Table 1.1 *SI Base Units*

quantity	name	symbol
length	meter	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
temperature	kelvin	K
amount of substance	mole	mol
luminous intensity	candela	cd

Two types of units are used: base units and derived units. The *base units* are dependent only on accepted standards or reproducible phenomena. The *derived units* (Tables 1.2 and 1.3) are made up of combinations of base units. The old *supplementary units* (Table 1.4) were classified as derived units in 1995.

Table 1.2 *Some SI Derived Units with Special Names*

quantity	name	symbol	expressed in terms of other units
frequency	hertz	Hz	1/s
force	newton	N	$kg \cdot m/s^2$
pressure, stress	pascal	Pa	N/m^2
energy, work, quantity of heat	joule	J	N·m
power, radiant flux	watt	W	J/s
quantity of electricity, electric charge	coulomb	C	
electric potential, potential difference, electromotive force	volt	V	W/A
electric capacitance	farad	F	C/V
electric resistance	ohm	Ω	V/A
electric conductance	siemen	S	A/V
magnetic flux	weber	Wb	V·s
magnetic flux density	tesla	T	Wb/m^2
inductance	henry	H	Wb/A
luminous flux	lumen	lm	
illuminance	lux	lx	lm/m^2

In addition, there is a set of non-SI units that may be used. This concession is primarily due to the significance and widespread acceptance of these units. Use of the non-SI units listed in Table 1.5 will usually create an inconsistent expression requiring conversion factors.

Table 1.3 *Some SI Derived Units*

quantity	description	symbol
area	square meter	m^2
volume	cubic meter	m^3
speed—linear	meter per second	m/s
—angular	radian per second	rad/s
acceleration—linear	meter per second squared	m/s^2
—angular	radian per second squared	rad/s^2
density, mass density	kilogram per cubic meter	kg/m^3
concentration (of amount of substance)	mole per cubic meter	mol/m^3
specific volume	cubic meter per kilogram	m^3/kg
luminance	candela per square meter	cd/m^2
absolute viscosity	pascal second	Pa·s
kinematic viscosity	square meters per second	m^2/s
moment of force	newton meter	N·m
surface tension	newton per meter	N/m
heat flux density, irradiance	watt per square meter	W/m^2
heat capacity, entropy	joule per kelvin	J/K
specific heat capacity, specific entropy	joule per kilogram kelvin	J/kg·K
specific energy	joule per kilogram	J/kg
thermal conductivity	watt per meter kelvin	W/m·K
energy density	joule per cubic meter	J/m^3
electric field strength	volt per meter	V/m
electric charge density	coulomb per cubic meter	C/m^3
surface density of charge, flux density	coulomb per square meter	C/m^2
permittivity	farad per meter	F/m
current density	ampere per square meter	A/m^2
magnetic field strength	ampere per meter	A/m
permeability	henry per meter	H/m
molar energy	joule per mole	J/mol
molar entropy, molar heat capacity	joule per mole kelvin	J/mol·K
radiant intensity	watt per steradian	W/sr

Table 1.4 *SI Supplementary Units*[a]

quantity	name	symbol
plane angle	radian	rad
solid angle	steradian	sr

[a] classified as derived units in 1995.

The SI unit of force can be derived from Newton's second law. This combination of units for force is known as a *newton*.

$$\text{units of force} = (m \text{ in kg})\left(a \text{ in } \frac{\text{m}}{\text{s}^2}\right) = \text{kg}\cdot\text{m/s}^2 \qquad 1.19$$

Energy variables in SI units have units of N·m or, equivalently, $kg \cdot m^2/s^2$. Both of these combinations are known as a *joule*. The units of power are joules per second, equivalent to a *watt*.

Example 1.3

A 10 kg block hangs from a cable. What is the tension in the cable? (Standard gravity equals 9.81 m/s^2.)

Solution

$$\begin{aligned} F &= mg \\ &= (10\ \text{kg})\left(9.81\ \frac{\text{m}}{\text{s}^2}\right) \\ &= 98.1\ \text{kg}\cdot\text{m/s}^2\ (98.1\ \text{N}) \end{aligned}$$

Example 1.4

A 10 kg block is raised vertically 3 m. What is the change in potential energy?

Solution

$$\begin{aligned} \Delta E_p &= mg\Delta h \\ &= (10\ \text{kg})\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(3\ \text{m}) \\ &= 294\ \text{kg}\cdot\text{m}^2/\text{s}^2\ (294\ \text{J}) \end{aligned}$$

14. RULES FOR USING SI UNITS

In addition to having standardized units, the set of SI units also has rigid syntax rules for writing the units and combinations of units. Each unit is abbreviated with a specific symbol. The following rules for writing and combining these symbols should be adhered to.

- The expressions for derived units in symbolic form are obtained by using the mathematical signs of multiplication and division. For example, units of velocity are m/s. Units of torque are N·m (not N-m or Nm).
- Scaling of most units is done in multiples of 1000.
- The symbols are always printed in roman type, regardless of the type used in the rest of the text. The only exception to this is in the use of the symbol for liter, where the use of the lower case "el" (l) may be confused with the numeral one (1). In this case, "liter" should be written out in full, or the script ℓ or L used. (L is used in this book.)

Table 1.5 *Acceptable Non-SI Units*

quantity	unit name	symbol or abbreviation	relationship to SI unit
area	hectare	ha	1 ha = 10 000 m^2
energy	kilowatt-hour	kW·h	1 kW·h = 3.6 MJ
mass	metric ton[a]	t	1 t = 1000 kg
plane angle	degree (of arc)	°	1° = 0.017 453 rad
speed of rotation	revolution per minute	r/min	1 r/min = $2\pi/60$ rad/s
temperature interval	degree Celsius	°C	1°C = 1K
time	minute	min	1 min = 60 s
	hour	h	1 h = 3600 s
	day (mean solar)	d	1 d = 86 400 s
	year (calendar)	a	1 a = 31 536 000 s
velocity	kilometer per hour	km/h	1 km/h = 0.278 m/s
volume	liter[b]	L	1 L = 0.001 m^3

[a]The international name for metric ton is *tonne*. The metric ton is equal to the *megagram* (Mg).
[b]The international symbol for liter is the lowercase l, which can be easily confused with the numeral 1. Several English-speaking countries have adopted the script ℓ or uppercase L (as does this book) as a symbol for liter in order to avoid any misinterpretation.

- Symbols are not pluralized: 1 kg, 45 kg (not 45 kgs).
- A period after a symbol is not used, except when the symbol occurs at the end of a sentence.
- When symbols consist of letters, there is always a full space between the quantity and the symbols: 45 kg (not 45kg). However, when the first character of a symbol is not a letter, no space is left: 32°C (not 32° C or 32 °C); or 42° 12′ 45″ (not 42 ° 12 ′ 45 ″).
- All symbols are written in lowercase, except when the unit is derived from a proper name: m for meter; s for second; A for ampere, Wb for weber, N for newton, W for watt.
- Prefixes are printed without spacing between the prefix and the unit symbol (e.g., km is the symbol for kilometer).
- In text, symbols should be used when associated with a number. However, when no number is involved, the unit should be spelled out. Examples: The area of the carpet is 16 m^2, not 16 square meters. Carpet is sold by the square meter, not by the m^2.
- Where a decimal fraction of a unit is used, a zero should always be placed before the decimal marker: 0.45 kg (not .45 kg). This practice draws attention to the decimal marker and helps avoid errors of scale.

Table 1.6 *SI Prefixes*[a]

prefix	symbol	value
exa	E	10^{18}
peta	P	10^{15}
tera	T	10^{12}
giga	G	10^{9}
mega	M	10^{6}
kilo	k	10^{3}
hecto	h	10^{2}
deka (or "deca")	da	10^{1}
deci	d	10^{-1}
centi	c	10^{-2}
milli	m	10^{-3}
micro	μ	10^{-6}
nano	n	10^{-9}
pico	p	10^{-12}
femto	f	10^{-15}
atto	a	10^{-18}

[a]There is no "B" (billion) prefix. In fact, the word "billion" means 10^9 in the United States but 10^{12} in most other countries. This unfortunate ambiguity is handled by avoiding the use of the term billion.

- A practice in some countries is to use a comma as a decimal marker, while the practice in North America, the United Kingdom, and some other countries is to use a period (or dot) as the decimal marker. Furthermore, in some countries that use the decimal comma, a dot is frequently used to divide long numbers into groups of three. Because of these differing practices, spaces must be used instead of commas to separate long lines of digits into easily readable blocks of three digits with respect to the decimal marker: 32 453.246 072 5. A space (half-space preferred) is optional with a four-digit number: 1 234 or 1234.
- Some confusion may arise with the word "tonne" (1000 kg). When this word occurs in French text of Canadian origin, the meaning may be a ton of 2000 pounds.

15. PRIMARY DIMENSIONS

Regardless of the system of units chosen, each variable representing a physical quantity will have the same *primary dimensions*. For example, velocity may be expressed in miles per hour (mph) or meters per second (m/s), but both units have dimensions of length per unit time. Length and time are two of the primary dimensions, as neither can be broken down into more basic dimensions. The concept of primary dimensions is useful when converting little-used variables between different systems of units, as well as in correlating experimental results (i.e., dimensional analysis).

There are three different sets of primary dimensions in use.[9] In the $ML\theta T$ system, the primary dimensions are mass (M), length (L), time (θ), and temperature (T). Notice that all symbols are uppercase. In order to avoid confusion between time and temperature, the Greek letter theta is used for time.[10]

All other physical quantities can be derived from these primary dimensions.[11] For example, work in SI units has units of N·m. Since a newton is a kg·m/s^2, the primary dimensions of work are ML^2/θ^2. The primary dimensions for many important engineering variables are shown in Table 1.7. If it is more convenient to stay with traditional English units, it may be more desirable to work in the $FML\theta TQ$ system (sometimes called the *engineering dimensional system*). This system adds the primary dimensions of force (F) and heat (Q). Thus, work (ft-lbf in the English system) has the primary dimensions of FL. (Compare this with the primary dimensions for work in the $ML\theta T$ system.) Thermodynamic variables are similarly simplified.

Dimensional analysis will be more conveniently carried out when one of the four-dimension systems ($ML\theta T$ or $FL\theta T$) is used. Whether the $ML\theta T$, $FL\theta T$, or $FML\theta TQ$ system is used depends on what is being derived and who will be using it, and whether or not a consistent set of variables is desired. Conversion constants such as g_c and J will almost certainly be required if the $ML\theta T$ system is used to generate variables for use in the English systems. It is also much more convenient to use the $FML\theta TQ$ system when working in the fields of thermodynamics, fluid flow, heat transfer, and so on.

16. DIMENSIONLESS GROUPS

A *dimensionless group* is derived as a ratio of two forces or other quantities. Considerable use of dimensionless groups is made in certain subjects, notably fluid mechanics and heat transfer. For example, the Reynolds number, Mach number, and Froude number are used to distinguish between distinctly different flow regimes in pipe flow, compressible flow, and open channel flow, respectively.

Table 1.8 contains information about the most common dimensionless groups used in fluid mechanics and heat transfer.

[9]One of these, the $FL\theta T$ system, is not discussed here but appears in Table 1.7.

[10]This is the most common usage. There is a lack of consistency in the engineering world about the symbols for the primary dimensions in dimensional analysis. Some writers use t for time instead of θ. Some use H for heat instead of Q. And, in the worst mix-up of all, some have reversed the use of T and θ.

[11]A *primary dimension* is the same as a *base unit* in the SI set of units. The SI units add several other base units, as shown in Table 1.1, to deal with variables that are difficult to derive in terms of the four primary base units.

Table 1.7 *Dimensions of Common Variables*

variable	dimensional system $ML\theta T$	$FL\theta T$	$FML\theta TQ$
mass (m)	M	$F\theta^2/L$	M
force (F)	ML/θ^2	F	F
length (L)	L	L	L
time (θ)	θ	θ	θ
temperature (T)	T	T	T
work (W)	ML^2/θ^2	FL	FL
heat (Q)	ML^2/θ^2	FL	Q
acceleration (a)	L/θ^2	L/θ^2	L/θ^2
frequency (N)	$1/\theta$	$1/\theta$	$1/\theta$
area (A)	L^2	L^2	L^2
coefficient of thermal expansion (β)	$1/T$	$1/T$	$1/T$
density (ρ)	M/L^3	$F\theta^2/L^4$	M/L^3
dimensional constant (g_c)	1.0	1.0	ML/θ^2F
specific heat at constant pressure (c_p); at constant volume (c_v)	L^2/θ^2T	L^2/θ^2T	Q/MT
heat transfer coefficient (h); overall (U)	M/θ^3T	$F/\theta LT$	$Q/\theta L^2T$
power (P)	ML^2/θ^3	FL/θ	FL/θ
heat flow rate ($\dot{Q}$)	ML^2/θ^3	FL/θ	Q/θ
kinematic viscosity (ν)	L^2/θ	L^2/θ	L^2/θ
mass flow rate ($\dot{m}$)	M/θ	$F\theta/L$	M/θ
mechanical equivalent of heat (J)	–	–	FL/Q
pressure (p)	$M/L\theta^2$	F/L^2	F/L^2
surface tension (σ)	M/θ^2	F/L	F/L
angular velocity (ω)	$1/\theta$	$1/\theta$	$1/\theta$
volumetric flow rate ($\dot{m}/\rho = \dot{V}$)	L^3/θ	L^3/θ	L^3/θ
conductivity (k)	ML/θ^3T	$F/\theta T$	$Q/L\theta T$
thermal diffusivity (α)	L^2/θ	L^2/θ	L^2/θ
velocity (v)	L/θ	L/θ	L/θ
viscosity, absolute (μ)	$M/L\theta$	$F\theta/L^2$	$F\theta/L^2$
volume (V)	L^3	L^3	L^3

17. LINEAL AND BOARD FOOT MEASUREMENTS

The term *lineal* is often mistaken as a typographical error for *linear*. Although "lineal" has its own specific meaning slightly different from "linear," the two are often used interchangeably by engineers.[12] The adjective *lineal* is often encountered in the building trade (e.g., 12 lineal feet of lumber), where the term is used to distinguish it from board feet measurement.

A *board foot* (abbreviated bd-ft) is not a measure of length. Rather, it is a measure of volume used with lumber. Specifically, a board foot is equal to 144 in^3 (2.36×10^{-3} m^3). The name is derived from the volume of a board 1 foot square and 1 inch thick. In that sense, it is parallel in concept to the acre-foot. Since lumber cost is directly related to lumber weight and volume, the board foot unit is used in determining the overall lumber cost.

[12] *Lineal* is best used when discussing a line of succession (e.g., a lineal descendant of a particular person). *Linear* is best used when discussing length (e.g., a linear dimension of a room).

18. DIMENSIONAL ANALYSIS

Dimensional analysis is a means of obtaining an equation that describes some phenomenon without understanding the mechanism of the phenomenon. The most serious limitation is the need to know beforehand which variables influence the phenomenon. Once these are known or assumed, dimensional analysis can be applied by a routine procedure.

The first step is to select a system of primary dimensions. (See Sec. 15.) Usually the $ML\theta T$ system is used, although this choice may require the use of g_c and J in the final results. The dimensional formulas and symbols for variables most frequently encountered are given in Table 1.7.

The second step is to write a functional relationship between the dependent variable and the independent variable, x_i.

$$y = f(x_1, x_2, \ldots, x_m) \qquad 1.20$$

This function can be expressed as an exponentiated series. The $C_1, a_i, b_i \ldots, z_i$ in Eq. 1.21 are unknown constants.

$$y = C_1 x_1^{a_1} x_2^{b_1} x_3^{c_1} \ldots x_m^{z_1} + C_2 x_1^{a_2} x_2^{b_2} x_3^{c_2} \ldots x_m^{z_2} + \cdots \qquad 1.21$$

The key to solving Eq. 1.21 is that each term on the right-hand side must have the same dimensions as y. Simultaneous equations are used to determine some of the a_i, b_i, c_i, and z_i. Experimental data are required to determine the C_i and remaining exponents. In most analyses, it is assumed that the $C_i = 0$ for $i \geq 2$.

Since this method requires working with m different variables and n different independent dimensional quantities (such as M, L, θ, and T), an easier method is desirable. One simplification is to combine the m variables into dimensionless groups called *pi-groups*. (See Table 1.8.)

If these dimensionless groups are represented by $\pi_1, \pi_2, \pi_3, \ldots, \pi_k$, the equation expressing the relationship between the variables is given by the *Buckingham π-theorem*.

$$f(\pi_1, \pi_2, \pi_3 \ldots, \pi_k) = 0 \qquad 1.22$$

$$k = m - n \qquad 1.23$$

The dimensionless pi-groups are usually found from the m variables according to an intuitive process.

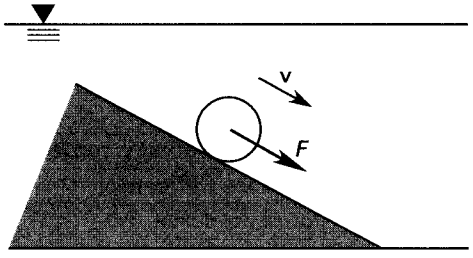

Table 1.8 *Common Dimensionless Groups*

name	symbol	formula	interpretation
Biot number	Bi	$\frac{hL}{k_s}$	$\frac{\text{surface conductance}}{\text{internal conduction of solid}}$
Cauchy number	Ca	$\frac{\mathrm{v}^2}{\frac{B_s}{\rho}} = \frac{\mathrm{v}^2}{a^2}$	$\frac{\text{inertia force}}{\text{compressive force}} = \text{Mach number}^2$
Eckert number	Ec	$\frac{\mathrm{v}^2}{2c_p\,\Delta T}$	$\frac{\text{temperature rise due to energy conversion}}{\text{temperature difference}}$
Euler number	Eu	$\frac{\Delta p}{\rho V^2}$	$\frac{\text{pressure force}}{\text{inertia force}}$
Fourier number	Fo	$\frac{kt}{\rho c_p L^2} = \frac{\alpha t}{L^2}$	$\frac{\text{rate of conduction of heat}}{\text{rate of storage of energy}}$
Froude number[a]	Fr	$\frac{\mathrm{v}^2}{gL}$	$\frac{\text{inertia force}}{\text{gravity force}}$
Graetz number[a]	Gz	$\left(\frac{D}{L}\right)\left(\frac{\mathrm{v}\rho c_p D}{k}\right)$	$\frac{\frac{(\mathrm{Re})(\mathrm{Pr})}{L/D}}{\frac{\text{heat transfer by convection in entrance region}}{\text{heat transfer by conduction}}}$

Stanton number	St	$\frac{h}{\mathrm{v}\rho c_p} = \frac{h}{c_p G}$	$\frac{\text{heat transfer at wall}}{\text{energy transported by stream}}$
Stokes number	Sk	$\frac{\Delta p L}{\mu\,\mathrm{v}}$	$\frac{\text{pressure force}}{\text{viscous force}}$
Strouhal number[a]	Sl	$\frac{L}{t\mathrm{v}} = \frac{L\omega}{\mathrm{v}}$	$\frac{\text{frequency of vibration}}{\text{characteristic frequency}}$
Weber number	We	$\frac{\rho \mathrm{v}^2 L}{\sigma}$	$\frac{\text{inertia force}}{\text{surface tension force}}$

[a]Multiple definitions exist.

Example 1.5

A solid sphere rolls down a submerged incline. Find an equation for the velocity, v.

Solution

Assume that the velocity depends on the force, F, due to gravity, the diameter of the sphere, D, the density of the fluid, ρ, and the viscosity of the fluid, μ.

$$\mathrm{v} = f(F, D, \rho, \mu) = CF^a D^b \rho^c \mu^d$$

This equation can be written in terms of the primary dimensions of the variables.

$$\frac{L}{\theta} = C\left(\frac{ML}{\theta^2}\right)^a L^b \left(\frac{M}{L^3}\right)^c \left(\frac{M}{L\theta}\right)^d$$

Since L on the left-hand side has an implied exponent of one, a necessary condition is

$$1 = a + b - 3c - d \qquad (L)$$

Similarly, the other necessary conditions are

$$-1 = -2a - d \qquad (\theta)$$
$$0 = a + c + d \qquad (M)$$

Solving simultaneously yields

$$b = -1$$
$$c = a - 1$$
$$d = 1 - 2a$$
$$\mathrm{v} = CF^a D^{-1} \rho^{a-1} \mu^{1-2a}$$
$$= C\left(\frac{\mu}{D\rho}\right)\left(\frac{F\rho}{\mu^2}\right)^a$$

C and a must be determined experimentally.

PRACTICE PROBLEMS

1. Convert 250°F to degrees Celsius.

(A) 115°C
(B) 121°C
(C) 124°C
(D) 420°C

The answer is (B).

2. Convert the Stefan-Boltzmann constant (0.1713×10^{-8} Btu/ft^2-hr-°R^4) from English to SI units.

(A) 5.14×10^{-10} W/m^2·K^4
(B) 0.95×10^{-8} W/m^2·K^4
(C) 5.67×10^{-8} W/m^2·K^4
(D) 7.33×10^{-6} W/m^2·K^4

The answer is (C).

3. How many U.S. tons (2000 lbm per ton) of coal with a heating value of 13,000 Btu/lbm must be burned to provide as much energy as a complete nuclear conversion of 1 g of its mass? (Hint: Use Einstein's equation: $E = mc^2$.)

(A) 1.7 tons
(B) 14 tons
(C) 779 tons
(D) 3300 tons

The answer is (D).

11. Surface Finish 2-4

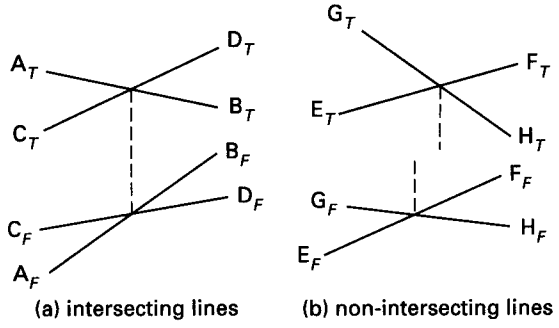

Figure 2.1 *Intersecting and Non-Intersecting Lines*

1. NORMAL VIEWS OF LINES AND PLANES

A *normal view* of a line is a perpendicular projection of the line onto a viewing plane parallel to the line. In the normal view, all points of the line are equidistant from the observer. Therefore, the true length of a line is viewed and can be measured.

Generally, however, a line will be viewed from an oblique position and will appear shorter than it actually is. The normal view can be constructed by drawing an auxiliary view (see Sec. 5) from the orthographic view.[2]

Similarly, a normal view of a plane figure is a perpendicular projection of the figure onto a viewing plane parallel to the plane of the figure. All points of the plane are equidistant from the observer. Therefore, the true size and shape of any figure in the plane can be determined.

2. INTERSECTING AND PERPENDICULAR LINES

A single orthographic view is not sufficient to determine whether two lines intersect. However, if two or more views show the lines as having the same common point (i.e., crossing at the same position in space), then the lines intersect. In Fig. 2.1, the subscripts F and T refer to front and top views, respectively.

According to the *perpendicular line principle*, two perpendicular lines appear perpendicular only in a normal view of either one or both of the lines. Conversely, if two lines appear perpendicular in any view, the lines are perpendicular only if the view is a normal view of one or both of the lines.

3. TYPES OF VIEWS

Objects can be illustrated in several different ways depending on the number of views, the angle of observation, and the degree of artistic latitude taken for the purpose of simplifying the drawing process.[3] Table 2.1 categorizes the types of views.

Table 2.1 *Types of Views of Objects*

- orthographic views
  - principal views
  - auxiliary views
  - oblique views
    - cavalier projection
    - cabinet projection
    - clinographic projection
    - axonometric views
      - isometric
      - dimetric
      - trimetric
- perspective views
  - parallel perspective
  - angular perspective

[1]This chapter is not meant to show "how to do it" as much as it is to present the conventions and symbols of engineering drawing.
[2]The technique for constructing a normal view is covered in engineering drafting texts.
[3]The omission of perspective from a drawing is an example of a step taken to simplify the drawing process.

The different types of views are easily distinguished by their *projectors* (i.e., projections of parallel lines on the object). For a cube, there are three sets of projectors corresponding to the three perpendicular axes. In an *orthographic (orthogonal) view*, the projectors are parallel. In a *perspective (central) view*, some or all of the projectors converge to a point.

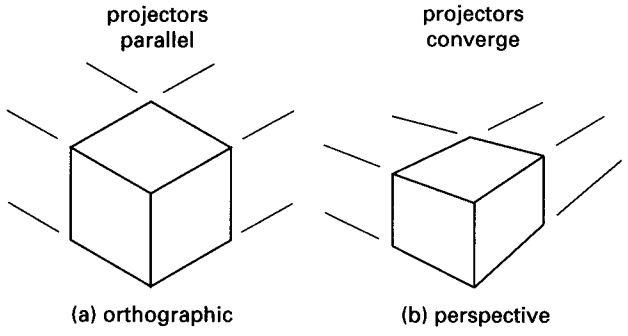

Figure 2.2 *Orthographic and Perspective Views of a Block*

4. PRINCIPAL (ORTHOGRAPHIC) VIEWS

In a *principal view* (also known as a *planar view*), one of the sets of projectors is normal to the view. That is, one of the planes of the object is seen in a normal view. The other two sets of projectors are orthogonal and are usually oriented horizontally and vertically on the paper. Because background details of an object may not be visible in a principal view, it is necessary to have at least three principal views to completely illustrate a symmetrical object. At most, six principal views will be needed to illustrate complex objects.

The relative positions of the six views have been standardized and are shown in Fig. 2.3, which also defines the *width* (also known as *depth*), *height*, and *length* of the object. The views that are not needed to illustrate features or provide dimensions (i.e., *redundant views*) can be omitted. The usual combination selected consists of the top, front, and right side views.

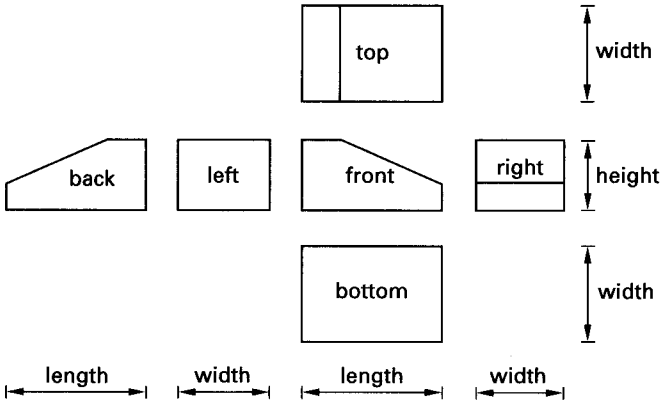

Figure 2.3 *Positions of Standard Orthographic Views*

It is common to refer to the front, side, and back views as *elevations* and to the top and bottom views as *plan views*. These terms are not absolute since any plane can be selected as the front.

5. AUXILIARY (ORTHOGRAPHIC) VIEWS

An *auxiliary view* is needed when an object has an inclined plane or curved feature or when there are more details than can be shown in the six principal views. As with the other orthographic views, the auxiliary view is a normal (face-on) view of the inclined plane.

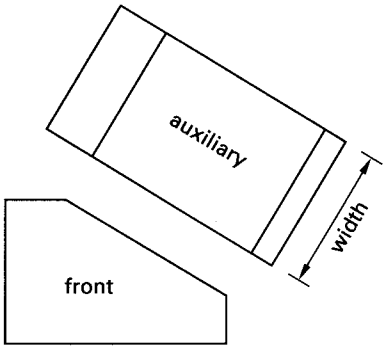

Figure 2.4 *Auxiliary View*

The projectors in an auxiliary view are perpendicular to only one of the directions in which a principal view is observed. Accordingly, only one of the three dimensions of width, height, and depth can be measured (scaled). In a *profile auxiliary view*, the object's width can be measured. In a *horizontal auxiliary view (auxiliary elevation)*, the object's height can be measured. In a *frontal auxiliary view*, the depth of the object can be measured.

6. OBLIQUE (ORTHOGRAPHIC) VIEWS

If the object is turned so that three principal planes are visible, it can be completely illustrated by a single *oblique view*.[4] In an oblique view, the direction from which the object is observed is not (necessarily) parallel to any of the directions from which principal and auxiliary views are observed.

In two common methods of oblique illustration, one of the view planes coincides with an orthographic view plane. Two of the drawing axes are at right angles to each other; one of these is vertical, and the other (the *oblique axis*) is oriented at 30° or 45° (originally chosen to coincide with standard drawing triangles). The ratio of scales used for the horizontal, vertical, and oblique axes can be 1:1:1 or 1:1:½. The latter ratio helps to overcome the visual distortion due to the absence of perspective in the oblique direction.

[4]Oblique views are not unique in this capability—perspective drawings share it. Oblique and perspective drawings are known as *pictorial drawings* because they give depth to the object by illustrating it in three dimensions.

Cavalier (45° oblique axis and 1:1:1 scale ratio) and *cabinet* (45° oblique axis and 1:1:1/2 scale ratio) *projections* are the two common types of oblique views that incorporate one of the orthographic views. If an angle of 9.5° is used (as in illustrating crystalline lattice structures), the technique is known as *clinographic projection.*

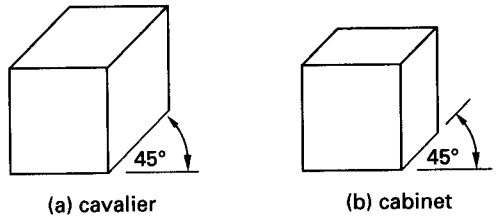

Figure 2.5 *Cavalier and Cabinet Oblique Drawings*

7. AXONOMETRIC (ORTHOGRAPHIC OBLIQUE) VIEWS

In axonometric views, the view plane is not parallel to any of the principal orthographic planes. Axonometric views and axonometric drawings are not the same. In a *view (projection)*, one or more of the face lengths is foreshortened. In a *drawing*, the lengths are drawn full length, resulting in a distorted illustration. Table 2.2 lists the proper ratios that should be observed.

Table 2.2 *Axonometric Foreshortening*

view	projector intersection angles	proper ratio of sides
isometric	120°, 120°, 120°	0.82:0.82:0.82
dimetric	131°25′, 131°25′, 97°10′	1:1:1/2
	103°38′, 103°38′, 152°44′	3/4:3/4:1
trimetric	102°28′, 144°16′, 113°16′	1:2/3:7/8
	138°14′, 114°46′, 107°	1:3/4:7/8

In an *isometric view*, the three projectors intersect at equal angles (120°) with the plane. This simplifies construction with standard 30° drawing triangles. All of the faces are foreshortened an equal amount, to $\sqrt{2/3}$, or approximately 81.6% of the true length. In a *dimetric view*, two of the projectors intersect at equal angles, and only two of the faces are equally reduced in length. In a *trimetric view*, all three intersection angles are different, and all three faces are reduced different amounts.

8. PERSPECTIVE VIEWS

In a *perspective view*, one or more sets of projectors converge to a fixed point known as the *center of vision.* In the *parallel perspective*, all vertical lines remain vertical in the picture; all horizontal frontal lines remain horizontal. Therefore, one face is parallel to the observer and only one set of projectors converges. In the *angular perspective*, two sets of projectors converge. In the little-used *oblique perspective*, all three sets of projectors converge.

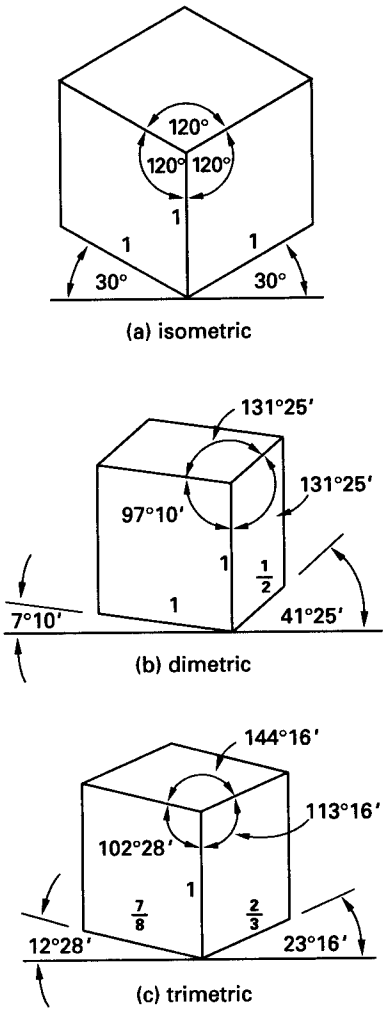

Figure 2.6 *Types of Axonometric Views*

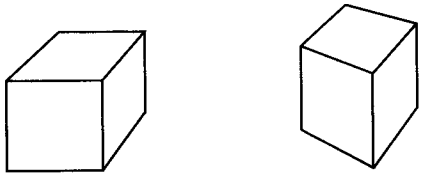

Figure 2.7 *Types of Perspective Views*

9. SECTIONS

The term *section* is an imaginary cut taken through an object to reveal the shape or interior construction.[5] Figure 2.8 illustrates the standard symbol for a *sectioning cut* and the resulting sectional view. Section arrows are perpendicular to the cutting plane and indicate the viewing direction.

[5]The term *section* is also used to mean a *cross section*—a slice of finite but negligible thickness that is taken from an object to show the cross section or interior construction at the plane of the slice.

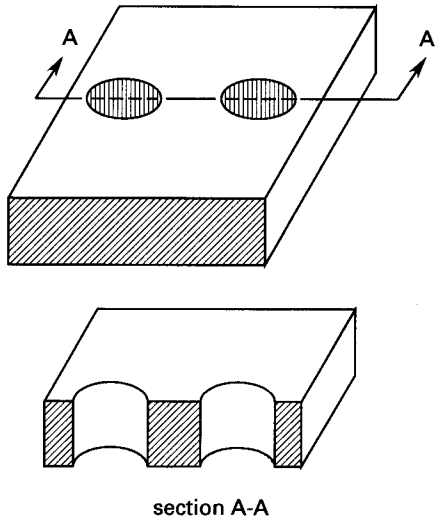

Figure 2.8 *Sectioning Cut Symbol and Sectional View*

10. TOLERANCES

The *tolerance* for a dimension is the total permissible variation or difference between the acceptable limits. The tolerance for a dimension can be specified in two ways: either as a general rule in the title block (e.g., ± 0.001 in unless otherwise specified) or as specific limits given with each dimension (e.g., 2.575 in ± 0.005 in).

11. SURFACE FINISH

Surface finish is specified by a combination of parameters.[6] The basic symbol for designating these factors is shown in Fig. 2.9. In the symbol, A is the maximum *roughness height index*, B is the optional minimum *roughness height*, C is the peak-to-valley *waviness height*, D is the optional peak-to-valley *waviness spacing (width)* rating, E is the optional *roughness width cutoff (roughness sampling length)*, F is the *lay*, and G is the *roughness width*. Unless minimums are specified, all parameters are maximum allowable values, and all lesser values are permitted.

Since the roughness varies, the waviness height is an arithmetic average within a sampled square, and the designation A is known as the *roughness weight*, R_a.[7] Values are normally given in micrometers (μm) or microinches (μin) in SI or customary U.S. units, respectively. A value for the roughness width cutoff of 0.80 mm (32 μin) is assumed when D is not specified. The lay symbol, F, can be = (parallel to indicated surface), ⊥ (perpendicular), C (circular), M (multidirectional), P (pitted), R (radial), or X (crosshatch).

If a small circle is placed at the A position, no machining is allowed and only cast, forged, die-cast, injection-molded, and other unfinished surfaces are acceptable.

[6]Specification does not indicate appearance (i.e., color, luster) or performance (i.e., hardness, corrosion resistance, microstructure).
[7]The symbol R_a is the same as the AA (arithmetic average) and CLA (centerline average) terms used in other (and earlier) standards.

Practice Problems 3-12

1. INTRODUCTION

Engineers working in design and analysis encounter mathematical problems on a daily basis. Although algebra and simple trigonometry are often sufficient for routine calculations, there are many instances when certain advanced subjects are needed. This chapter and the following ten, in addition to supporting the calculations used in other chapters, consolidate the mathematical concepts most often needed by engineers.

2. SYMBOLS USED IN THIS BOOK

Many symbols, letters, and Greek characters are used to represent variables in the formulas used throughout this book. These symbols and characters are defined in the nomenclature section of each chapter. However, some of the other symbols in this book are listed in Table 3.2.

3. GREEK ALPHABET

Table 3.1 *The Greek Alphabet*

A	α	alpha	N	ν	nu
B	β	beta	Ξ	ξ	xi
Γ	γ	gamma	O	o	omicron
Δ	δ	delta	Π	π	pi
E	ϵ	epsilon	P	ρ	rho
Z	ζ	zeta	Σ	σ	sigma
H	η	eta	T	τ	tau
Θ	θ	theta	Υ	υ	upsilon
I	ι	iota	Φ	ϕ	phi
K	κ	kappa	X	χ	chi
Λ	λ	lambda	Ψ	ψ	psi
M	μ	mu	Ω	ω	omega

4. TYPES OF NUMBERS

The *numbering system* consists of three types of numbers: real, imaginary, and complex. *Real numbers*, in turn, consist of rational numbers and irrational numbers. *Rational real numbers* are numbers that can be written as the ratio of two integers (e.g., 4, $^2/_5$, and $^1/_3$).[1] *Irrational real numbers* are nonterminating, nonrepeating numbers that cannot be expressed as the ratio of two integers (e.g., π and $\sqrt{2}$). Real numbers can be positive or negative.

Imaginary numbers are square roots of negative numbers. The symbols i and j are both used to represent the square root of -1.[2] For example, $\sqrt{-5} = \sqrt{5}\sqrt{-1} = \sqrt{5}i$. *Complex numbers* consist of combinations of real and imaginary numbers (e.g., $3 - 7i$).

5. SIGNIFICANT DIGITS

The significant digits in a number include the leftmost, nonzero digits to the rightmost digit written. Final answers from computations should be rounded off to the number of decimal places justified by the data. The answer can be no more accurate than the least accurate number in the data. Of course, rounding should be done on final calculation results only. It should not be done on interim results.

[1] Notice that 0.3333333 is a nonterminating number, but as it can be expressed as a ratio of two integers (i.e., $^1/_3$), it is a rational number.

[2] The symbol j is used to represent the square root of -1 in electrical calculations to avoid confusion with the current variable, i.

Table 3.2 *Symbols Used in This Book*

symbol	name	use	example
$\sum$	sigma	series summation	$\sum_{i=1}^{3} x_i = x_1 + x_2 + x_3$
π	pi	3.1415927...	$p = \pi D$
e	base of natural logs	2.71828...	
$\prod$	pi	series multiplication	$\prod_{i=1}^{3} x_i = x_1 x_2 x_3$
Δ	delta	change in quantity	$\Delta h = h_2 - h_1$
–	over bar	average value	$\overline{x}$
·	over dot	per unit time	$\dot{m} =$ mass flowing per second
!	factorial[a]		$x! = x(x-1)(x-2)\cdots(2)(1)$
| |	absolute value[b]		$\|-3\| = +3$
$\approx$	approximately equal to		$x \approx 1.5$
$\propto$	proportional to		$x \propto y$
∞	infinity		$x \rightarrow \infty$
log	base 10 logarithm		log(5.74)
ln	natural logarithm		ln(5.74)
exp	exponential power		$\exp(x) = e^x$
rms	root-mean-square	$\sqrt{\frac{1}{n}\sum_{i=1}^{n} x_i^2}$	V_{rms}
$\angle$	phasor or angle		$\angle 53°$

[a] *Zero factorial* (0!) is frequently encountered in the form of $(n-n)!$ when calculating permutations and combinations. Zero factorial is defined as 1.
[b] The notation abs (x) is also used to indicate the absolute value.

Table 3.3 *Examples of Significant Digits*

number as written	number of significant digits	implied range
341	3	340.5 to 341.5
34.1	3	34.05 to 34.15
0.00341	3	0.003405 to 0.003415
341×10^7	3	340.5×10^7 to 341.5×10^7
3.41×10^{-2}	3	3.405×10^{-2} to 3.415×10^{-2}
3410	4	3409.5 to 3410.5
341.0	4	340.95 to 341.05

There are two ways that significant digits can affect calculations. For the operations of multiplication and division, the final answer is rounded to the number of significant digits in the least significant multiplicand, divisor, or dividend. So, $2.0 \times 13.2 = 26$ since the first multiplicand (2.0) has two significant digits only.

For the operations of addition and subtraction, the final answer is rounded to the position of the least significant digit in the addenda, minuend, or subtrahend. So, $2.0 + 13.2 = 15.2$ because both addenda are significant to the tenth's position; but $2 + 13.4 = 15$ since the 2 is significant only in the ones' position.

The multiplication rule should not be used for addition or subtraction, as this can result in strange answers. For example, it would be incorrect to round $1700 + 0.1$ to 2000 simply because 0.1 has only one significant digit.

6. EQUATIONS

An *equation* is a mathematical statement of equality, such as $5 = 3 + 2$. *Algebraic equations* are written in terms of *variables*. In the equation $y = x^2 + 3$, the value of variable y depends on the value of variable x. Therefore, y is the *dependent variable* and x is the *independent variable*. The dependency of y on x is clearer when the equation is written in *functional form*: $y = f(x)$.

A *parametric equation* uses one or more independent variables (*parameters*) to describe a function.[3] For example, the parameter θ can be used to write the parametric equations of a unit circle.

$$x = \cos\theta \qquad 3.1$$

$$y = \sin\theta \qquad 3.2$$

[3] As used in this section, there is no difference between a parameter and an independent variable. However, the term *parameter* is also used as a descriptive measurement that determines or characterizes the form, size, or content of a function. For example, the radius is a parameter of a circle, and mean and variance are parameters of a probability distribution. Once these parameters are specified, the function is completely defined.

A unit circle can also be described by a *nonparametric equation.*[4]

$$x^2 + y^2 = 1 \qquad 3.3$$

7. FUNDAMENTAL ALGEBRAIC LAWS

Algebra provides the rules that allow complex mathematical relationships to be expanded or condensed. Algebraic laws may be applied to complex numbers, variables, and real numbers. The general rules for changing the form of a mathematical relationship are given as follows.

- commutative law for addition:

$$A + B = B + A \qquad 3.4$$

- commutative law for multiplication:

$$AB = BA \qquad 3.5$$

- associative law for addition:

$$A + (B + C) = (A + B) + C \qquad 3.6$$

- associative law for multiplication:

$$A(BC) = (AB)C \qquad 3.7$$

- distributive law:

$$A(B + C) = AB + AC \qquad 3.8$$

8. POLYNOMIALS

A *polynomial* is a rational expression—usually the sum of several variable terms known as *monomials*—that does not involve division. The *degree of the polynomial* is the highest power to which a variable in the expression is raised. The following *standard polynomial forms* are useful when trying to find the roots of an equation.

$$(a + b)(a - b) = a^2 - b^2 \qquad 3.9$$

$$(a \pm b)^2 = a^2 \pm 2ab + b^2 \qquad 3.10$$

$$(a \pm b)^3 = a^3 \pm 3a^2b + 3ab^2 \pm b^3 \qquad 3.11$$

$$(a^3 \pm b^3) = (a \pm b)(a^2 \mp ab + b^2) \qquad 3.12$$

$$(a^n - b^n) = (a - b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \cdots + b^{n-1}) \quad [n \text{ is any positive integer}] \qquad 3.13$$

$$(a^n + b^n) = (a + b)(a^{n-1} - a^{n-2}b + a^{n-3}b^2 - \cdots + b^{n-1}) \quad [n \text{ is any positive odd integer}] \qquad 3.14$$

The *binomial theorem* defines a polynomial of the form $(a + b)^n$.

$$(a + b)^n = \underset{[i=0]}{a^n} + \underset{[i=1]}{na^{n-1}b} + \underset{[i=2]}{C_2a^{n-2}b^2} + \cdots + C_ia^{n-i}b^i + \cdots + nab^{n-1} + b^n \qquad 3.15$$

$$C_i = \frac{n!}{i!(n-i)!} \qquad [\text{i} = 0,1,2,\ldots n] \qquad 3.16$$

[4]Since only the coordinate variables are used, this equation is also said to be in *Cartesian equation form.*

The coefficients of the expansion can be determined quickly from *Pascal's triangle*, Fig. 3.1. Notice that each entry is the sum of the two entries directly above it.

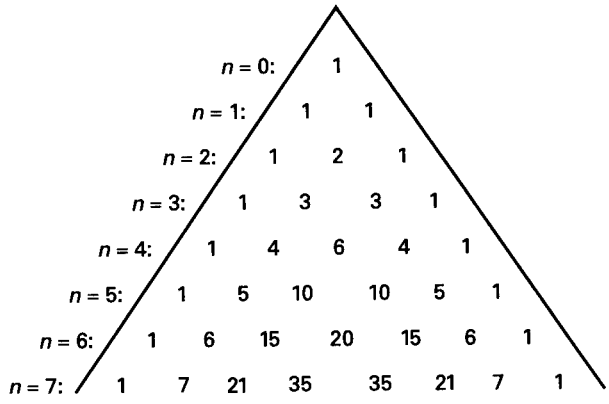

Figure 3.1 *Pascal's Triangle*

The values $r_1, r_2, \ldots, r_n$ of the independent variable x that satisfy a polynomial equation $f(x) = 0$ are known as *roots* or *zeros* of the polynomial. A polynomial of degree n with real coefficients will have at most n real roots, although they need not all be distinctly different.

9. ROOTS OF QUADRATIC EQUATIONS

A *quadratic equation* is an equation of the general form $ax^2 + bx + c = 0$ $[a \neq 0]$. The *roots*, x_1 and x_2, of the equation are the two values of x that satisfy it.

$$x_1, x_2 = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \qquad 3.17$$

$$x_1 + x_2 = -\frac{b}{a} \qquad 3.18$$

$$x_1x_2 = \frac{c}{a} \qquad 3.19$$

The types of roots of the equation can be determined from the *discriminant* (i.e., the quantity under the radical in Eq. 3.17).

- If $(b^2 - 4ac) > 0$, the roots are real and unequal.
- If $(b^2 - 4ac) = 0$, the roots are real and equal. This is known as a *double root.*
- If $(b^2 - 4ac) < 0$, the roots are complex and unequal.

10. ROOTS OF GENERAL POLYNOMIALS

It is more difficult to find roots of cubic and higher-degree polynomials because few general techniques exist.

- *inspection*: Finding roots by inspection is equivalent to making reasonable guesses about the roots and substituting into the polynomial.

- *graphing*: If the value of a polynomial $f(x)$ is calculated and plotted for different values of x, an approximate value of a root can be determined as the value of x at which the plot crosses the x-axis.
- *numerical methods*: If an approximate value of a root is known, numerical methods (bisection method, Newton's method, etc.) can be used to refine the value. The more efficient techniques are too complex to be performed by hand.
- *factoring*: If at least one root (say, $x = r$) of a polynomial $f(x)$ is known, the quantity $(x - r)$ can be factored out of $f(x)$ by long division. The resulting quotient will be lower by one degree, and the remaining roots may be easier to determine. This method is particularly applicable if the polynomial is in one of the standard forms presented in Sec. 8.
- *special cases*: Certain polynomial forms can be simplified by substitution or solved by standard formulas if they are recognized as being special cases. (The standard solution to the quadratic equation is such a special case.) For example, $ax^4 + bx^2 + c = 0$ can be reduced to a polynomial of degree 2 if the substitution $u = x^2$ is made.

11. EXTRANEOUS ROOTS

With simple equalities, it may appear possible to derive roots by basic algebraic manipulations.[5] However, multiplying each side of an equality by a power of a variable may introduce *extraneous roots*. Such roots do not satisfy the original equation even though they are derived according to the rules of algebra. Checking a calculated root is always a good idea, but is particularly necessary if the equation has been multiplied by one of its own variables.

Example 3.1

Use algebraic operations to determine a value that satisfies the following equation. Determine if the value is a valid or extraneous root.

$$\sqrt{x-2} = \sqrt{x} + 2$$

Solution

Square both sides.

$$x - 2 = x + 4\sqrt{x} + 4$$

Subtract x from each side, and combine the constants.

$$4\sqrt{x} = -6$$

Solve for x.

$$x = \left(\frac{-6}{4}\right)^2 = \frac{9}{4}$$

Substitute $x = 9/4$ into the original equation.

$$\sqrt{\frac{9}{4} - 2} = \sqrt{\frac{9}{4}} + 2$$
$$\frac{1}{2} = \frac{7}{2}$$

Since the equality is not established, $x = 9/4$ is an extraneous root.

12. DESCARTES' RULE OF SIGNS

Descartes' rule of signs determines the maximum number of positive (and negative) real roots that a polynomial will have by counting the number of sign reversals (i.e., changes in sign from one term to the next) in the polynomial. The polynomial $f(x)$ must have real coefficients and must be arranged in terms of descending powers of x.

- The number of positive roots of the polynomial equation $f(x) = 0$ will not exceed the number of sign reversals.
- The difference between the number of sign reversals and the number of positive roots is an even number.
- The number of negative roots of the polynomial equation $f(x) = 0$ will not exceed the number of sign reversals in the polynomial $f(-x)$.
- The difference between the number of sign reversals in $f(-x)$ and the number of negative roots is an even number.

Example 3.2

Determine the possible numbers of positive and negative roots that satisfy the following polynomial equation.

$$4x^5 - 5x^4 + 3x^3 - 8x^2 - 2x + 3 = 0$$

Solution

There are four sign reversals, so up to four positive roots exist. To keep the difference between the number of positive roots and the number of sign reversals an even number, the number of positive real roots is limited to zero, two, and four.

Substituting $-x$ for x in the polynomial results in

$$-4x^5 - 5x^4 - 3x^3 - 8x^2 + 2x + 3 = 0$$

There is only one sign reversal, so the number of negative roots cannot exceed one. There must be exactly one negative real root in order to keep the difference to an even number (zero in this case).

[5] In this sentence, *equality* means a combination of two expressions containing an equal sign. Any two expressions can be linked in this manner, even those that are not actually equal. For example, the expressions for two non-intersecting ellipses can be equated even though there is no intersection point. Finding extraneous roots is more likely when the underlying equality is false to begin with.

13. RULES FOR EXPONENTS AND RADICALS

In the expression $b^n = a$, b is known as the *base* and n is the *exponent* or *power*. In Eqs. 3.20 through 3.33, a, b, m, and n are any real numbers with limitations listed.

$$b^0 = 1 \qquad [b \neq 0] \qquad 3.20$$

$$b^1 = b \qquad 3.21$$

$$b^{-n} = \frac{1}{b^n} = \left(\frac{1}{b}\right)^n \qquad [b \neq 0] \qquad 3.22$$

$$\left(\frac{a}{b}\right)^n = \frac{a^n}{b^n} \qquad [b \neq 0] \qquad 3.23$$

$$(ab)^n = a^n b^n \qquad 3.24$$

$$b^{\frac{m}{n}} = \sqrt[n]{b^m} = \left(\sqrt[n]{b}\right)^m \qquad 3.25$$

$$(b^n)^m = b^{nm} \qquad 3.26$$

$$b^m b^n = b^{m+n} \qquad 3.27$$

$$\frac{b^m}{b^n} = b^{m-n} \qquad [b \neq 0] \qquad 3.28$$

$$\sqrt[n]{b} = b^{\frac{1}{n}} \qquad 3.29$$

$$\left(\sqrt[n]{b}\right)^n = \left(b^{\frac{1}{n}}\right)^n = b \qquad 3.30$$

$$\sqrt[n]{ab} = \sqrt[n]{a}\sqrt[n]{b} = a^{\frac{1}{n}} b^{\frac{1}{n}} = (ab)^{\frac{1}{n}} \qquad 3.31$$

$$\sqrt[n]{\frac{a}{b}} = \frac{\sqrt[n]{a}}{\sqrt[n]{b}} = \left(\frac{a}{b}\right)^{\frac{1}{n}} \qquad [b \neq 0] \qquad 3.32$$

$$\sqrt[m]{\sqrt[n]{b}} = \sqrt[mn]{b} = b^{\frac{1}{mn}} \qquad 3.33$$

14. LOGARITHMS

Logarithms can be considered to be exponents. For example, the exponent n in the expression $b^n = a$ is the logarithm of a to the base b. Therefore, the two expressions $\log_b a = n$ and $b^n = a$ are equivalent.

The base for *common logs* is 10. Usually, "log" will be written when common logs are desired, although "$\log_{10}$" appears occasionally. The base for *natural (Napierian) logs* is 2.71828..., a number which is given the symbol e. When natural logs are desired, usually "ln" will be written, although "$\log_e$" is also used.

Most logarithms will contain an integer part (the *characteristic*) and a decimal part (the *mantissa*). The logarithm of any number less than one is negative. If the number is greater than one, its logarithm is positive. Although the logarithm may be negative, the mantissa is always positive. For negative logarithms, the characteristic is found by expressing the logarithm as the sum of a negative characteristic and a positive mantissa.

For common logarithms of numbers greater than one, the characteristics will be positive and equal to one less than the number of digits in front of the decimal. If the number is less than one, the characteristic will be negative and equal to one more than the number of zeros immediately following the decimal point.

If a negative logarithm is to be used in a calculation, it must first be converted to *operational form* by adding the characteristic and mantissa. The operational form should be used in all calculations and is the form displayed by scientific calculators.

The logarithm of a negative number is a complex number.

Example 3.3

Use logarithm tables to determine the operational form of $\log_{10}(0.05)$.

Solution

Since the number is less than one and there is one leading zero, the characteristic is found by observation to be -2. From a book of logarithm tables, the mantissa of 5.0 is 0.699. Two ways of combining the mantissa and characteristic are possible.

method 1: $\overline{2}.699$

method 2: $8.699 - 10$

The operational form of this logarithm is $-2 + 0.699 = -1.301$.

15. LOGARITHM IDENTITIES

Prior to the widespread availability of calculating devices, logarithm identities were used to solve complex calculations by reducing the solution method to table look-up, addition, and subtraction. Logarithm identities are still useful in simplifying expressions containing exponentials and other logarithms. In Eqs. 3.34 through 3.45, $a \neq 1$, $b \neq 1$, $x > 0$, and $y > 0$.

$$\log_b(b) = 1 \qquad 3.34$$

$$\log_b(1) = 0 \qquad 3.35$$

$$\log_b(b^n) = n \qquad 3.36$$

$$\log(x^a) = a \log(x) \qquad 3.37$$

$$\log\left(\sqrt[n]{x}\right) = \log\left(x^{\frac{1}{n}}\right) = \frac{\log(x)}{n} \qquad 3.38$$

$$b^{n \log_b(x)} = x^n = \text{antilog}[n \log_b(x)] \qquad 3.39$$

$$b^{\frac{\log_b(x)}{n}} = x^{\frac{1}{n}} \qquad 3.40$$

$$\log(xy) = \log(x) + \log(y) \qquad 3.41$$

$$\log\left(\frac{x}{y}\right) = \log(x) - \log(y) \qquad 3.42$$

$$\log_a(x) = \log_b(x) \log_a(b) \qquad 3.43$$

$$\ln(x) = \log_{10}(x) \ln(10) \approx 2.3026 \log_{10}(x) \qquad 3.44$$

$$\log_{10}(x) = \ln(x) \log_{10}(e) \approx 0.4343 \ln(x) \qquad 3.45$$

Example 3.4

The surviving fraction, x, of a radioactive isotope is given by $x = e^{-0.005t}$. For what value of t will the surviving percentage be 7%?

Solution

$$x = 0.07 = e^{-0.005t}$$

Take the natural log of both sides.

$$\ln(0.07) = \ln\left(e^{-0.005t}\right)$$

From 3.36, $\ln e^x = x$. Therefore,

$$-2.66 = -0.005t$$

$$t = 532$$

16. PARTIAL FRACTIONS

The method of *partial fractions* is used to transform a proper polynomial fraction of two polynomials into a sum of simpler expressions, a procedure known as *resolution*.[6,7] The technique can be considered to be the act of "unadding" a sum to obtain all of the addends.

Suppose $H(x)$ is a proper polynomial fraction of the form $P(x)/Q(x)$. The object of the resolution is to determine the partial fractions u_1/v_1, u_2/v_2, etc., such that

$$H(x) = \frac{P(x)}{Q(x)} = \frac{u_1}{v_1} + \frac{u_2}{v_2} + \frac{u_3}{v_3} + \cdots \qquad 3.46$$

The form of the denominator polynomial $Q(x)$ will be the main factor in determining the form of the partial fractions. The task of finding the u_i and v_i is simplified by categorizing the possible forms of $Q(x)$.

case 1: $Q(x)$ factors into n different linear terms.

$$Q(x) = (x - a_1)(x - a_2)\cdots(x - a_n) \qquad 3.47$$

Then,

$$H(x) = \sum_{i=1}^{n} \frac{A_i}{x - a_i} \qquad 3.48$$

case 2: $Q(x)$ factors into n identical linear terms.

$$Q(x) = (x - a)(x - a)\cdots(x - a) \qquad 3.49$$

Then,

$$H(x) = \sum_{i=1}^{n} \frac{A_i}{(x - a)^i} \qquad 3.50$$

case 3: $Q(x)$ factors into n different quadratic terms, $x^2 + p_i x + q_i$. Then,

$$H(x) = \sum_{i=1}^{n} \frac{A_i x + B_i}{x^2 + p_i x + q_i} \qquad 3.51$$

case 4: $Q(x)$ factors into n identical quadratic terms, $x^2 + px + q$. Then,

$$H(x) = \sum_{i=1}^{n} \frac{A_i x + B_i}{(x^2 + px + q)^i} \qquad 3.52$$

Once the general forms of the partial fractions have been determined from inspection, the *method of undetermined coefficients* is used. The partial fractions are all cross-multiplied to obtain $Q(x)$ as the denominator, and the coefficients are found by equating $P(x)$ and the cross-multiplied numerator.

Example 3.5

Resolve $H(x)$ into partial fractions.

$$H(x) = \frac{x^2 + 2x + 3}{x^4 + x^3 + 2x^2}$$

Solution

Here, $Q(x) = x^4 + x^3 + 2x^2$, which factors into $x^2(x^2 + x + 2)$. This is a combination of cases 2 and 3.

$$H(x) = \frac{A_1}{x} + \frac{A_2}{x^2} + \frac{A_3 + A_4 x}{x^2 + x + 2}$$

Cross-multiplying to obtain a common denominator yields

$$\frac{(A_1 + A_4)x^3 + (A_1 + A_2 + A_3)x^2 + (2A_1 + A_2)x + 2A_2}{x^4 + x^3 + 2x^2}$$

Since the original numerator is known, the following simultaneous equations result.

$$\begin{aligned} A_1 + A_4 &= 0 \\ A_1 + A_2 + A_3 &= 1 \\ 2A_1 + A_2 &= 2 \\ 2A_2 &= 3 \end{aligned}$$

The solutions are $A_1 = 0.25$, $A_2 = 1.5$, $A_3 = -0.75$, and $A_4 = -0.25$.

$$H(x) = \frac{1}{4x} + \frac{3}{2x^2} - \frac{x + 3}{(4)(x^2 + x + 2)}$$

[6] To be a *proper polynomial fraction*, the degree of the numerator must be less than the degree of the denominator. If the polynomial fraction is improper, the denominator can be divided into the numerator to obtain whole and fractional polynomials. The method of partial fractions can then be used to reduce the fractional polynomial.

[7] This technique is particularly useful for calculating integrals and inverse Laplace transforms in subsequent chapters.

17. SIMULTANEOUS LINEAR EQUATIONS

A *linear equation* with n variables is a polynomial of degree 1 describing a geometric shape in n-space. A *homogeneous linear equation* is one that has no constant term, and a *nonhomogeneous linear equation* has a constant term.

A solution to a set of simultaneous linear equations represents the intersection point of the geometric shapes in n-space. For example, if the equations are limited to two variables (e.g., $y = 4x - 5$), they describe straight lines. The solution to two simultaneous linear equations in 2-space is the point where the two lines intersect. The set of the two equations is said to be a *consistent system* when there is such an intersection.[8]

Simultaneous equations do not always have unique solutions, and some have none at all. In addition to crossing in 2-space, lines can be parallel or they can be the same line expressed in a different equation format (i.e., dependent equations). In some cases, parallelism and dependency can be determined by inspection. In most cases, however, matrix and other advanced methods must be used to determine whether a solution exists. A set of linear equations with no simultaneous solution is known as an *inconsistent system.*

Several methods exist for solving linear equations simultaneously by hand.[9]

- *graphing*: The equations are plotted and the intersection point is read from the graph. This method is possible only with two-dimensional problems.
- *substitution*: An equation is rearranged so that one variable is expressed as a combination of the other variables. The expression is then substituted into the remaining equations wherever the selected variable appears.
- *reduction*: All terms in the equations are multiplied by constants chosen to eliminate one or more variables when the equations are added or subtracted. The remaining sum can then be solved for the other variables. This method is also known as *eliminating the unknowns.*
- *Cramer's rule*: This method is covered in Chap. 4.

Example 3.6

Solve the following set of linear equations by (a) substitution and (b) reduction.

$$2x + 3y = 12 \qquad \text{[Eq. 1]}$$
$$3x + 4y = 8 \qquad \text{[Eq. 2]}$$

Solution

(a) From Eq. 1, solve for variable x.

$$x = 6 - 1.5y \qquad \text{[Eq. 3]}$$

Substitute $6 - 1.5y$ into Eq. 2 wherever x appears.

$$(3)(6 - 1.5y) + 4y = 8$$
$$18 - 4.5y + 4y = 8$$
$$y = 20$$

Substitute 20 for y in Eq. 3.

$$x = 6 - (1.5)(20) = -24$$

The solution $(-24, 20)$ should be checked to verify that it satisfies both original equations.

(b) Eliminate variable x by multiplying Eq. 1 by 3 and Eq. 2 by 2.

$$3 \times \text{Eq. 1: } 6x + 9y = 36 \qquad \text{[Eq. 1']}$$
$$2 \times \text{Eq. 2: } 6x + 8y = 16 \qquad \text{[Eq. 2']}$$

Subtract Eq. 2′ from Eq. 1′.

$$y = 20 \quad \text{[Eq. 1'} - \text{Eq. 2']}$$

Substitute $y = 20$ into Eq. 1′.

$$6x + (9)(20) = 36$$
$$x = -24$$

The solution $(-24, 20)$ should be checked to verify that it satisfies both original equations.

18. COMPLEX NUMBERS

A *complex number*, **Z**, is a combination of real and imaginary numbers. When expressed as a sum (e.g., $a + bi$), the complex number is said to be in *rectangular* or *trigonometric form.* The complex number can be plotted on the real-imaginary coordinate system known as the *complex plane*, as illustrated in Fig. 3.2.

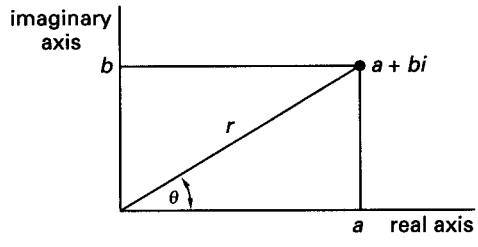

Figure 3.2 *A Complex Number in the Complex Plane*

[8] A homogeneous system always has at least one solution: the *trivial solution*, in which all variables have a value of zero.
[9] Other methods exist, but they require a computer.

The complex number $\mathbf{Z} = a + bi$ can also be expressed in *exponential form.*[10] The quantity r is known as the *modulus* of $\mathbf{Z}$; θ is the *argument.*

$$a + bi = re^{i\theta} \quad 3.53$$

$$r = \text{mod}(\mathbf{Z}) = \sqrt{a^2 + b^2} \quad 3.54$$

$$\theta = \arg(\mathbf{Z}) = \arctan\left(\frac{b}{a}\right) \quad 3.55$$

Similarly, the *phasor form* (also known as the *polar form*) is

$$\mathbf{Z} = r\angle\theta \quad 3.56$$

The *rectangular form* can be determined from r and θ.

$$a = r\cos\theta \quad 3.57$$

$$b = r\sin\theta \quad 3.58$$

$$\mathbf{Z} = a + bi = r\cos\theta + ir\sin\theta = r(\cos\theta + i\sin\theta) \quad 3.59$$

The *cis form* is a shorthand method of writing a complex number in rectangular (trigonometric) form.

$$a + bi = r(\cos\theta + i\sin\theta) = r\,\text{cis}\,\theta \quad 3.60$$

Euler's equation (Eq. 61) expresses the equality of complex numbers in exponential and trigonometric form.

$$e^{i\theta} = \cos\theta + i\sin\theta \quad 3.61$$

Related expressions are

$$e^{-i\theta} = \cos\theta - i\sin\theta \quad 3.62$$

$$\cos\theta = \frac{e^{i\theta} + e^{-i\theta}}{2} \quad 3.63$$

$$\sin\theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} \quad 3.64$$

Example 3.7

What is the exponential form of the complex number $\mathbf{Z} = 3 + 4i$?

Solution

$$r = \sqrt{a^2 + b^2} = \sqrt{3^2 + 4^2} = \sqrt{25} = 5$$

$$\theta = \arctan\left(\frac{b}{a}\right) = \arctan\left(\frac{4}{3}\right) = 0.927 \text{ rad}$$

$$\mathbf{Z} = re^{i\theta} = 5e^{i(0.927)}$$

19. OPERATIONS ON COMPLEX NUMBERS

Most algebraic operations (addition, multiplication, exponentiation, etc.) work with complex numbers, but notable exceptions are the inequality operators. The concept of one complex number being less than or greater than another complex number is meaningless.

[10]The terms *polar form*, *phasor form*, and *exponential form* are all used somewhat interchangeably.

When adding two complex numbers, real parts are added to real parts, and imaginary parts are added to imaginary parts.

$$(a_1 + ib_1) + (a_2 + ib_2) = (a_1 + a_2) + i(b_1 + b_2) \quad 3.65$$

$$(a_1 + ib_1) - (a_2 + ib_2) = (a_1 - a_2) + i(b_1 - b_2) \quad 3.66$$

Multiplication of two complex numbers in rectangular form is accomplished by the use of the algebraic distributive law, remembering that $i^2 = -1$.

Division of complex numbers in rectangular form requires use of the *complex conjugate.* The complex conjugate of the complex number $(a+bi)$ is $(a-bi)$. By multiplying the numerator and the denominator by the complex conjugate, the denominator will be converted to the real number $a^2 + b^2$. This technique is known as *rationalizing* the denominator and is illustrated in Ex. 3.8(c).

Multiplication and division are often more convenient when the complex numbers are in exponential or phasor forms, as Eqs. 3.67 and 3.68 show.

$$(r_1e^{i\theta_1})(r_2e^{i\theta_2}) = r_1r_2e^{i(\theta_1+\theta_2)} \quad 3.67$$

$$\frac{r_1e^{i\theta_1}}{r_2e^{i\theta_2}} = \left(\frac{r_1}{r_2}\right)e^{i(\theta_1-\theta_2)} \quad 3.68$$

Taking powers and roots of complex numbers requires *de Moivre's theorem*, Eqs. 3.69 and 3.70.

$$\mathbf{Z}^n = (re^{i\theta})^n = r^ne^{in\theta} \quad 3.69$$

$$\sqrt[n]{\mathbf{Z}} = (re^{i\theta})^{\frac{1}{n}} = \sqrt[n]{r}e^{i\left(\frac{\theta+k(360)}{n}\right)} \quad [k = 0, 1, 2, \ldots n-1] \quad 3.70$$

Example 3.8

Perform the following complex arithmetic.

(a) $(3 + 4i) + (2 + i)$

(b) $(7 + 2i)(5 - 3i)$

(c) $\dfrac{2 + 3i}{4 - 5i}$

Solution

(a) $$(3 + 4i) + (2 + i) = (3 + 2) + (4 + 1)i = 5 + 5i$$

(b) $$\begin{aligned}(7 + 2i)(5 - 3i) &= (7)(5) - (7)(3i) + (2i)(5) - (2i)(3i) \\ &= 35 - 21i + 10i - 6i^2 \\ &= 35 - 21i + 10i - (6)(-1) \\ &= 41 - 11i\end{aligned}$$

(c) Multiply the numerator and denominator by the complex conjugate of the denominator.

$$\frac{2+3i}{4-5i} = \frac{(2+3i)(4+5i)}{(4-5i)(4+5i)}$$
$$= \frac{-7+22i}{(4)^2+(5)^2}$$
$$= \left(\frac{-7}{41}\right) + i\left(\frac{22}{41}\right)$$

20. LIMITS

A *limit* (*limiting value*) is the value a function approaches when an independent variable approaches a target value. For example, suppose the value of $y = x^2$ is desired as x approaches 5. This could be written as

$$\lim_{x \to 5} x^2 \qquad 3.71$$

The power of limit theory is wasted on simple calculations such as this but is appreciated when the function is undefined at the target value. The object of limit theory is to determine the limit without having to evaluate the function at the target. The general case of a limit evaluated as x approaches the target value a is written as

$$\lim_{x \to a} f(x) \qquad 3.72$$

It is not necessary for the actual value $f(a)$ to exist for the limit to be calculated. The function $f(x)$ may be undefined at point a. However, it is necessary that $f(x)$ be defined on both sides of point a for the limit to exist. If $f(x)$ is undefined on one side, or if $f(x)$ is discontinuous at $x = a$ (as in Fig. 3.3(c) and 3.3(d)), the limit does not exist.

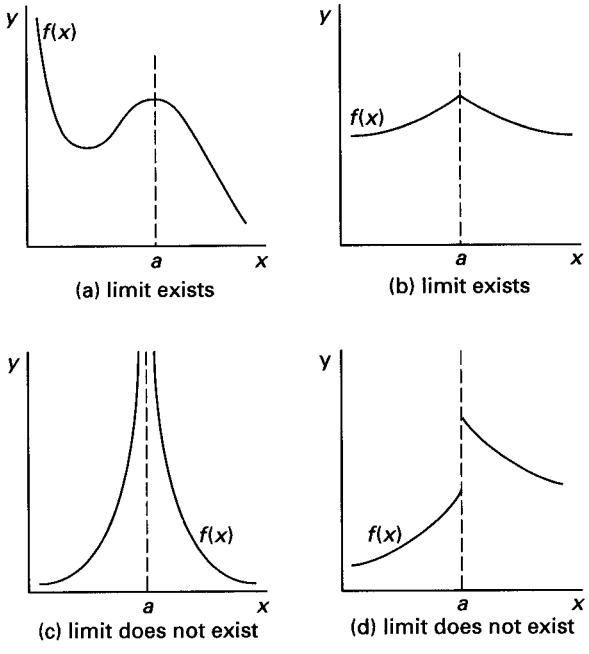

Figure 3.3 *Existence of Limits*

The following theorems can be used to simplify expressions when calculating limits.

$$\lim_{x \to a} x = a \qquad 3.73$$

$$\lim_{x \to a} (mx + b) = ma + b \qquad 3.74$$

$$\lim_{x \to a} b = b \qquad 3.75$$

$$\lim_{x \to a} (kF(x)) = k \lim_{x \to a} F(x) \qquad 3.76$$

$$\lim_{x \to a} \left(F_1(x) \left\{ \begin{matrix} + \\ - \\ \times \\ \div \end{matrix} \right\} F_2(x) \right)$$
$$= \lim_{x \to a} (F_1(x)) \left\{ \begin{matrix} + \\ - \\ \times \\ \div \end{matrix} \right\} \lim_{x \to a} (F_2(x)) \qquad 3.77$$

The following identities can be used to simplify limits of trigonometric expressions.

$$\lim_{x \to 0} \sin x = 0 \qquad 3.78$$

$$\lim_{x \to 0} \left(\frac{\sin x}{x}\right) = 1 \qquad 3.79$$

$$\lim_{x \to 0} \cos x = 1 \qquad 3.80$$

The following standard methods (tricks) can be used to determine limits.

- If the limit is taken to infinity, all terms can be divided by the largest power of x in the expression. This will leave at least one constant. Any quantity divided by a power of x vanishes as x approaches infinity.
- If the expression is a quotient of two expressions, any common factors should be eliminated from the numerator and denominator.
- *L'Hôpital's rule*, Eq. 3.81, should be used when the numerator and denominator of the expression both approach zero or both approach infinity.[11] $P^k(x)$ and $Q^k(x)$ are the kth derivatives of the functions $P(x)$ and $Q(x)$, respectively.[12] (L'Hôpital's rule can be applied repeatedly as required.)

$$\lim_{x \to a} \left(\frac{P(x)}{Q(x)}\right) = \lim_{x \to a} \left(\frac{P^k(x)}{Q^k(x)}\right) \qquad 3.81$$

[11] L'Hôpital's rule should not be used when only the denominator approaches zero. In that case, the limit approaches infinity regardless of the numerator.

[12] The calculation of derivatives is covered in Chap. 8.

Example 3.9

Evaluate the following limits.

(a) $\lim_{x\to 3}\left(\frac{x^3-27}{x^2-9}\right)$

(b) $\lim_{x\to\infty}\left(\frac{3x-2}{4x+3}\right)$

(c) $\lim_{x\to 2}\left(\frac{x^2+x-6}{x^2-3x+2}\right)$

Solution

(a) Factor the numerator and denominator. (L'Hôpital's rule can also be used.)

$$\lim_{x\to 3}\left(\frac{x^3-27}{x^2-9}\right)=\lim_{x\to 3}\left(\frac{(x-3)(x^2+3x+9)}{(x-3)(x+3)}\right)$$
$$=\lim_{x\to 3}\left(\frac{x^2+3x+9}{x+3}\right)=\frac{(3)^2+(3)(3)+9}{3+3}$$
$$=\frac{9}{2}$$

(b) Divide through by the largest power of x. (L'Hôpital's rule can also be used.)

$$\lim_{x\to\infty}\left(\frac{3x-2}{4x+3}\right)=\lim_{x\to\infty}\left(\frac{3-\frac{2}{x}}{4+\frac{3}{x}}\right)$$
$$=\frac{3-\frac{2}{\infty}}{4+\frac{3}{\infty}}$$
$$=\frac{3-0}{4+0}=\frac{3}{4}$$

(c) Use L'Hôpital's rule. (Factoring can also be used.) Take the first derivative of the numerator and denominator.

$$\lim_{x\to 2}\left(\frac{x^2+x-6}{x^2-3x+2}\right)=\lim_{x\to 2}\left(\frac{2x+1}{2x-3}\right)$$
$$=\frac{(2)(2)+1}{(2)(2)-3}$$
$$=\frac{5}{1}=5$$

21. SEQUENCES AND PROGRESSIONS

A *sequence* is an ordered *progression* of numbers, a_i, such as $1, 4, 9, 16, 25, \ldots$ The *terms* in a sequence can be all positive, all negative, or of alternating signs. a_n is known as the *general term* of the sequence.

$$\{A\} = \{a_1, a_2, a_3, \ldots a_n\} \qquad 3.82$$

A sequence is said to *diverge* (i.e., be *divergent*) if the terms approach infinity or if the terms fail to approach any finite value, and is said to *converge* (i.e., be *convergent*) if the terms approach any finite value (including zero). That is, the sequence converges if the limit defined by Eq. 3.83 exists.

$$\lim_{n\to\infty} a_n \begin{cases} \text{converges if } L \text{ is finite} \\ \text{diverges if } L \text{ is infinite} \\ \text{or does not exist} \end{cases} \qquad 3.83$$

The main task associated with a sequence is determining the next (or the general) term. If several terms of a sequence are known, the next (unknown) term must usually be found by intuitively determining the pattern of the sequence. In some cases, though, the method of *Rth-order differences* can be used to determine the next term. This method consists of subtracting each term from the following term to obtain a set of differences. If the differences are not all equal, the next order of differences can be calculated.

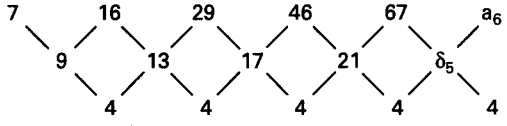
Example 3.10

What is the general term of the sequence A?

$$\{A\} = \left\{3, \frac{9}{2}, \frac{27}{6}, \frac{81}{24}, \ldots\right\}$$

Solution

The solution is purely intuitive. The numerator is recognized as a power series based on the number 3. The denominator is recognized as the factorial sequence. The general term is



$$a_n = \frac{3^n}{n!}$$

Example 3.11

Find the sixth term in the sequence $\{7, 16, 29, 46, 67, a_6\}$.

Solution

The sixth term is not intuitively obvious, so the method of Rth-order differences is tried. The pattern is not obvious from the first order differences, but the second order differences are all 4.

$$\delta_5 - 21 = 4$$
$$\delta_5 = 25$$
$$a_6 - 67 = \delta_5 = 25$$
$$a_6 = 92$$

Example 3.12

Does the sequence with general term e^n/n converge or diverge?

Solution

See if the limit exists.

$$\lim_{n\to\infty}\left(\frac{e^n}{n}\right) = \frac{\infty}{\infty}$$

Since ∞/∞ is inconclusive, apply L'Hôpital's rule. Take the derivative of both the numerator and the denominator with respect to n.

$$\lim_{n\to\infty}\left(\frac{e^n}{1}\right) = \frac{\infty}{1}$$
$$= \infty$$

The sequence diverges.

22. STANDARD SEQUENCES

There are four standard sequences: the geometric, arithmetic, harmonic, and p-sequences.

- *geometric sequence*: The geometric sequence converges for $-1 < r \leq 1$ and diverges otherwise. a is known as the *first term*; r is known as the *common ratio*.

$$a_n = ar^{n-1} \qquad \begin{bmatrix} a \text{ is a constant} \\ n = 1, 2, 3, \ldots, \infty \end{bmatrix} \qquad 3.84$$

example: $\{1, 2, 4, 8, 16, 32\}$ $(a = 1, r = 2)$

- *arithmetic sequence*: The arithmetic sequence always diverges.

$$a_n = a + (n-1)d \qquad \begin{bmatrix} a \text{ and } d \text{ are constants} \\ n = 1, 2, 3, \ldots, \infty \end{bmatrix} \qquad 3.85$$

example: $\{2, 7, 12, 17, 22, 27\}$ $(a = 2, d = 5)$

- *harmonic sequence*: The harmonic sequence always converges.

$$a_n = \frac{1}{n} \qquad [n = 1, 2, 3, \ldots, \infty] \qquad 3.86$$

example: $\{1, 1/2, 1/3, 1/4, 1/5, 1/6\}$

- *p-sequence*: The p-sequence converges if $p \geq 0$ and diverges if $p < 0$. (Notice that this is different than the p-series.)

$$a_n = \frac{1}{n^p} \qquad [n = 1, 2, 3, \ldots, \infty] \qquad 3.87$$

example: $\{1, 1/4, 1/9, 1/16, 1/25, 1/36\}$ $(p = 2)$

23. SERIES

A *series* is the sum of terms in a sequence. There are two types of series. A *finite series* has a finite number of terms, and an *infinite series* has an infinite number of terms.[13] The main tasks associated with series are determining the sum of the terms and whether the series converges. A series is said to *converge* (be *convergent*) if the sum, S_n, of its term exists.[14] A finite series is always convergent.

The performance of a series based on standard sequences (defined in Sec. 22) is well known.

- *geometric series*:

$$S_n = \sum_{i=1}^{n} ar^{i-1} = \frac{a(1-r^n)}{1-r} \qquad \text{[finite]} \qquad 3.88$$

$$S_n = \sum_{i=1}^{\infty} ar^{i-1} = \frac{a}{1-r} \qquad \begin{bmatrix} \text{infinite} \\ -1 < r < 1 \end{bmatrix} \qquad 3.89$$

- *arithmetic series*: The infinite series diverges unless $a = d = 0$.

$$S_n = \sum_{i=1}^{n}(a + (i-1)d) = \frac{n(2a + (n-1)d)}{2} \qquad \text{[finite]} \qquad 3.90$$

- *harmonic series*: The infinite series converges.
- *p-series*: The infinite series diverges if $p \leq 1$. The infinite series converges if $p > 1$. (Notice that this is different than the p-sequence.)

24. TESTS FOR SERIES CONVERGENCE

It is obvious that all *finite series* (i.e., series having a finite number of terms) converge. That is, the sum, S_n, defined by Eq. 3.91 exists.

$$S_n = \sum_{i=1}^{n} a_i \qquad 3.91$$

Convergence of an infinite series can be determined by taking the limit of the sum. If the limit exists, the series converges; otherwise, it diverges.

$$\lim_{n\to\infty} S_n = \lim_{n\to\infty} \sum_{i=1}^{n} a_i \qquad 3.92$$

In most cases, the expression for the general term a_n will be known, but there will be no simple expression for the sum S_n. Therefore, Eq. 3.92 cannot be used to determine convergence. It is helpful, but not conclusive, to look at the limit of the general term. If L, as

[13] The term *infinite series* does not imply the sum is infinite.

[14] This is different from the definition of convergence for a sequence where only the last term was evaluated.

defined in Eq. 3.93, is nonzero, the series diverges. If L equals zero, the series may either converge or diverge. Additional testing is needed in that case.

$$\lim_{n\to\infty} a_n \begin{cases} = 0 & \text{inconclusive} \\ \neq 0 & \text{diverges} \end{cases} \qquad 3.93$$

Two tests can be used independently or after Eq. 3.93 has proven inconclusive: the ratio and comparison tests. The *ratio test* calculates the limit of the ratio of two consecutive terms.

$$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} \begin{cases} < 1 & \text{converges} \\ = 1 & \text{inconclusive} \\ > 1 & \text{diverges} \end{cases} \qquad 3.94$$

The *comparison test* is an indirect method of determining convergence of an unknown series. It compares a standard series (geometric and p-series are commonly used) against the unknown series. If all terms in a positive standard series are smaller than the terms in the unknown series and the standard series diverges, the unknown series must also diverge. Similarly, if all terms in the standard series are larger than the terms in the unknown series and the standard series converges, then the unknown series also converges.

In mathematical terms, if A and B are both series of positive terms such that $a_n < b_n$ for all values of n, then (a) B diverges if A diverges, and (b) A converges if B converges.

Example 3.13

Does the infinite series A converge or diverge?

$$A = 3 + \frac{9}{2} + \frac{27}{6} + \frac{81}{24} + \cdots$$

Solution

The general term was found in Ex. 3.9 to be

$$a_n = \frac{3^n}{n!}$$

Since limits of factorials are not easily determined, use the ratio test.

$$\lim_{n\to\infty}\left(\frac{a_{n+1}}{a_n}\right) = \lim_{n\to\infty}\left(\frac{\frac{3^{n+1}}{(n+1)!}}{\frac{3^n}{n!}}\right) = \lim_{n\to\infty}\left(\frac{3}{n+1}\right)$$
$$= \frac{3}{\infty} = 0$$

Since the limit is less than 1, the infinite series converges.

Example 3.14

Does the infinite series A converge or diverge?

$$A = 2 + \frac{3}{4} + \frac{4}{9} + \frac{5}{16} + \cdots$$

Solution

By observation, the general term is

$$a_n = \frac{1+n}{n^2}$$

The general term can be expanded by partial fractions to

$$a_n = \frac{1}{n} + \frac{1}{n^2}$$

However, $1/n$ is the harmonic series. Since the harmonic series is divergent and this series is larger than the harmonic series (by the term $1/n^2$), this series also diverges.

25. SERIES OF ALTERNATING SIGNS[15]

Some series contain both positive and negative terms. The ratio and comparison tests can both be used to determine if a series with alternating signs converges. If a series containing all positive terms converges, then the same series with some negative terms also converges. Therefore, the all-positive series should be tested for convergence. If the all-positive series converges, the original series is said to be *absolutely convergent*. (If the all-positive series diverges and the original series converges, the original series is said to be *conditionally convergent.*)

Alternatively, the ratio test can be used with the absolute value of the ratio. The same criteria apply.

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| \begin{cases} < 1 & \text{converges} \\ = 1 & \text{inconclusive} \\ > 1 & \text{diverges} \end{cases} \qquad 3.95$$

PRACTICE PROBLEMS

Series

1. Calculate the following sum.

$$\sum_{j=1}^{5}[(j+1)^2 - 1]$$

(A) 15
(B) 24
(C) 35
(D) 85

The answer is (D).

Logarithms

2. If every 0.1 sec a quantity increases by 0.1% of its current value, calculate the doubling time.

(A) 14 sec
(B) 70 sec
(C) 690 sec
(D) 69,000 sec

The answer is (B).

[15]This terminology is commonly used even though it is not necessary that the signs strictly alternate.

Practice Problems 4-8

1. MATRICES

A *matrix* is an ordered set of *entries* (*elements*) arranged rectangularly and set off by brackets.[1] The entries can be variables or numbers. A matrix by itself has no particular value—it is merely a convenient method of representing a set of numbers.

The size of a matrix is given by the number of rows and columns, and the nomenclature $m \times n$ is used for a matrix with m rows and n columns. For a *square matrix*, the number of rows and columns will be the same, a quantity known as the *order* of the matrix.

Bold uppercase letters are used to represent matrices, while lowercase letters represent the entries. For example, a_{23} would be the entry in the second row and third column of matrix $\mathbf{A}$.

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

A *submatrix* is the matrix that remains when selected rows or columns are removed from the original matrix.[2] For example, for matrix $\mathbf{A}$, the submatrix remaining after the second row and second column have been removed is

$$\begin{bmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{bmatrix}$$

An *augmented matrix* results when the original matrix is extended by repeating one or more of its rows or columns or by adding rows and columns from another matrix. For example, for the matrix $\mathbf{A}$, the augmented matrix created by repeating the first and second columns is

$$\left[\begin{array}{ccc|cc} a_{11} & a_{12} & a_{13} & a_{11} & a_{12} \\ a_{21} & a_{22} & a_{23} & a_{21} & a_{22} \\ a_{31} & a_{32} & a_{33} & a_{31} & a_{32} \end{array}\right]$$

2. SPECIAL TYPES OF MATRICES

Certain types of matrices are given special designations.

- *cofactor matrix*: the matrix that is formed when every entry is replaced by the cofactor (see Sec. 4) of that entry
- *column matrix*: a matrix with only one column
- *complex matrix*: a matrix with complex number entries
- *diagonal matrix*: a square matrix with all zero entries except for the a_{ij} for which $i = j$
- *echelon matrix*: a matrix in which the number of zeros preceding the first nonzero entry of a row increases row by row until only zero rows remain. A *row-reduced echelon matrix* is an echelon matrix in which the first nonzero entry in each row is a 1 and all other entries in the columns are zero.
- *identity matrix*: a diagonal (square) matrix with all nonzero entries equal to 1, usually designated as $\mathbf{I}$, having the property that $\mathbf{AI} = \mathbf{IA} = \mathbf{A}$
- *null matrix*: the same as a zero matrix
- *row matrix*: a matrix with only one row
- *scalar matrix*:[3] a diagonal (square) matrix with all diagonal entries equal to some scalar k
- *singular matrix*: a matrix whose determinant is zero (see Sec. 10)

[1] The term *array* is synonymous with *matrix*, although the former is more likely to be used in computer applications.

[2] By definition, a matrix is a submatrix of itself.

[3] Although the term *complex matrix* means a matrix with complex entries, the term *scalar matrix* means more than a matrix with scalar entries.

- *skew symmetric matrix*: a square matrix whose transpose (see Sec. 9) is equal to the negative of itself (i.e., $\mathbf{A} = -\mathbf{A}^t$)
- *square matrix*: a matrix with the same number of rows and columns (i.e., $m = n$)
- *symmetric(al) matrix*: a square matrix whose transpose is equal to itself (i.e., $\mathbf{A}^t = \mathbf{A}$), which occurs only when $a_{ij} = a_{ji}$
- *triangular matrix*: a square matrix with zeros in all positions above or below the diagonal
- *unit matrix*: the same as the identity matrix
- *zero matrix*: a matrix with all zero entries

$$\begin{bmatrix} 9 & 0 & 0 & 0 \\ 0 & -6 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 5 \end{bmatrix}$$
(a) diagonal

$$\begin{bmatrix} 2 & 18 & 2 & 18 \\ 0 & 0 & 1 & 9 \\ 0 & 0 & 0 & 9 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$
(b) echelon

$$\begin{bmatrix} 1 & 9 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$
(c) row-reduced echelon

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$
(d) identity

$$\begin{bmatrix} 2 & 0 & 0 & 0 \\ 7 & 6 & 0 & 0 \\ 9 & 1 & 1 & 0 \\ 8 & 0 & 4 & 5 \end{bmatrix}$$
(e) triangular

$$\begin{bmatrix} 3 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 \\ 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}$$
(f) scalar

Figure 4.1 *Examples of Special Matrices*

3. ROW EQUIVALENT MATRICES

A matrix **B** is said to be *row equivalent* to a matrix **A** if it is obtained by a finite sequence of *elementary row operations* on **A**:

- interchanging the ith and jth rows
- multiplying the ith row by a nonzero scalar
- replacing the ith row by the sum of the original ith row and k times the jth row

However, two matrices that are row equivalent as defined do not have the same determinants. (See Sec. 5.)

Gauss-Jordan elimination is the process of using these elementary row operations to row-reduce a matrix to echelon or row-reduced echelon forms, as illustrated in Ex. 4.8. When a matrix has been converted to a row-reduced echelon matrix, it is said to be in *row canonical form*. Thus, the terms *row-reduced echelon form* and *row canonical form* are synonymous.

4. MINORS AND COFACTORS

Minors and cofactors are determinants of submatrices associated with particular entries in the original square matrix. The *minor* of entry a_{ij} is the determinant of a submatrix resulting from the elimination of the single row i and the single column j. For example, the minor corresponding to entry a_{12} in a 3×3 matrix **A** is the determinant of the matrix created by eliminating row 1 and column 2.

$$\text{minor of } a_{12} = \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} \qquad 4.1$$

The *cofactor* of entry a_{ij} is the minor of a_{ij} multiplied by either $+1$ or -1, depending on the position of the entry. (That is, the cofactor either exactly equals the minor or it differs only in sign.) The sign is determined according to the following positional matrix.[4]

$$\begin{bmatrix} +1 & -1 & +1 & \dots \\ -1 & +1 & -1 & \dots \\ +1 & -1 & +1 & \dots \\ \vdots & \vdots & \vdots & \end{bmatrix}$$

For example, the cofactor of entry a_{12} in matrix **A** (described in Sec. 4) is

$$\text{cofactor of } a_{12} = -\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} \qquad 4.2$$

Example 4.1

What is the cofactor corresponding to the -3 entry in the following matrix?

$$\mathbf{A} = \begin{bmatrix} 2 & 9 & 1 \\ -3 & 4 & 0 \\ 7 & 5 & 9 \end{bmatrix}$$

Solution

The minor's submatrix is created by eliminating the row and column of the -3 entry.

$$\mathbf{M} = \begin{bmatrix} 9 & 1 \\ 5 & 9 \end{bmatrix}$$

The minor is the determinant of **M**.

$$|\mathbf{M}| = (9)(9) - (5)(1) = 76$$

The sign corresponding to the -3 position is negative. Therefore, the cofactor is -76.

[4]The sign of the cofactor a_{ij} is positive if $(i + j)$ is even and is negative if $(i + j)$ is odd.

5. DETERMINANTS

A *determinant* is a scalar calculated from a square matrix. The determinant of matrix **A** can be represented as $D\{\mathbf{A}\}$, Det (**A**), $\Delta\mathbf{A}$, or $|\mathbf{A}|$.[5] The following rules can be used to simplify the calculation of determinants.

- If **A** has a row or column of zeros, the determinant is zero.
- If **A** has two identical rows or columns, the determinant is zero.
- If **B** is obtained from **A** by adding a multiple of a row (column) to another row (column) in **A**, then $|\mathbf{B}| = |\mathbf{A}|$.
- If **A** is triangular, the determinant is equal to the product of the diagonal entries.
- If **B** is obtained from **A** by multiplying one row or column in **A** by a scalar k, then $|\mathbf{B}| = k|\mathbf{A}|$.
- If **B** is obtained from the $n \times n$ matrix **A** by multiplying by the scalar matrix k, then $|k\mathbf{A}| = k^n|\mathbf{A}|$.
- If **B** is obtained from **A** by switching two rows or columns in **A**, then $|\mathbf{B}| = -|\mathbf{A}|$.

Calculation of determinants is laborious for all but the smallest or simplest of matrices. For a 2×2 matrix, the formula used to calculate the determinant is easy to remember.

$$\mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$|\mathbf{A}| = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc \qquad 4.3$$

Two methods are commonly used for calculating the determinant of 3×3 matrices by hand. The first uses an augmented matrix constructed from the original matrix and the first two columns (as presented in Sec. 1).[6] The determinant is calculated as the sum of the products in the left-to-right downward diagonals less the sum of the products in the left-to-right upward diagonals.

$$\mathbf{A} = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

augmented **A** =

$$\begin{array}{cccccc} + & + & + & - & - & - \\ \begin{bmatrix} a & b & c & a & b \\ d & e & f & d & e \\ g & h & i & g & h \end{bmatrix} \end{array} \qquad 4.4$$

$$|\mathbf{A}| = aei + bfg + cdh - gec - hfa - idb \qquad 4.5$$

[5]The vertical bars should not be confused with the square brackets used to set off a matrix, nor with absolute value.

[6]It is not actually necessary to construct the augmented matrix, but doing so helps avoid errors.

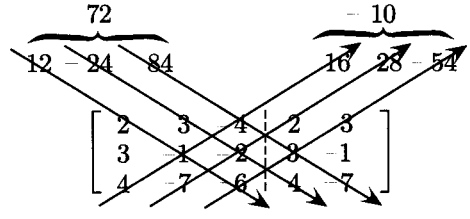
The second method of calculating the determinant is somewhat slower than the first for a 3×3 matrix but illustrates the method that must be used to calculate determinants of 4×4 and larger matrices. This method is known as *expansion by cofactors*. One row (column) is selected as the base row (column). The selection is arbitrary, but the number of calculations required to obtain the determinant can be minimized by choosing the row (column) with the most zeros. The determinant is equal to the sum of the products of the entries in the base row (column) and their corresponding cofactors.

$$\mathbf{A} = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

$$|\mathbf{A}| = a\begin{vmatrix} e & f \\ h & i \end{vmatrix} - d\begin{vmatrix} b & c \\ h & i \end{vmatrix} + g\begin{vmatrix} b & c \\ e & f \end{vmatrix} \qquad 4.6$$

Example 4.2

Calculate the determinant of matrix **A** (a) by cofactor expansion, and (b) by the augmented matrix method.



$$\mathbf{A} = \begin{bmatrix} 2 & 3 & -4 \\ 3 & -1 & -2 \\ 4 & -7 & -6 \end{bmatrix}$$

Solution

(a) Since there are no zero entries, it does not matter which row or column is chosen as the base. Choose the first column as the base.

$$\begin{aligned} |\mathbf{A}| &= 2\begin{vmatrix} -1 & -2 \\ -7 & -6 \end{vmatrix} - 3\begin{vmatrix} 3 & -4 \\ -7 & -6 \end{vmatrix} + 4\begin{vmatrix} 3 & -4 \\ -1 & -2 \end{vmatrix} \\ &= (2)(6-14) - (3)(-18-28) + (4)(-6-4) \\ &= 82 \end{aligned}$$

(b)

$$|\mathbf{A}| = 72 - (-10) = 82$$

6. MATRIX ALGEBRA[7]

Matrix algebra differs somewhat from standard algebra.

- *equality*: Two matrices, **A** and **B**, are equal only if they have the same numbers of rows and columns *and* if all corresponding entries are equal.
- *inequality*: The $>$ and $<$ operators are not used in matrix algebra.

[7]Since matrices are used to simplify the presentation and solution of sets of linear equations, matrix algebra is also known as *linear algebra*.

- *commutative law of addition*:

$$\mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A} \qquad 4.7$$

- *associative law of addition*:

$$\mathbf{A} + (\mathbf{B} + \mathbf{C}) = (\mathbf{A} + \mathbf{B}) + \mathbf{C} \qquad 4.8$$

- *associative law of multiplication*:

$$(\mathbf{AB})\mathbf{C} = \mathbf{A}(\mathbf{BC}) \qquad 4.9$$

- *left distributive law*:

$$\mathbf{A}(\mathbf{B} + \mathbf{C}) = \mathbf{AB} + \mathbf{AC} \qquad 4.10$$

- *right distributive law*:

$$(\mathbf{B} + \mathbf{C})\mathbf{A} = \mathbf{BA} + \mathbf{CA} \qquad 4.11$$

- *scalar multiplication*:

$$k(\mathbf{AB}) = (k\mathbf{A})\mathbf{B} = \mathbf{A}(k\mathbf{B}) \qquad 4.12$$

It is important to recognize that, except for trivial and special cases, matrix multiplication is not commutative. That is,

$$\mathbf{AB} \neq \mathbf{BA}$$

7. MATRIX ADDITION AND SUBTRACTION

Addition and subtraction of two matrices is possible only if both matrices have the same numbers of rows and columns (i.e., order). They are accomplished by adding or subtracting the corresponding entries of the two matrices.

8. MATRIX MULTIPLICATION

A matrix can be multiplied by a scalar, an operation known as *scalar multiplication*, in which case all entries of the matrix are multiplied by that scalar. For example, for the 2×2 matrix $\mathbf{A}$,

$$k\mathbf{A} = \begin{bmatrix} ka_{11} & ka_{12} \\ ka_{21} & ka_{22} \end{bmatrix}$$

A matrix can be multiplied by another matrix, but only if the left-hand matrix has the same number of columns as the right-hand matrix has rows. *Matrix multiplication* occurs by multiplying the elements in each left-hand matrix row by the entries in each right-hand matrix column, adding the products, and placing the sum at the intersection point of the participating row and column.

Matrix division can only be accomplished by multiplying by the inverse of the denominator matrix. There is no specific division operation in matrix algebra.

Example 4.3

Determine the product matrix $\mathbf{C}$.

$$\mathbf{C} = \begin{bmatrix} 1 & 4 & 3 \\ 5 & 2 & 6 \end{bmatrix} \begin{bmatrix} 7 & 12 \\ 11 & 8 \\ 9 & 10 \end{bmatrix}$$

Solution

The left-hand matrix has three columns, and the right-hand matrix has three rows. Therefore, the two matrices can be multiplied.

The first row of the left-hand matrix and the first column of the right-hand matrix are worked with first. The corresponding entries are multiplied and the products are summed.

$$c_{11} = (1)(7) + (4)(11) + (3)(9) = 78$$

The intersection of the top row and left column is the entry in the upper left-hand corner of the matrix $\mathbf{C}$.

The remaining entries are calculated similarly.

$$c_{12} = (1)(12) + (4)(8) + (3)(10) = 74$$
$$c_{21} = (5)(7) + (2)(11) + (6)(9) = 111$$
$$c_{22} = (5)(12) + (2)(8) + (6)(10) = 136$$

The product matrix is

$$\mathbf{C} = \begin{bmatrix} 78 & 74 \\ 111 & 136 \end{bmatrix}$$

9. TRANSPOSE

The *transpose*, $\mathbf{A}^t$, of an $m \times n$ matrix $\mathbf{A}$ is an $n \times m$ matrix constructed by taking the ith row and making it the ith column. The diagonal is unchanged. For example,

$$\mathbf{A} = \begin{bmatrix} 1 & 6 & 9 \\ 2 & 3 & 4 \\ 7 & 1 & 5 \end{bmatrix}$$

$$\mathbf{A}^t = \begin{bmatrix} 1 & 2 & 7 \\ 6 & 3 & 1 \\ 9 & 4 & 5 \end{bmatrix}$$

Transpose operations have the following characteristics.

$$(\mathbf{A}^t)^t = \mathbf{A} \qquad 4.13$$
$$(k\mathbf{A})^t = k(\mathbf{A}^t) \qquad 4.14$$
$$\mathbf{I}^t = \mathbf{I} \qquad 4.15$$
$$(\mathbf{AB})^t = \mathbf{B}^t\mathbf{A}^t \qquad 4.16$$
$$(\mathbf{A} + \mathbf{B})^t = \mathbf{A}^t + \mathbf{B}^t \qquad 4.17$$
$$|\mathbf{A}^t| = |\mathbf{A}| \qquad 4.18$$

10. SINGULARITY AND RANK

A *singular matrix* is one whose determinant is zero. Similarly, a *nonsingular* matrix is one whose determinant is nonzero.

The *rank* of a matrix is the maximum number of linearly independent row or column vectors.[8] A matrix has rank r if it has at least one nonsingular square submatrix of order r but has no nonsingular square submatrix of order more than r. While the submatrix must be square (in order to calculate the determinant), the original matrix need not be.

The rank of an $m \times n$ matrix will be, at most, the smaller of m and n. The rank of a null matrix is zero. The ranks of a matrix and its transpose are the same. If a matrix is in echelon form, the rank will be equal to the number of rows containing at least one nonzero entry. For a 3×3 matrix, the rank can either be 3 (if it is nonsingular), 2 (if any one of its 2×2 submatrices is nonsingular), 1 (if it and all 2×2 submatrices are singular), or 0 (if it is null).

The determination of rank is laborious if done by hand. Either the matrix is reduced to echelon form by using elementary row operations, or exhaustive enumeration is used to create the submatrices and many determinants are calculated. If a matrix has more rows than columns and row-reduction is used, the work required to put the matrix in echelon form can be reduced by working with the transpose of the original matrix.

Example 4.4

What is the rank of matrix $\mathbf{A}$?

$$\mathbf{A} = \begin{bmatrix} 1 & -2 & -1 \\ -3 & 3 & 0 \\ 2 & 2 & 4 \end{bmatrix}$$

Solution

Matrix $\mathbf{A}$ is singular because $|\mathbf{A}| = 0$. However, there is at least one 2×2 nonsingular submatrix:

$$\begin{vmatrix} 1 & -2 \\ -3 & 3 \end{vmatrix} = (1)(3) - (-3)(-2) = -3$$

Therefore, the rank is 2.

Example 4.5

Determine the rank of matrix $\mathbf{A}$ by reducing it to echelon form.

$$\mathbf{A} = \begin{bmatrix} 7 & 4 & 9 & 1 \\ 0 & 2 & -5 & 3 \\ 0 & 4 & -10 & 6 \end{bmatrix}$$

Solution

By inspection, the matrix can be row-reduced by subtracting two times the second row from the third row. The matrix cannot be further reduced. Since there are two nonzero rows, the rank is 2.

$$\begin{bmatrix} 7 & 4 & 9 & 1 \\ 0 & 2 & -5 & 3 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

11. CLASSICAL ADJOINT

The *classical adjoint* is the transpose of the cofactor matrix. The resulting matrix can be designated as $\mathbf{A}_{\text{adj}}$, $\text{adj}\{\mathbf{A}\}$ or $\mathbf{A}^{\text{adj}}$.

Example 4.6

What is the classical adjoint of matrix $\mathbf{A}$?

$$\mathbf{A} = \begin{bmatrix} 2 & 3 & -4 \\ 0 & -4 & 2 \\ 1 & -1 & 5 \end{bmatrix}$$

Solution

The matrix of cofactors is

$$\begin{bmatrix} -18 & 2 & 4 \\ -11 & 14 & 5 \\ -10 & -4 & -8 \end{bmatrix}$$

The transpose of the matrix of cofactors is

$$\mathbf{A}_{\text{adj}} = \begin{bmatrix} -18 & -11 & -10 \\ 2 & 14 & -4 \\ 4 & 5 & -8 \end{bmatrix}$$

12. INVERSE

The product of a matrix $\mathbf{A}$ and its inverse, $\mathbf{A}^{-1}$, is the identity matrix, $\mathbf{I}$. Only square matrices have inverses, but not all square matrices are invertible. A matrix has an inverse if and only if it is nonsingular (i.e., its determinant is nonzero).

$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I} \qquad 4.19$$

$$(\mathbf{A}\mathbf{B})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1} \qquad 4.20$$

The inverse of a 2×2 matrix is easily determined by formula.

$$\mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$\mathbf{A}^{-1} = \frac{\begin{bmatrix} d & -b \\ -c & a \end{bmatrix}}{|\mathbf{A}|} \qquad 4.21$$

[8] The *row rank* and *column rank* are the same.

For a 3×3 or larger matrix, the inverse is determined by dividing every entry in the classical adjoint by the determinant of the original matrix.

$$\mathbf{A}^{-1} = \frac{\mathbf{A}_{\text{adj}}}{|\mathbf{A}|} \qquad 4.22$$

Example 4.7

What is the inverse of matrix $\mathbf{A}$?

$$\mathbf{A} = \begin{bmatrix} 4 & 5 \\ 2 & 3 \end{bmatrix}$$

Solution

The determinant is calculated as

$$|\mathbf{A}| = (4)(3) - (2)(5) = 2$$

Using Eq. 4.22, the inverse is

$$\mathbf{A}^{-1} = \frac{\begin{bmatrix} 3 & -5 \\ -2 & 4 \end{bmatrix}}{2} = \begin{bmatrix} \frac{3}{2} & -\frac{5}{2} \\ -1 & 2 \end{bmatrix}$$

Check.

$$\mathbf{A}\mathbf{A}^{-1} = \begin{bmatrix} 4 & 5 \\ 2 & 3 \end{bmatrix}\begin{bmatrix} \frac{3}{2} & -\frac{5}{2} \\ -1 & 2 \end{bmatrix} = \begin{bmatrix} 6-5 & -10+10 \\ 3-3 & -5+6 \end{bmatrix}$$
$$= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \mathbf{I} \qquad \text{[ok]}$$

13. WRITING SIMULTANEOUS LINEAR EQUATIONS IN MATRIX FORM

Matrices are used to simplify the presentation and solution of sets of simultaneous linear equations. For example, the following three methods of presenting simultaneous linear equations are equivalent:

$$a_{11}x_1 + a_{12}x_2 = b_1$$
$$a_{21}x_1 + a_{22}x_2 = b_2$$
$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$$
$$\mathbf{AX} = \mathbf{B}$$

In the second and third representations, $\mathbf{A}$ is known as the *coefficient matrix*, $\mathbf{X}$ as the *variable matrix*, and $\mathbf{B}$ as the *constant matrix*.

Not all systems of simultaneous equations have solutions, and those that do may not have unique solutions. The existence of a solution can be determined by calculating the determinant of the coefficient matrix. These rules are summarized in Table 4.1.

- If the system of linear equations is homogeneous (i.e., $\mathbf{B}$ is a zero matrix) and $|\mathbf{A}|$ is zero, there are an infinite number of solutions.
- If the system is homogeneous and $|\mathbf{A}|$ is nonzero, only the trivial solution exists.
- If the system of linear equations is nonhomogeneous (i.e., $\mathbf{B}$ is not a zero matrix) and $|\mathbf{A}|$ is nonzero, there is a unique solution to the set of simultaneous equations.
- If $|\mathbf{A}|$ is zero, a nonhomogeneous system of simultaneous equations may still have a solution. The requirement is that the determinants of all substitutional matrices (see Sec. 14) are zero, in which case there will be an infinite number of solutions. Otherwise, no solution exists.

Table 4.1 *Solution Existence Rules for Simultaneous Equations*

	$\mathbf{B} = 0$	$\mathbf{B} \neq 0$
$\lvert\mathbf{A}\rvert = 0$	infinite number of solutions (linearly dependent equations)	either an infinite number of solutions or no solution at all
$\lvert\mathbf{A}\rvert \neq 0$	trivial solution only ($x_i = 0$)	unique nonzero solution

14. SOLVING SIMULTANEOUS LINEAR EQUATIONS

Gauss-Jordan elimination can be used to obtain the solution to a set of simultaneous linear equations. The coefficient matrix is augmented by the constant matrix. Then, elementary row operations are used to reduce the coefficient matrix to canonical form. All of the operations performed on the coefficient matrix are performed on the constant matrix. The variable values that satisfy the simultaneous equations will be the entries in the constant matrix when the coefficient matrix is in canonical form.

Determinants are used to calculate the solution to linear simultaneous equations through a procedure known as *Cramer's rule.*

The procedure is to calculate determinants of the original coefficient matrix $\mathbf{A}$ and of the n matrices resulting from the systematic replacement of a column in $\mathbf{A}$ by the constant matrix $\mathbf{B}$. For a system of three equations in three unknowns, there are three substitutional matrices, $\mathbf{A}_1$, $\mathbf{A}_2$, and $\mathbf{A}_3$, as well as the original coefficient matrix, for a total of four matrices whose determinants must be calculated.

The values of the unknowns that simultaneously satisfy all of the linear equations are

$$x_1 = \frac{|\mathbf{A}_1|}{|\mathbf{A}|} \qquad 4.23$$

$$x_2 = \frac{|\mathbf{A}_2|}{|\mathbf{A}|} \qquad 4.24$$

$$x_3 = \frac{|\mathbf{A}_3|}{|\mathbf{A}|} \qquad 4.25$$

Example 4.8

Use Gauss-Jordan elimination to solve the following system of simultaneous equations.

$$2x + 3y - 4z = 1$$
$$3x - y - 2z = 4$$
$$4x - 7y - 6z = -7$$

Solution

The augmented matrix is created by appending the constant matrix to the coefficient matrix.

$$\left[\begin{array}{ccc|c} 2 & 3 & -4 & 1 \\ 3 & -1 & -2 & 4 \\ 4 & -7 & -6 & -7 \end{array}\right]$$

Elementary row operations are used to reduce the coefficient matrix to canonical form. For example, two times the first row is subtracted from the third row. This step obtains the 0 needed in the a_{31} position.

$$\left[\begin{array}{ccc|c} 2 & 3 & -4 & 1 \\ 3 & -1 & -2 & 4 \\ 0 & -13 & 2 & -9 \end{array}\right]$$

This process continues until the following form is obtained.

$$\left[\begin{array}{ccc|c} 1 & 0 & 0 & 3 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 2 \end{array}\right]$$

$x = 3$, $y = 1$, and $z = 2$ satisfy this system of equations.

Example 4.9

Use Cramer's rule to solve the following system of simultaneous equations.

$$2x + 3y - 4z = 1$$
$$3x - y - 2z = 4$$
$$4x - 7y - 6z = -7$$

Solution

The determinant of the coefficient matrix is

$$|\mathbf{A}| = \begin{vmatrix} 2 & 3 & -4 \\ 3 & -1 & -2 \\ 4 & -7 & -6 \end{vmatrix} = 82$$

The determinants of the substitutional matrices are

$$|\mathbf{A}_1| = \begin{vmatrix} 1 & 3 & -4 \\ 4 & -1 & -2 \\ -7 & -7 & -6 \end{vmatrix} = 246$$

$$|\mathbf{A}_2| = \begin{vmatrix} 2 & 1 & -4 \\ 3 & 4 & -2 \\ 4 & -7 & -6 \end{vmatrix} = 82$$

$$|\mathbf{A}_3| = \begin{vmatrix} 2 & 3 & 1 \\ 3 & -1 & 4 \\ 4 & -7 & -7 \end{vmatrix} = 164$$

The values of x, y, and z that satisfy the linear equations are

$$x = \frac{246}{82} = 3$$

$$y = \frac{82}{82} = 1$$

$$z = \frac{164}{82} = 2$$

15. EIGENVALUES AND EIGENVECTORS

Eigenvalues and eigenvectors (also known as *characteristic values* and *characteristic vectors*) of a square matrix $\mathbf{A}$ are the scalars k and matrices $\mathbf{X}$ such that

$$\mathbf{AX} = k\mathbf{X} \qquad 4.26$$

The scalar k is an eigenvalue of $\mathbf{A}$ if and only if the matrix $(k\mathbf{I} - \mathbf{A})$ is singular; that is, if $|k\mathbf{I} - \mathbf{A}| = 0$. This equation is called the *characteristic equation* of the matrix $\mathbf{A}$. When expanded, the determinant is called the *characteristic polynomial*. The method of using the characteristic polynomial to find eigenvalues and eigenvectors is illustrated in Ex. 4.10.

If all of the eigenvalues are unique (i.e., nonrepeating), then Eq. 4.27 is valid.

$$[k\mathbf{I} - \mathbf{A}]\mathbf{X} = 0 \qquad 4.27$$

Example 4.10

Find the eigenvalues and nonzero eigenvectors of the matrix $\mathbf{A}$.

$$\mathbf{A} = \begin{bmatrix} 2 & 4 \\ 6 & 4 \end{bmatrix}$$

Solution

$$k\mathbf{I} - \mathbf{A} = \begin{bmatrix} k & 0 \\ 0 & k \end{bmatrix} - \begin{bmatrix} 2 & 4 \\ 6 & 4 \end{bmatrix} = \begin{bmatrix} k-2 & -4 \\ -6 & k-4 \end{bmatrix}$$

The characteristic polynomial is found by setting the determinant $|k\mathbf{I} - \mathbf{A}|$ equal to zero.

$$(k-2)(k-4) - (-6)(-4) = 0$$
$$k^2 - 6k - 16 = (k-8)(k+2) = 0$$

The roots of the characteristic polynomial are $k = +8$ and $k = -2$. These are the eigenvalues of $\mathbf{A}$.

Substituting $k = 8$,

$$k\mathbf{I} - \mathbf{A} = \begin{bmatrix} 8-2 & -4 \\ -6 & 8-4 \end{bmatrix} = \begin{bmatrix} 6 & -4 \\ -6 & 4 \end{bmatrix}$$

This can be interpreted as the linear equation $6x_1 - 4x_2 = 0$. The values of x that satisfy this equation define the eigenvector. An eigenvector $\mathbf{X}$ associated with the eigenvalue $+8$ is

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 4 \\ 6 \end{bmatrix}$$

All other eigenvectors for this eigenvalue are multiples of $\mathbf{X}$. Normally $\mathbf{X}$ is reduced to smallest integers.

$$\mathbf{X} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

Similarly, the eigenvector associated with the eigenvalue -2 is

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} +4 \\ -4 \end{bmatrix}$$

Reducing this to smallest integers gives

$$\mathbf{X} = \begin{bmatrix} +1 \\ -1 \end{bmatrix}$$

PRACTICE PROBLEMS

Determinants

1. What is the determinant of matrix $\mathbf{A}$?

$$\mathbf{A} = \begin{bmatrix} 8 & 2 & 0 & 0 \\ 2 & 8 & 2 & 0 \\ 0 & 2 & 8 & 2 \\ 0 & 0 & 2 & 4 \end{bmatrix}$$

(A) 459
(B) 832
(C) 1552
(D) 1776

The answer is (C).

Simultaneous Linear Equations

2. Use Cramer's rule to solve for the values of x, y, and z that simultaneously satisfy the following equations.

$$x + y = -4$$
$$x + z - 1 = 0$$
$$2z - y + 3x = 4$$

(A) $(x, y, z) = (3, 2, 1)$
(B) $(x, y, z) = (-3, -1, 2)$
(C) $(x, y, z) = (3, -1, -3)$
(D) $(x, y, z) = (-1, -3, 2)$

The answer is (D).

1. INTRODUCTION

A physical property or quantity can be a scalar, vector, or tensor. A *scalar* has only magnitude. Knowing its value is sufficient to define a scalar. Mass, enthalpy, density, and speed are examples of scalars.

Force, momentum, displacement, and velocity are examples of vectors. A *vector* is a directed straight line with a specific magnitude. Thus, a vector is specified completely by its direction (consisting of the vector's *angular orientation* and its *sense*) and magnitude. A vector's *point of application* (*terminal point*) is not needed to define the vector.[1] Two vectors with the same direction and magnitude are said to be *equal vectors* even though their *lines of action* may be different.[2]

A vector can be designated by a boldface variable (as in this book) or as a combination of the variable and some other symbol. For example, the notations $\mathbf{V}$, $\bar{V}$, $\hat{V}$, $\vec{V}$, and $\underline{V}$ are used by different authorities to represent vectors. The magnitude of a vector can be designated by either $|\mathbf{V}|$ or V (not bold).

Stress, dielectric constant, and magnetic susceptibility are examples of tensors. A *tensor* has magnitude in a specific direction but the direction is not unique. Tensors are frequently associated with *anisotropic materials* that have different properties in different directions. A tensor in three-dimensional space is defined by nine components, compared with the three that are required to define vectors. These components are written in matrix form. Stress, σ, at a point, for example, would be defined by the following tensor matrix.

$$\sigma = \begin{pmatrix} \sigma_{xx} & \sigma_{xy} & \sigma_{xz} \\ \sigma_{yx} & \sigma_{yy} & \sigma_{yz} \\ \sigma_{zx} & \sigma_{zy} & \sigma_{zz} \end{pmatrix}$$

2. VECTORS IN n-SPACE

In some cases, a vector, $\mathbf{V}$, will be designated by its two endpoints in n-dimensional vector space. A common example is three-dimensional force-space. Usually, one of the points will be the origin, in which case the vector is said to be "based at the origin," "origin-based," or "zero-based."[3] If one of the endpoints is the origin, specifying a terminal point P would represent a force directed from the origin to point P.

If a coordinate system is superimposed on the vector space, a vector can be specified in terms of the n coordinates of its two endpoints. The magnitude of the vector $\mathbf{V}$ is the distance in vector space between the two points, as given by Eq. 5.1. Similarly, the direction is defined by the angle the vector makes with one of the axes.

$$|\mathbf{V}| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \qquad 5.1$$

$$\phi = \arctan\left(\frac{y_2 - y_1}{x_2 - x_1}\right) \qquad 5.2$$

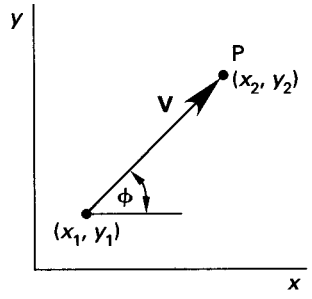

Figure 5.1 *Vector in Two-Dimensional Space*

[1] A vector that is constrained to act at or through a certain point is a *bound vector (fixed vector)*. A *sliding vector (transmissible vector)* can be applied anywhere along its line of action. A *free vector* is not constrained and can be applied at any point in space.

[2] A distinction is sometimes made between equal vectors and equivalent vectors. *Equivalent vectors* produce the same effect but are not necessarily equal.

[3] Any vector directed from P_1 to P_2 can be transformed into a zero-based vector by subtracting the coordinates of point P_1 from the coordinates of terminal point P_2. The transformed vector will be equivalent to the original vector.

The *components* of a vector are the projections of the vector on the coordinate axes. (For a zero-based vector, the components and the coordinates of the endpoint are the same.) Simple trigonometric principles are used to resolve a vector into its components. A vector constructed from its components is known as a *resultant vector.*

$$V_x = |\mathbf{V}| \cos \phi_x \quad 5.3$$

$$V_y = |\mathbf{V}| \cos \phi_y \quad 5.4$$

$$V_z = |\mathbf{V}| \cos \phi_z \quad 5.5$$

$$|\mathbf{V}| = \sqrt{V_x^2 + V_y^2 + V_z^2} \quad 5.6$$

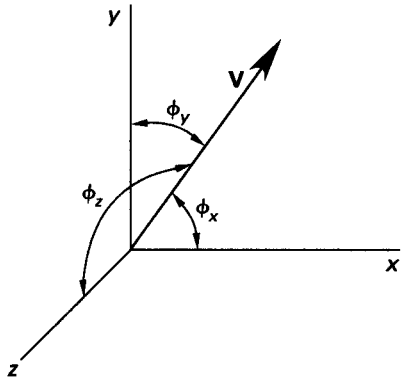

Figure 5.2 *Direction Angles of a Vector*

In Eqs. 5.3 through 5.5, ϕ_x, ϕ_y, and ϕ_z are the *direction angles*—the angles between the vector and the x-, y-, and z-axis, respectively. The cosines of these angles are known as *direction cosines.* The sum of the squares of the direction cosines is equal to 1.

$$\cos^2 \phi_x + \cos^2 \phi_y + \cos^2 \phi_z = 1 \quad 5.7$$

3. UNIT VECTORS

Unit vectors are vectors with unit magnitudes (i.e., magnitudes of 1). They are represented in the same notation as other vectors. (Unit vectors in this book are written in boldface type.) Although they can have any direction, the standard unit vectors (the *Cartesian unit vectors* **i**, **j**, and **k**) have the directions of the x-, y-, and z-coordinate axes and constitute the *Cartesian triad.*

A vector **V** can be written in terms of unit vectors and its components.

$$\mathbf{V} = |\mathbf{V}|\,\mathbf{a} = V_x\mathbf{i} + V_y\mathbf{j} + V_z\mathbf{k} \quad 5.8$$

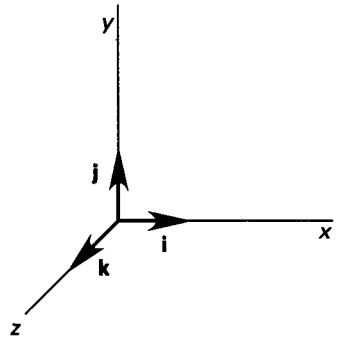

Figure 5.3 *Cartesian Unit Vectors*

The unit vector, **a**, has the same direction as the vector **V** but has a length of 1. This unit vector is calculated by dividing the original vector, **V**, by its magnitude, $|\mathbf{V}|$.

$$\mathbf{a} = \frac{\mathbf{V}}{|\mathbf{V}|} = \frac{V_x\mathbf{i} + V_y\mathbf{j} + V_z\mathbf{k}}{\sqrt{V_x^2 + V_y^2 + V_z^2}} \quad 5.9$$

4. VECTOR REPRESENTATION

The most common method of representing a vector is by writing it in *rectangular form*—a vector sum of its orthogonal components. In rectangular form, each of the orthogonal components has the same units as the resultant vector.

$$\mathbf{A} \equiv A_x\mathbf{i} + A_y\mathbf{j} + A_z\mathbf{k} \qquad \text{[three dimensions]}$$

However, the vector is also completely defined by its magnitude and associated angle. These two quantities can be written together in *phasor form*, sometimes referred to as *polar form.*

$$\mathbf{A} \equiv |\mathbf{A}| \angle \phi = A \angle \phi$$

5. CONVERSION BETWEEN SYSTEMS

The choice of the **ijk** triad may be convenient but is arbitrary. A vector can be expressed in terms of another set of unit vectors, **uvw**.

$$\mathbf{V} = V_x\mathbf{i} + V_y\mathbf{j} + V_z\mathbf{k} = V'_x\mathbf{u} + V'_y\mathbf{v} + V'_z\mathbf{w} \quad 5.10$$

The two representations are related.

$$V'_x = \mathbf{V} \cdot \mathbf{u} = (\mathbf{i} \cdot \mathbf{u})\,V_x + (\mathbf{j} \cdot \mathbf{u})\,V_y + (\mathbf{k} \cdot \mathbf{u})\,V_z \quad 5.11$$

$$V'_y = \mathbf{V} \cdot \mathbf{v} = (\mathbf{i} \cdot \mathbf{v})\,V_x + (\mathbf{j} \cdot \mathbf{v})\,V_y + (\mathbf{k} \cdot \mathbf{v})\,V_z \quad 5.12$$

$$V'_z = \mathbf{V} \cdot \mathbf{w} = (\mathbf{i} \cdot \mathbf{w})\,V_x + (\mathbf{j} \cdot \mathbf{w})\,V_y + (\mathbf{k} \cdot \mathbf{w})\,V_z \quad 5.13$$

Equations 5.11 through 5.13 can be expressed in matrix form. The dot products are known as the *coefficients of*

transformation, and the matrix containing them is the *transformation matrix*.

$$\begin{pmatrix} V'_x \\ V'_y \\ V'_z \end{pmatrix} = \begin{pmatrix} \mathbf{i}\cdot\mathbf{u} & \mathbf{j}\cdot\mathbf{u} & \mathbf{k}\cdot\mathbf{u} \\ \mathbf{i}\cdot\mathbf{v} & \mathbf{j}\cdot\mathbf{v} & \mathbf{k}\cdot\mathbf{v} \\ \mathbf{i}\cdot\mathbf{w} & \mathbf{j}\cdot\mathbf{w} & \mathbf{k}\cdot\mathbf{w} \end{pmatrix} \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix} \qquad 5.14$$

6. VECTOR ADDITION

Addition of two vectors by the *polygon method* is accomplished by placing the tail of the second vector at the head (tip) of the first. The sum (i.e., the *resultant vector*) is a vector extending from the tail of the first vector to the head of the second. Alternatively, the two vectors can be considered as the two sides of a parallelogram, while the sum represents the diagonal. This is known as addition by the *parallelogram method*.

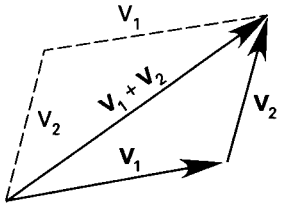

Figure 5.4 *Addition of Two Vectors*

The components of the resultant vector are the sums of the components of the added vectors ($V_{1x} + V_{2x}$, $V_{1y} + V_{2y}$, $V_{1z} + V_{2z}$).

Vector addition is both commutative and associative.

$$\mathbf{V}_1 + \mathbf{V}_2 = \mathbf{V}_2 + \mathbf{V}_1 \qquad 5.15$$

$$\mathbf{V}_1 + (\mathbf{V}_2 + \mathbf{V}_3) = (\mathbf{V}_1 + \mathbf{V}_2) + \mathbf{V}_3 \qquad 5.16$$

7. MULTIPLICATION BY A SCALAR

A vector, $\mathbf{V}$, can be multiplied by a scalar, c. If the original vector is represented by its components, each of the components is multiplied by c.

$$c\mathbf{V} = c|\mathbf{V}|\,\mathbf{a} = cV_x\mathbf{i} + cV_y\mathbf{j} + cV_z\mathbf{k} \qquad 5.17$$

Scalar multiplication is distributive.

$$c(\mathbf{V}_1 + \mathbf{V}_2) = c\mathbf{V}_1 + c\mathbf{V}_2 \qquad 5.18$$

8. VECTOR DOT PRODUCT

The *dot product* (*scalar product*), $\mathbf{V}_1 \cdot \mathbf{V}_2$, of two vectors is a scalar that is proportional to the length of the projection of the first vector onto the second vector.[4]

[4]The dot product is also written in parentheses without a dot, that is, $(\mathbf{V}_1\mathbf{V}_2)$.

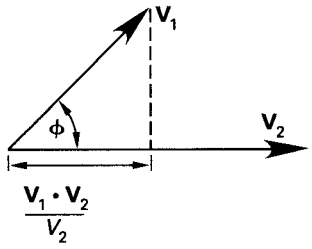

Figure 5.5 *Vector Dot Product*

The dot product is commutative and distributive.

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = \mathbf{V}_2 \cdot \mathbf{V}_1 \qquad 5.19$$

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \mathbf{V}_3 \qquad 5.20$$

The dot product can be calculated in two ways, as Eq. 5.21 indicates. ϕ is limited to 180° and is the angle between the two vectors.

$$\begin{aligned} \mathbf{V}_1 \cdot \mathbf{V}_2 &= |\mathbf{V}_1|\,|\mathbf{V}_2| \cos\phi \\ &= V_{1x}V_{2x} + V_{1y}V_{2y} + V_{1z}V_{2z} \end{aligned} \qquad 5.21$$

When Eq. 5.21 is solved for the angle between the two vectors, ϕ, it is known as the *Cauchy-Schwartz theorem*.

$$\cos\phi = \frac{V_{1x}V_{2x} + V_{1y}V_{2y} + V_{1z}V_{2z}}{|\mathbf{V}_1|\,|\mathbf{V}_2|} \qquad 5.22$$

The dot product can be used to determine whether a vector is a unit vector and to show that two vectors are orthogonal (perpendicular). For two non-null orthogonal vectors,

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = 0 \qquad 5.23$$

For any unit vector, $\mathbf{u}$,

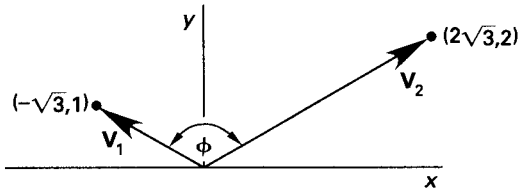
$$\mathbf{u} \cdot \mathbf{u} = 1 \qquad 5.24$$

Equations 5.23 and 5.24 can be extended to the Cartesian unit vectors.

$$\mathbf{i} \cdot \mathbf{i} = 1 \qquad 5.25$$

$$\mathbf{j} \cdot \mathbf{j} = 1 \qquad 5.26$$

$$\mathbf{k} \cdot \mathbf{k} = 1 \qquad 5.27$$



$$\mathbf{i} \cdot \mathbf{j} = 0 \qquad 5.28$$

$$\mathbf{i} \cdot \mathbf{k} = 0 \qquad 5.29$$

$$\mathbf{j} \cdot \mathbf{k} = 0 \qquad 5.30$$

Example 5.1

What is the angle between the zero-based vectors $\mathbf{V}_1 = (-\sqrt{3}, 1)$ and $\mathbf{V}_2 = (2\sqrt{3}, 2)$?

Solution

From Eq. 5.22,

$$\cos\phi = \frac{V_{1x}V_{2x} + V_{1y}V_{2y}}{|\mathbf{V}_1||\mathbf{V}_2|} = \frac{V_{1x}V_{2x} + V_{1y}V_{2y}}{\sqrt{V_{1x}^2 + V_{1y}^2}\sqrt{V_{2x}^2 + V_{2y}^2}}$$

$$= \frac{(-\sqrt{3})(2\sqrt{3}) + (1)(2)}{\sqrt{(-\sqrt{3})^2 + (1)^2}\sqrt{(2\sqrt{3})^2 + (2)^2}}$$

$$= \frac{-4}{8} = -\tfrac{1}{2}$$

$$\phi = \arccos\left(-\tfrac{1}{2}\right) = 120^\circ$$

9. VECTOR CROSS PRODUCT

The *cross product* (*vector product*), $\mathbf{V}_1 \times \mathbf{V}_2$, of two vectors is a vector that is orthogonal (perpendicular) to the plane of the two vectors.[5] The unit vector representation of the cross product can be calculated as a third-order determinant.

$$\mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & V_{1x} & V_{2x} \\ \mathbf{j} & V_{1y} & V_{2y} \\ \mathbf{k} & V_{1z} & V_{2z} \end{vmatrix} \qquad 5.31$$

The direction of the cross-product vector corresponds to the direction a right-hand screw would progress if vectors $\mathbf{V}_1$ and $\mathbf{V}_2$ are placed tail-to-tail in the plane they define and $\mathbf{V}_1$ is rotated into $\mathbf{V}_2$. The direction can also be found from the *right-hand rule.*

The magnitude of the cross product can be determined from Eq. 5.32, in which ϕ is the angle between the two vectors and is limited to 180°. The magnitude corresponds to the area of a parallelogram that has $\mathbf{V}_1$ and $\mathbf{V}_2$ as two of its sides.

$$|\mathbf{V}_1 \times \mathbf{V}_2| = |\mathbf{V}_1||\mathbf{V}_2| \sin\phi \qquad 5.32$$

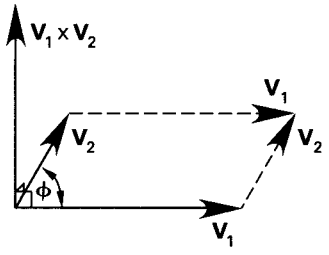


Figure 5.6 *Vector Cross Product*

Vector cross multiplication is distributive but not commutative.

$$\mathbf{V}_1 \times \mathbf{V}_2 = -(\mathbf{V}_2 \times \mathbf{V}_1) \qquad 5.33$$

$$c(\mathbf{V}_1 \times \mathbf{V}_2) = (c\mathbf{V}_1) \times \mathbf{V}_2 = \mathbf{V}_1 \times (c\mathbf{V}_2) \qquad 5.34$$

$$\mathbf{V}_1 \times (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \times \mathbf{V}_2 + \mathbf{V}_1 \times \mathbf{V}_3 \qquad 5.35$$

[5]The cross product is also written in square brackets without a cross, that is, $[\mathbf{V}_1\mathbf{V}_2]$.

If the two vectors are parallel, their cross product will be zero.

$$\mathbf{i} \times \mathbf{i} = \mathbf{j} \times \mathbf{j} = \mathbf{k} \times \mathbf{k} = 0 \qquad 5.36$$

Equation 5.36 can be extended to the unit vectors.

$$\mathbf{i} \times \mathbf{j} = -\mathbf{j} \times \mathbf{i} = \mathbf{k} \qquad 5.37$$

$$\mathbf{j} \times \mathbf{k} = -\mathbf{k} \times \mathbf{j} = \mathbf{i} \qquad 5.38$$

$$\mathbf{k} \times \mathbf{i} = -\mathbf{i} \times \mathbf{k} = \mathbf{j} \qquad 5.39$$

Example 5.2

Find a unit vector orthogonal to $\mathbf{V}_1 = \mathbf{i} - \mathbf{j} + 2\mathbf{k}$ and $\mathbf{V}_2 = 3\mathbf{j} - \mathbf{k}$.

Solution

The cross product is a vector orthogonal to $\mathbf{V}_1$ and $\mathbf{V}_2$.

$$\mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & 1 & 0 \\ \mathbf{j} & -1 & 3 \\ \mathbf{k} & 2 & -1 \end{vmatrix}$$

$$= -5\mathbf{i} + \mathbf{j} + 3\mathbf{k}$$

Check to see whether this is a unit vector.

$$|\mathbf{V}_1 \times \mathbf{V}_2| = \sqrt{(-5)^2 + (1)^2 + (3)^2} = \sqrt{35}$$

Since its length is $\sqrt{35}$, the vector must be divided by $\sqrt{35}$ to obtain a unit vector.

$$\mathbf{a} = \frac{-5\mathbf{i} + \mathbf{j} + 3\mathbf{k}}{\sqrt{35}}$$

10. MIXED TRIPLE PRODUCT

The *mixed triple product* (*triple scalar product* or just *triple product*) of three vectors is a scalar quantity representing the volume of a parallelepiped with the three vectors making up the sides. It is calculated as a determinant. Since Eq. 5.40 can be negative, the absolute value must be used to obtain the volume in that case.

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = \begin{vmatrix} V_{1x} & V_{1y} & V_{1z} \\ V_{2x} & V_{2y} & V_{2z} \\ V_{3x} & V_{3y} & V_{3z} \end{vmatrix} \qquad 5.40$$

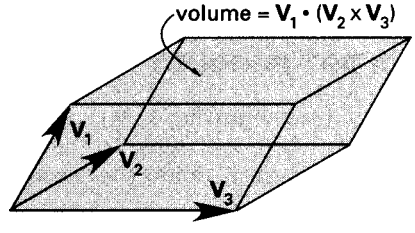

Figure 5.7 *Vector Mixed Triple Product*

The mixed triple product has the property of *circular permutation*, as defined by Eq. 5.41.

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \times \mathbf{V}_2) \cdot \mathbf{V}_3 \qquad 5.41$$

11. VECTOR TRIPLE PRODUCT

The *vector triple product* is a vector defined by Eq. 5.42. The quantities in parentheses on the right-hand side are scalars.

$$\mathbf{V}_1 \times (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \cdot \mathbf{V}_3)\mathbf{V}_2 - (\mathbf{V}_1 \cdot \mathbf{V}_2)\mathbf{V}_3 \qquad 5.42$$

12. VECTOR FUNCTIONS

A vector can be a function of another parameter. For example, a vector $\mathbf{V}$ is a function of variable t when its V_x, V_y, and V_z are functions of t.

$$\mathbf{V}(t) = (2t - 3)\mathbf{i} + (t^2 + 1)\mathbf{j} + (-7t + 5)\mathbf{k} \qquad 5.43$$

When the functions of t are differentiated (or integrated) with respect to t, the vector itself is differentiated (integrated).[6] (Chapters 8 and 9 cover differentiation and integration.)

$$\frac{d\mathbf{V}(t)}{dt} = \left(\frac{dV_x}{dt}\right)\mathbf{i} + \left(\frac{dV_y}{dt}\right)\mathbf{j} + \left(\frac{dV_z}{dt}\right)\mathbf{k} \qquad 5.44$$

Similarly, the integral of the vector is

$$\int \mathbf{V}(t)\,dt = \mathbf{i}\int V_x\,dt + \mathbf{j}\int V_y\,dt + \mathbf{k}\int V_z\,dt \qquad 5.45$$

[6]This is particularly valuable when converting among position, velocity, and acceleration vectors.

Practice Problems 6-6

1. DEGREES AND RADIANS

Degrees and *radians* are two units for measuring angles. One complete circle is divided into 360 degrees (written 360°) or 2π radians (abbreviated *rad*).[1] The conversions between degrees and radians are

multiply	by	to obtain
radians	$\frac{180}{\pi}$	degrees
degrees	$\frac{\pi}{180}$	radians

The number of radians in an angle θ corresponds to the area within a circular sector with arc length θ and a radius of one. Alternatively, the area of a sector with central angle θ radians is $\theta/2$ for a *unit circle* (i.e., a circle with a radius of one unit).

[1]The abbreviation *rad* is also used to represent *radiation absorbed dose*, a measure of radiation exposure.

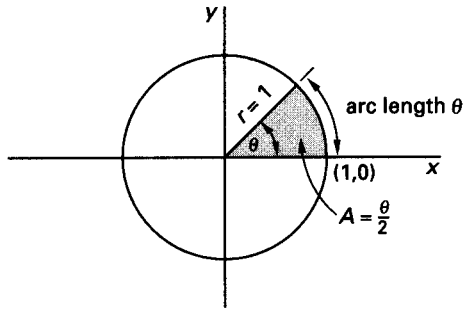

Figure 6.1 *Radians and Area of Unit Circle*

2. PLANE ANGLES

A *plane angle* (usually referred to as just an *angle*) consists of two intersecting lines and an intersection point known as the *vertex*. The angle can be referred to by a capital letter representing the vertex (e.g., B in Fig. 6.2), a Greek letter representing the angular measure (e.g., β), or by three capital letters, where the middle letter is the vertex and the other two letters are two points on different lines, and either the symbol $\angle$ or $\measuredangle$ (e.g., $\measuredangle$ABC).

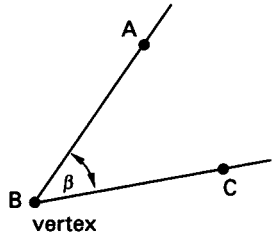

Figure 6.2 *Angle*

The angle between two intersecting lines generally is understood to be the smaller angle created.[2] Angles have been classified as follows.

- *acute angle*: an angle less than 90° ($\pi/2$ rad)
- *obtuse angle*: an angle more than 90° ($\pi/2$ rad) but less than 180° (π rad)
- *reflex angle*: an angle more than 180° (π rad) but less than 360° (2π rad)

[2]In books on geometry, the term *ray* is used instead of *line*.

- *related angle*: an angle that differs from another by some multiple of 90° ($\pi/2$ rad)
- *right angle*: an angle equal to 90° ($\pi/2$ rad)
- *straight angle*: an angle equal to 180° (π rad), that is, a straight line

Complementary angles are two angles whose sum is 90° ($\pi/2$ rad). *Supplementary angles* are two angles whose sum is 180° (π rad). *Adjacent angles* share a common vertex and one (the interior) side. Adjacent angles are supplementary only if their exterior sides form a straight line.

Vertical angles are the two angles with a common vertex and with sides made up by two intersecting straight lines. Vertical angles are equal.

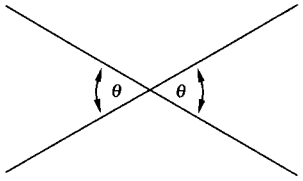

Figure 6.3 *Vertical Angles*

Angle of elevation and *angle of depression* are surveying terms referring to the angle above and below the horizontal plane of the observer, respectively.

3. TRIANGLES

A *triangle* is a three-sided closed polygon with three angles whose sum is 180° (π rad). Triangles are identified by their vertices and the symbol Δ (e.g., ΔABC in Fig. 6.4). A side is designated by its two endpoints (e.g., AB in Fig. 6.4) or by a lowercase letter corresponding to the capital letter of the opposite vertex (e.g., c).

In *similar triangles*, the corresponding angles are equal and the corresponding sides are in proportion. (Since there are only two independent angles in a triangle, showing that two angles of one triangle are equal to two angles of the other triangle is sufficient to show similarity.) The symbol for similarity is $\sim$. In Fig. 6.4, $\Delta ABC \sim \Delta DEF$ (i.e., ΔABC is similar to ΔDEF).

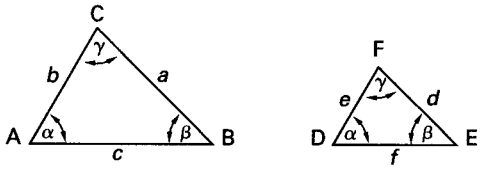

Figure 6.4 *Similar Triangles*

4. RIGHT TRIANGLES

A *right triangle* is a triangle in which one of the angles is 90° ($\pi/2$ rad). The remaining two angles are complementary. If one of the acute angles is chosen as the reference, the sides forming the right angle are known as the *adjacent side*, x, and the *opposite side*, y. The longest side is known as the *hypotenuse*, r. The *Pythagorean theorem* relates the lengths of these sides.

$$x^2 + y^2 = r^2 \qquad 6.1$$

In certain cases, the lengths of unknown sides of right triangles can be determined by inspection.[3] This occurs when the lengths of the sides are in the ratios of 3:4:5, 1:1:$\sqrt{2}$, 1:$\sqrt{3}$:2, and 5:12:13.

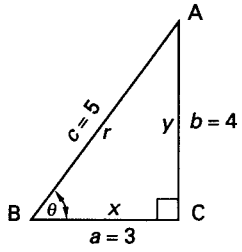

Figure 6.5 *3:4:5 Right Triangle*

5. CIRCULAR TRANSCENDENTAL FUNCTIONS

The *circular transcendental functions* (usually referred to as the *transcendental functions*, *trigonometric functions*, or *functions of an angle*) are calculated from the sides of a right triangle. Equations 6.2 through 6.7 refer to Fig. 6.5.

$$\text{sine: } \sin\theta = \frac{y}{r} = \frac{\text{opposite}}{\text{hypotenuse}} \qquad 6.2$$

$$\text{cosine: } \cos\theta = \frac{x}{r} = \frac{\text{adjacent}}{\text{hypotenuse}} \qquad 6.3$$

$$\text{tangent: } \tan\theta = \frac{y}{x} = \frac{\text{opposite}}{\text{adjacent}} \qquad 6.4$$

$$\text{cotangent: } \cot\theta = \frac{x}{y} = \frac{\text{adjacent}}{\text{opposite}} \qquad 6.5$$

$$\text{secant: } \sec\theta = \frac{r}{x} = \frac{\text{hypotenuse}}{\text{adjacent}} \qquad 6.6$$

$$\text{cosecant: } \csc\theta = \frac{r}{y} = \frac{\text{hypotenuse}}{\text{opposite}} \qquad 6.7$$

[3]These cases are almost always contrived examples. There is nothing intrinsic in nature to cause the formation of triangles with these proportions.

Three of the transcendental functions are reciprocals of the others. Notice that, while the tangent and cotangent functions are reciprocals of each other, the sine and cosine functions are not.

$$\cot\theta = \frac{1}{\tan\theta} \qquad 6.8$$

$$\sec\theta = \frac{1}{\cos\theta} \qquad 6.9$$

$$\csc\theta = \frac{1}{\sin\theta} \qquad 6.10$$

The trigonometric functions correspond to the lengths of various line segments in a right triangle with a unit hypotenuse. Figure 6.6 shows such a triangle inscribed in a unit circle.

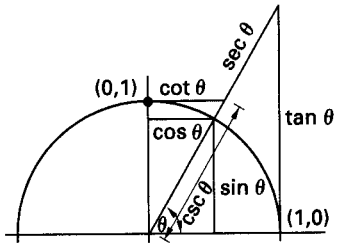

Figure 6.6 *Trigonometric Functions in a Unit Circle*

6. SMALL ANGLE APPROXIMATIONS

When an angle is very small, the hypotenuse and adjacent sides are essentially equal in length and certain approximations can be made. (The angle θ must be expressed in radians in Eqs. 6.11 and 6.12.)

$$\sin\theta \approx \tan\theta \approx \theta \Big|_{\theta<10^\circ \ (0.175 \text{ rad})} \qquad 6.11$$

$$\cos\theta \approx 1 \Big|_{\theta<5^\circ \ (0.0873 \text{ rad})} \qquad 6.12$$

7. GRAPHS OF THE FUNCTIONS

Figure 6.7 illustrates the periodicity of the sine, cosine, and tangent functions.[4]

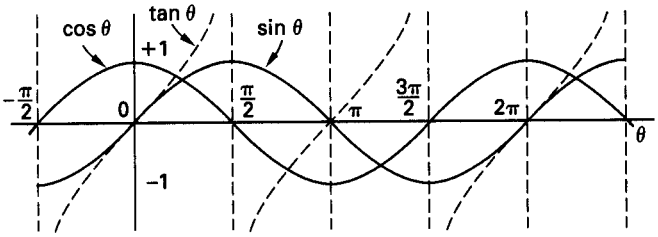

Figure 6.7 *Graphs of Sine, Cosine, and Tangent Functions*

[4]The remaining functions, being reciprocals of these three functions, are also periodic.

8. SIGNS OF THE FUNCTIONS

Table 6.1 shows how the sine, cosine, and tangent functions vary in sign with different values of θ. All three functions are positive for angles $0^\circ \le \theta \le 90^\circ$ ($0 \le \theta \le \pi/2$ rad), but only the sine is positive for angles $90^\circ < \theta \le 180^\circ$ ($\pi/2$ rad $< \theta \le \pi$ rad). The concept of quadrants is used to summarize the signs of the functions: angles up to 90° ($\pi/2$ rad) are in quadrant I, between 90° and 180° ($\pi/2$ and π rad) are in quadrant II, and so on.

Table 6.1 *Signs of the Functions by Quadrant*

	quadrant			
function	I	II	III	IV
sine	+	+	−	−
cosine	+	−	−	+
tangent	+	−	+	−

9. FUNCTIONS OF RELATED ANGLES

Figure 6.7 shows that the sine, cosine, and tangent curves are symmetrical with respect to the horizontal axis. Furthermore, portions of the curves are symmetrical with respect to a vertical axis. The values of the sine and cosine functions repeat every 360° (2π rad), and the absolute values repeat every 180° (π rad). This can be written as

$$\sin(\theta + 180^\circ) = -\sin\theta \qquad 6.13$$

Similarly, the tangent function repeats every 180° (π rad), and its absolute value repeats every 90° ($\pi/2$ rad).

Table 6.2 summarizes the functions of the related angles.

Table 6.2 *Functions of Related Angles*

$f(\theta)$	$-\theta$	$90^\circ - \theta$	$90^\circ + \theta$	$180^\circ - \theta$	$180^\circ + \theta$
sin	$-\sin\theta$	$\cos\theta$	$\cos\theta$	$\sin\theta$	$-\sin\theta$
cos	$\cos\theta$	$\sin\theta$	$-\sin\theta$	$-\cos\theta$	$-\cos\theta$
tan	$-\tan\theta$	$\cot\theta$	$-\cot\theta$	$-\tan\theta$	$\tan\theta$

10. TRIGONOMETRIC IDENTITIES

There are many relationships between trigonometric functions. For example, Eqs. 6.14 through 6.16 are well known.

$$\sin^2\theta + \cos^2\theta = 1 \qquad 6.14$$

$$1 + \tan^2\theta = \sec^2\theta \qquad 6.15$$

$$1 + \cot^2\theta = \csc^2\theta \qquad 6.16$$

Other relatively common identities are listed as follows.[5]

- *double-angle formulas*:

$$\sin 2\theta = 2\sin\theta\cos\theta = \frac{2\tan\theta}{1+\tan^2\theta} \quad 6.17$$

$$\cos 2\theta = \cos^2\theta - \sin^2\theta = 1 - 2\sin^2\theta = 2\cos^2\theta - 1 = \frac{1-\tan^2\theta}{1+\tan^2\theta} \quad 6.18$$

$$\tan 2\theta = \frac{2\tan\theta}{1-\tan^2\theta} \quad 6.19$$

$$\cot 2\theta = \frac{\cot^2\theta - 1}{2\cot\theta} \quad 6.20$$

- *two-angle formulas*:

$$\sin(\theta \pm \phi) = \sin\theta\cos\phi \pm \cos\theta\sin\phi \quad 6.21$$

$$\cos(\theta \pm \phi) = \cos\theta\cos\phi \mp \sin\theta\sin\phi \quad 6.22$$

$$\tan(\theta \pm \phi) = \frac{\tan\theta \pm \tan\phi}{1 \mp \tan\theta\tan\phi} \quad 6.23$$

$$\cot(\theta \pm \phi) = \frac{\cot\phi\cot\theta \mp 1}{\cot\phi \pm \cot\theta} \quad 6.24$$

- *half-angle formulas* ($\theta < 180°$):

$$\sin\frac{\theta}{2} = \sqrt{\frac{1-\cos\theta}{2}} \quad 6.25$$

$$\cos\frac{\theta}{2} = \sqrt{\frac{1+\cos\theta}{2}} \quad 6.26$$

$$\tan\frac{\theta}{2} = \sqrt{\frac{1-\cos\theta}{1+\cos\theta}} = \frac{\sin\theta}{1+\cos\theta} = \frac{1-\cos\theta}{\sin\theta} \quad 6.27$$

- *miscellaneous formulas* ($\theta < 90°$):

$$\sin\theta = 2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right) \quad 6.28$$

$$\sin\theta = \sqrt{\frac{1-\cos 2\theta}{2}} \quad 6.29$$

$$\cos\theta = \cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right) \quad 6.30$$

$$\cos\theta = \sqrt{\frac{1+\cos 2\theta}{2}} \quad 6.31$$

$$\tan\theta = \frac{2\tan\left(\frac{\theta}{2}\right)}{1-\tan^2\left(\frac{\theta}{2}\right)} = \frac{2\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)}{\cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)} \quad 6.32$$

$$\tan\theta = \sqrt{\frac{1-\cos 2\theta}{1+\cos 2\theta}} = \frac{\sin 2\theta}{1+\cos 2\theta} = \frac{1-\cos 2\theta}{\sin 2\theta} \quad 6.33$$

$$\cot\theta = \frac{\cot^2\left(\frac{\theta}{2}\right) - 1}{2\cot\left(\frac{\theta}{2}\right)} = \frac{\cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)}{2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)} \quad 6.34$$

$$\cot\theta = \sqrt{\frac{1+\cos 2\theta}{1-\cos 2\theta}} = \frac{1+\cos 2\theta}{\sin 2\theta} = \frac{\sin 2\theta}{1-\cos 2\theta} \quad 6.35$$

11. INVERSE TRIGONOMETRIC FUNCTIONS

Finding an angle from a known trigonometric function is a common operation known as an *inverse trigonometric operation.* The inverse function can be designated by adding "inverse," "arc-," or the superscript -1 to the name of the function. For example,

$$\text{inverse}\sin(0.5) = \arcsin(0.5) = \sin^{-1}(0.5) = 30°$$

12. HYPERBOLIC TRANSCENDENTAL FUNCTIONS

Hyperbolic transcendental functions (normally referred to as *hyperbolic functions*) are specific equations containing combinations of the terms e^{θ} and $e^{-\theta}$. These combinations appear regularly in certain types of problems (e.g., analysis of cables and heat transfer from fins) and are given specific names and symbols to simplify presentation.[6]

$$\text{hyperbolic sine: } \sinh\theta = \frac{e^{\theta} - e^{-\theta}}{2} \quad 6.36$$

$$\text{hyperbolic cosine: } \cosh\theta = \frac{e^{\theta} + e^{-\theta}}{2} \quad 6.37$$

[5]It is an idiosyncrasy that these formulas are conventionally referred to as *formulas*, not *identities.*

[6]The hyperbolic sine and cosine functions are pronounced (by some) as "sinch" and "cosh," respectively.

hyperbolic tangent: $\tanh\theta = \dfrac{e^{\theta} - e^{-\theta}}{e^{\theta} + e^{-\theta}} = \dfrac{\sinh\theta}{\cosh\theta}$ 6.38

hyperbolic cotangent: $\coth\theta = \dfrac{e^{\theta} + e^{-\theta}}{e^{\theta} - e^{-\theta}} = \dfrac{\cosh\theta}{\sinh\theta}$ 6.39

hyperbolic secant: $\operatorname{sech}\theta = \dfrac{2}{e^{\theta} + e^{-\theta}} = \dfrac{1}{\cosh\theta}$ 6.40

hyperbolic cosecant: $\operatorname{csch}\theta = \dfrac{2}{e^{\theta} - e^{-\theta}} = \dfrac{1}{\sinh\theta}$ 6.41

Hyperbolic functions cannot be related to a right triangle, but they are related to a rectangular (equilateral) hyperbola, as shown in Fig. 6.8. The shaded area has a value of $\theta/2$ and is sometimes given the units of *hyperbolic radians*.

$$\sinh\theta = \frac{y}{a} \qquad 6.42$$

$$\cosh\theta = \frac{x}{a} \qquad 6.43$$

$$\tanh\theta = \frac{y}{x} \qquad 6.44$$

$$\coth\theta = \frac{x}{y} \qquad 6.45$$

$$\operatorname{sech}\theta = \frac{a}{x} \qquad 6.46$$

$$\operatorname{csch}\theta = \frac{a}{y} \qquad 6.47$$

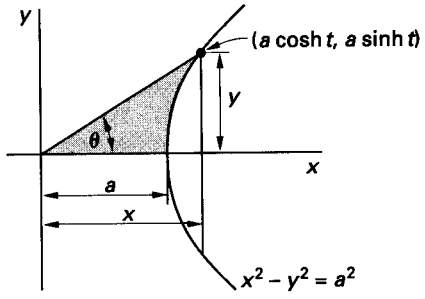

Figure 6.8 *Equilateral Hyperbola and Hyperbolic Functions*

13. HYPERBOLIC IDENTITIES

The hyperbolic identities are different from the standard trigonometric identities. Some of the most important identities are presented as follows.

$$\cosh^2\theta - \sinh^2\theta = 1 \qquad 6.48$$

$$1 - \tanh^2\theta = \operatorname{sech}^2\theta \qquad 6.49$$

$$1 - \coth^2\theta = -\operatorname{csch}^2\theta \qquad 6.50$$

$$\cosh\theta + \sinh\theta = e^{\theta} \qquad 6.51$$

$$\cosh\theta - \sinh\theta = e^{-\theta} \qquad 6.52$$

$$\sinh(\theta \pm \phi) = \sinh\theta\cosh\phi \pm \cosh\theta\sinh\phi \qquad 6.53$$

$$\cosh(\theta \pm \phi) = \cosh\theta\cosh\phi \pm \sinh\theta\sinh\phi \qquad 6.54$$

$$\tanh(\theta \pm \phi) = \frac{\tanh\theta \pm \tanh\phi}{1 \pm \tanh\theta\tanh\phi} \qquad 6.55$$

14. GENERAL TRIANGLES

A *general triangle* (also known as an *oblique triangle*) is one that is not specifically a right triangle, as shown in Fig. 6.9. Equation 6.56 calculates the area of a general triangle.[7]

$$\text{area} = \tfrac{1}{2}ab\sin C = \tfrac{1}{2}bc\sin A = \tfrac{1}{2}ca\sin B \qquad 6.56$$

The *law of sines* (Eq. 6.57) relates the sides and the sines of the angles.

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c} \qquad 6.57$$

The *law of cosines* relates the cosine of an angle to an opposite side. (Equation 6.58 can be extended to the two remaining sides.)

$$a^2 = b^2 + c^2 - 2bc\cos A \qquad 6.58$$

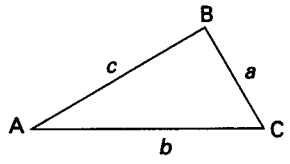

Figure 6.9 *General Triangle*

The *law of tangents* relates the sum and difference of two sides. (Equation 6.59 can be extended to the two remaining sides.)

$$\frac{a-b}{a+b} = \frac{\tan\left(\dfrac{A-B}{2}\right)}{\tan\left(\dfrac{A+B}{2}\right)} \qquad 6.59$$

15. SPHERICAL TRIGONOMETRY

A *spherical triangle* is a triangle that has been drawn on the surface of a sphere, as shown in Fig. 6.10. The *trihedral angle* O–ABC is formed when the vertices A, B, and C are joined to the center of the sphere. The *face angles* (BOC, COA, and AOB in Fig. 6.10) are used to measure the sides (a, b, and c in Fig. 6.10). The *vertex angles* are A, B, and C. Thus, angles are used to measure both vertex angles and sides.

[7] Other methods of calculating the area of a general triangle are given in Chap. 7.

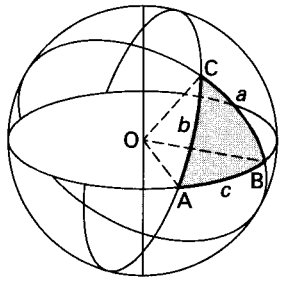

Figure 6.10 *Spherical Triangle ABC*

The following rules are valid for spherical triangles for which each side and angle is less than 180°.

- The sum of the three vertex angles is greater than 180° and less than 540°.

$$180° < A + B + C < 540° \qquad 6.60$$

- The sum of any two sides is greater than the third side.
- The sum of the three sides is less than 360°.

$$0° < a + b + c < 360° \qquad 6.61$$

- If the two sides are equal, the corresponding angles opposite are equal, and the converse is also true.
- If two sides are unequal, the corresponding angles opposite are unequal. The greater angle is opposite the greater side.

The *spherical excess*, ϵ, is the amount by which the sum of the vertex angles exceeds 180°. The *spherical defect*, d, is the amount by which the sum of the sides differs from 360°.

$$\epsilon = A + B + C - 180° \qquad 6.62$$

$$d = 360° - (a + b + c) \qquad 6.63$$

There are many trigonometric identities that define the relationships between angles in a spherical triangle. Some of the more common identities are presented as follows.

- *law of sines*:

$$\frac{\sin A}{\sin a} = \frac{\sin B}{\sin b} = \frac{\sin C}{\sin c} \qquad 6.64$$

- *first law of cosines*:

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \qquad 6.65$$

- *second law of cosines*:

$$\cos A = -\cos B \cos C + \sin B \sin C \cos a \qquad 6.66$$

16. SOLID ANGLES

A *solid angle*, ω, is a measure of the angle subtended at the vertex of a cone. The solid angle has units of *steradians* (abbreviated *sr*). A steradian is the solid angle subtended at the center of a unit sphere (i.e., a sphere with a radius of one) by a unit area on its surface. Since the surface area of a sphere of radius r is r^2 times the surface area of a unit sphere, the solid angle is equal to the area cut out by the cone divided by r^2. (The surface area of a spherical segment is given in App. 7.B.)

$$\omega = \frac{\text{surface area}}{r^2} \qquad 6.67$$

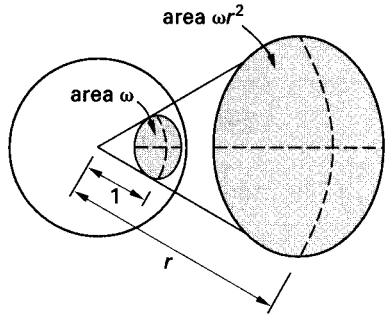

Figure 6.11 *Solid Angle*

PRACTICE PROBLEMS

1. A 5 lbm (5 kg) block sits on a 20° incline without slipping. (a) Draw the freebody with respect to axes parallel and perpendicular to the surface of the incline. (b) Determine the magnitude of the frictional force on the block.

(A) 1.71 lbf (16.8 N)
(B) 3.35 lbf (32.9 N)
(C) 4.70 lbf (46.1 N)
(D) 5.00 lbf (49.1 N)

The answer is (A).

Practice Problems 7-12

1. MENSURATION OF REGULAR SHAPES

The dimensions, perimeter, area, and other geometric properties constitute the *mensuration* (i.e., the measurements) of a geometric shape. Appendices 7.A and 7.B contain formulas and tables used to calculate these properties.

Example 7.1

In the study of open channel fluid flow, the hydraulic radius is defined as the ratio of flow area to wetted perimeter. What is the hydraulic radius of a 6 in diameter pipe filled to a depth of 2 in?

Solution

Points O, B, and C constitute a circular segment and are used to find the central angle of the circular segment.

$$\left(\tfrac{1}{2}\right)(\angle \mathrm{BOC}) = \arccos\left(\tfrac{1}{3}\right) = 70.53^\circ$$

$$\phi = \angle \mathrm{BOC} = (2)(70.53^\circ) = 141.06^\circ = 2.462 \text{ rad}$$

From App. 7.A, the area in flow and arc length are

$$\begin{aligned} A &= \tfrac{1}{2}r^2(\phi - \sin\phi) \\ &= \left(\tfrac{1}{2}\right)(3\,\text{in})^2[2.462\,\text{rad} - \sin(2.462\,\text{rad})] \\ &= 8.251\,\text{in}^2 \end{aligned}$$

$$\begin{aligned} s &= r\phi \\ &= (3\,\text{in})(2.462\,\text{rad}) = 7.386\,\text{in} \end{aligned}$$

The hydraulic radius is

$$\begin{aligned} r_h &= \frac{A}{S} \\ &= \frac{8.251\,\text{in}^2}{7.386\,\text{in}} = 1.12\,\text{in} \end{aligned}$$

2. AREAS WITH IRREGULAR BOUNDARIES

Areas of sections with irregular boundaries (such as creek banks) cannot be determined precisely, and approximation methods must be used. If the irregular side can be divided into a series of cells of equal width, either the trapezoidal rule or Simpson's rule can be used.

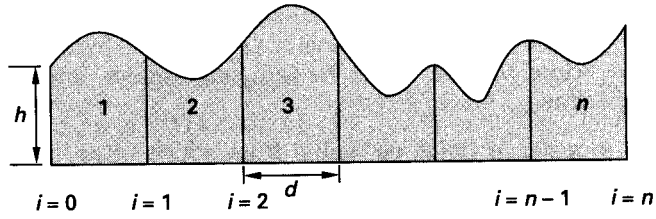

Figure 7.1 *Irregular Areas*

If the irregular side of each cell is fairly straight, the *trapezoidal rule* is appropriate.

$$A = \left(\frac{d}{2}\right)\left(h_0 + h_n + 2\sum_{i=1}^{n-1} h_i\right) \qquad 7.1$$

If the irregular side of each cell is curved (parabolic), *Simpson's rule* should be used. (n must be even to use Simpson's rule.)

$$A = \left(\frac{d}{3}\right)\left(h_0 + h_n + 4\sum_{\substack{i \text{ odd}\\ i=1}}^{n-1} h_i + 2\sum_{\substack{i \text{ even}\\ i=2}}^{n-2} h_i\right) \qquad 7.2$$

3. GEOMETRIC DEFINITIONS

The following terms are used in this book to describe the relationship or orientation of one geometric figure to another.

- *abscissa*: the horizontal coordinate, typically designated as x in a rectangular coordinate system
- *asymptote*: a straight line that is approached but not intersected by a curved line
- *asymptotic*: approaching the slope of another line; attaining the slope of another line in the limit
- *center*: a point equidistant from all other points
- *collinear*: falling on the same line
- *concave*: curved inward (in the direction indicated)[1]
- *convex*: curved outward (in the direction indicated)
- *convex hull*: a closed figure whose surface is convex everywhere
- *coplanar*: falling on the same plane
- *inflection point*: a point where the second derivative changes sign or the curve changes from concave to convex. (Also known as a *point of contraflexure.*)
- *locus of points*: a set or collection of points having some common property and being so infinitely close together as to be indistinguishable from a line
- *node*: a point on a line from which other lines enter or leave
- *normal*: rotated 90°; being at right angles
- *ordinate*: the vertical coordinate, typically designated as y in a rectangular coordinate system
- *orthogonal*: rotated 90°; being at right angles
- *saddle point*: a point in three-dimensional space where all adjacent points are higher in one direction (the direction of the saddle) and lower in an orthogonal direction (the direction of the sides)
- *tangent*: having equal slopes at a common point

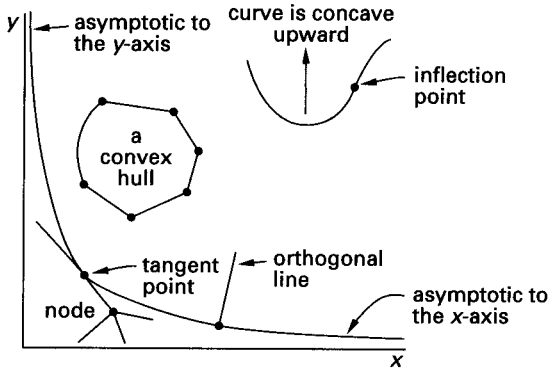

Figure 7.2 *Geometric Definitions*

4. CONCAVE CURVES

Concavity is a term that is applied to curved lines. A *concave up curve* is one whose function's first derivative increases continuously from negative to positive values. Straight lines drawn tangent to concave up curves are all below the curve. The graph of such a function may be thought of as being able to "hold water."

The first derivative of a *concave down curve* decreases continuously from positive to negative. A graph of a concave down function may be thought of as "spilling water." See Fig. 7.3.

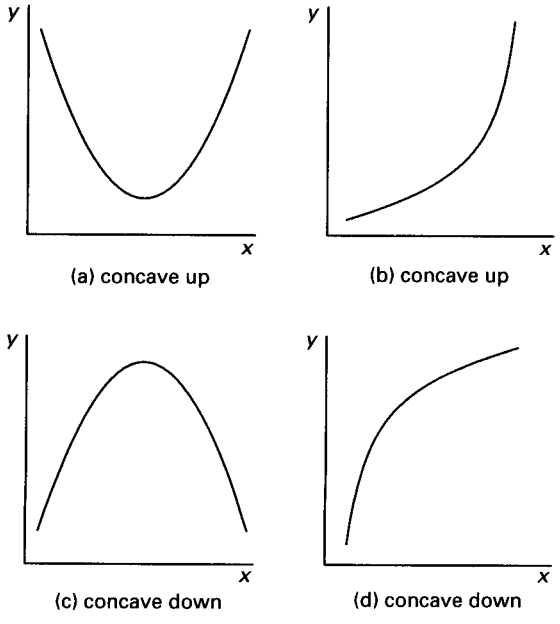

Figure 7.3 *Concave Curves*

[1]This is easily remembered since one must go inside to explore a cave.

5. CONVEX REGIONS

Convexity is a term that is applied to sets and regions.[2] It plays an important role in many mathematics subjects. A set or multidimensional region is *convex* if it contains the line segment joining any two of its points; that is, if a straight line is drawn connecting any two points in a convex region, that line will lie entirely within the region. For example, the interior of a parabola is a convex region, as is a solid sphere. The *void* or *null region* (i.e., an empty set of points), single points, and straight lines are convex sets. A convex region bounded by separate, connected line segments is known as a *convex hull*. (See Fig. 7.4.)

Within a convex region, a local maximum is also the global maximum. Similarly, a local minimum is also the global minimum. (See Sec. 8.3.) The intersection of two convex regions is also convex.

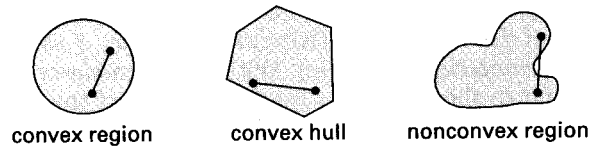

Figure 7.4 *Convexity*

6. CONGRUENCY

Congruence in geometric figures is analogous to *equality* in algebraic expressions. Congruent line segments are segments that have the same length. Congruent angles have the same angular measure. Congruent triangles have the same vertex angles and side lengths.

In general, *congruency*, indicated by the symbol $\cong$, means that there is one-to-one correspondence between all points on two objects. This correspondence is defined by the *mapping function* or *isometry*, which can be a translation, rotation, or reflection. Since the identity function is a valid mapping function, every geometric shape is congruent to itself.

Two congruent objects can be in different spaces. For example, a triangular area in three-dimensional space can be mapped into a triangle in two-dimensional space.

[2]It is tempting to define regions that fail the convexity test as being "concave." However, it is more proper to define such regions as "nonconvex." In any case, it is important to recognize that convexity depends on the reference point: An observer within a sphere will see the spherical boundary as convex; an observer outside the sphere may see the boundary as nonconvex.

7. COORDINATE SYSTEMS

The manner in which a geometric figure is described depends on the coordinate system that is used. The three-dimensional *rectangular coordinate system* (also known as the *Cartesian coordinate system*) with its x-, y-, and z-coordinates is the most commonly used in engineering. Table 7.1 summarizes the components needed to specify a point in the various coordinate systems. Figure 7.5 illustrates the use of and conversion between the coordinate systems.

Table 7.1 *Components of Coordinate Systems*

name	dimensions	components
rectangular	2	x, y
rectangular	3	x, y, z
polar	2	r, θ
cylindrical	3	r, θ, z
spherical	3	r, θ, ϕ

8. CURVES

A *curve* (commonly called a *line*) is a function over a finite or infinite range of the independent variable. When a curve is drawn in two- or three-dimensional space, it is known as a *graph of the curve*. It may or may not be possible to describe the curve mathematically. The *degree of a curve* is the highest exponent in the function. For example, Eq. 7.3 is a fourth-degree curve.

$$f(x) = 2x^4 + 7x^3 + 6x^2 + 3x + 9 = 0 \qquad 7.3$$

An *ordinary cycloid* (Fig. 7.6) is a curve traced out by a point on the rim of a wheel that rolls without slipping. It is described in parametric form by Eqs. 7.4 and 7.5 and in rectangular form by Eq. 7.6. In Eqs. 7.4 through 7.6, using the minus sign results in a cusp at the origin; using the plus sign results in a vertex (trough) at the origin.

$$x = r(\theta \pm \sin\theta) \qquad 7.4$$

$$y = r(1 \pm \cos\theta) \qquad 7.5$$

$$x = r \arccos\left(\frac{r-y}{r}\right) \pm \sqrt{2ry - y^2} \qquad 7.6$$

An *epicycloid* is a curve generated by a point on the rim of a wheel that rolls on the outside of a circle. A *hypocycloid* is a curve generated by a point on the rim of a wheel that rolls on the inside of a circle. The equation of a hypocycloid of four cusps is

$$x^{\frac{2}{3}} + y^{\frac{2}{3}} = r^{\frac{2}{3}} \qquad \text{[4 cusps]} \qquad 7.7$$

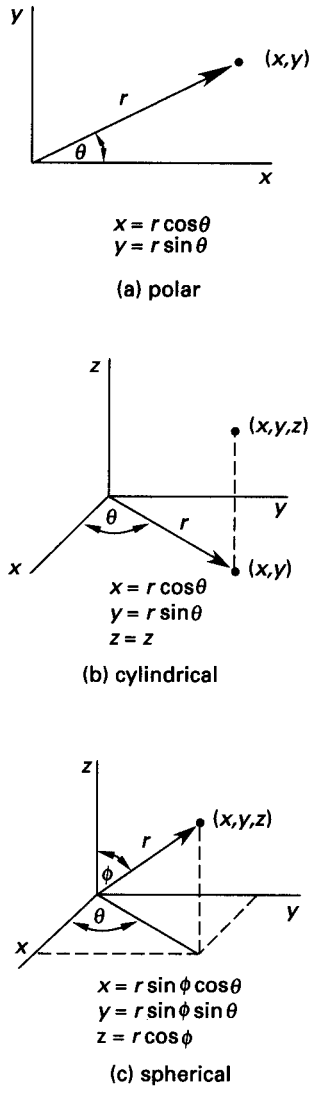

Figure 7.5 *Different Coordinate Systems*

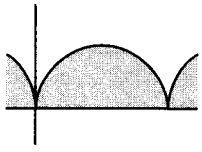

Figure 7.6 *Cycloid (cusp at origin)*

9. SYMMETRY OF CURVES

Two points, P and Q, are symmetrical with respect to a line if the line is a perpendicular bisector of the line segment PQ. If the graph of a curve is unchanged when y is replaced with $-y$, the curve is symmetrical with respect to the x-axis. If the curve is unchanged when x is replaced with $-x$, the curve is symmetrical with respect to the y-axis.

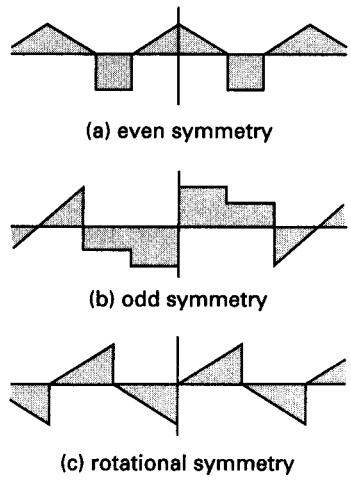

Figure 7.7 *Waveform Symmetry*

Repeating waveforms can be symmetrical with respect to the y-axis. A curve $f(x)$ is said to have *even symmetry* if $f(x) = f(-x)$. (Alternatively, $f(x)$ is said to be a *symmetrical function.*) With even symmetry, the function to the left of $x = 0$ is a reflection of the function to the right of $x = 0$. (In effect, the y-axis is a mirror.) The cosine curve is an example of a curve with even symmetry.

A curve is said to have *odd symmetry* if $f(x) = -f(-x)$. (Alternatively, $f(x)$ is said to be an *asymmetrical function.*)[3] The sine curve is an example of a curve with odd symmetry.

A curve is said to have *rotational symmetry* (*half-wave symmetry*) if $f(x) = -f(x + \pi)$.[4] Curves of this type are identical except for a sign reversal on alternate half-cycles.

Table 7.2 describes the type of function resulting from the combination of two functions.

Table 7.2 *Combinations of Functions*

	operation			
	+	−	×	÷
$f_1(x)$ even, $f_2(x)$ even	even	even	even	even
$f_1(x)$ odd, $f_2(x)$ odd	odd	odd	even	even
$f_1(x)$ even, $f_2(x)$ odd	neither	neither	odd	odd

10. STRAIGHT LINES

Figure 7.8 illustrates a straight line in two-dimensional space. The *slope* of the line is m, the *y-intercept* is b, and the *x-intercept* is a. The equation of the line

[3]The semantics of "even symmetry" and "asymmetrical function" are contradictory.

[4]The symbol π represents half of a full cycle of the waveform, not the value 3.141 . . . .

can be represented in several forms, and the procedure for finding the equation depends on the form chosen to represent the line. In general, the procedure involves substituting one or more known points on the line into the equation in order to determine the coefficients.

- *general form*:

$$Ax + By + C = 0 \qquad 7.8$$

$$A = -mB \qquad 7.9$$

$$B = \frac{-C}{b} \qquad 7.10$$

$$C = -aA = -bB \qquad 7.11$$

- *slope-intercept form*:

$$y = mx + b \qquad 7.12$$

$$m = \frac{-A}{B} = \tan\theta = \frac{y_2 - y_1}{x_2 - x_1} \qquad 7.13$$

$$b = \frac{-C}{B} \qquad 7.14$$

$$a = \frac{-C}{A} \qquad 7.15$$

- *point-slope form*:

$$y - y_1 = m(x - x_1) \qquad 7.16$$

- *intercept form*:

$$\frac{x}{a} + \frac{y}{b} = 1 \qquad 7.17$$

- *two-point form*:

$$\frac{y - y_1}{x - x_1} = \frac{y_2 - y_1}{x_2 - x_1} \qquad 7.18$$

- *normal form*:

$$x\cos\beta + y\sin\beta - d = 0 \qquad 7.19$$

(d and β are constants; x and y are variables.)

- *polar form*:

$$r = \frac{d}{\cos(\beta - \alpha)} \qquad 7.20$$

(d and β are constants; r and α are variables.)

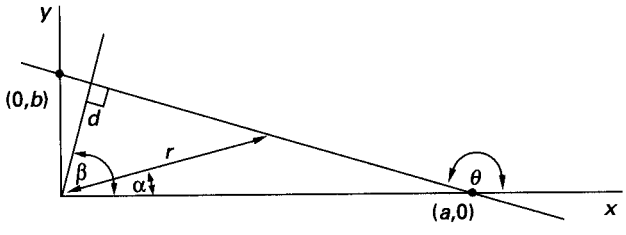

Figure 7.8 *Straight Line*

11. DIRECTION NUMBERS, ANGLES, AND COSINES

Given a directed line from (x_1, y_1, z_1) to (x_2, y_2, z_2), the *direction numbers* are

$$L = x_2 - x_1 \qquad 7.21$$

$$M = y_2 - y_1 \qquad 7.22$$

$$N = z_2 - z_1 \qquad 7.23$$

The distance between two points is

$$d = \sqrt{L^2 + M^2 + N^2} \qquad 7.24$$

The *direction cosines* are

$$\cos\alpha = \frac{L}{d} \qquad 7.25$$

$$\cos\beta = \frac{M}{d} \qquad 7.26$$

$$\cos\gamma = \frac{N}{d} \qquad 7.27$$

Note that

$$\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1 \qquad 7.28$$

The *direction angles* are the angles between the axes and the lines. They are found from the inverse functions of the direction cosines.

$$\alpha = \arccos\left(\frac{L}{d}\right) \qquad 7.29$$

$$\beta = \arccos\left(\frac{M}{d}\right) \qquad 7.30$$

$$\gamma = \arccos\left(\frac{N}{d}\right) \qquad 7.31$$

The direction cosines can be used to write the equation of the straight line in terms of the unit vectors. The line $\mathbf{R}$ would be defined as

$$\mathbf{R} = \mathbf{i}\cos\alpha + \mathbf{j}\cos\beta + \mathbf{k}\cos\gamma \qquad 7.32$$

Similarly, the line may be written in terms of its direction numbers.

$$\mathbf{R} = L\mathbf{i} + M\mathbf{j} + N\mathbf{k} \qquad 7.33$$

Example 7.2

A line passes through the points $(4, 7, 9)$ and $(0, 1, 6)$. Write the equation of the line in terms of its (a) direction numbers and (b) direction cosines.

Solution

(a) The direction numbers are

$$L = 4 - 0 = 4$$
$$M = 7 - 1 = 6$$
$$N = 9 - 6 = 3$$

Using Eq. 7.33,

$$\mathbf{R} = 4\mathbf{i} + 6\mathbf{j} + 3\mathbf{k}$$

(b) The distance between the two points is

$$d = \sqrt{(4)^2 + (6)^2 + (3)^2} = 7.81$$

The line in terms of its direction cosines is

$$\mathbf{R} = \frac{4\mathbf{i} + 6\mathbf{j} + 3\mathbf{k}}{7.81}$$
$$= 0.512\mathbf{i} + 0.768\mathbf{j} + 0.384\mathbf{k}$$

12. INTERSECTION OF TWO LINES

The intersection of two lines is a point. The location of the intersection point can be determined by setting the two equations equal and solving them in terms of a common variable. Alternatively, Eqs. 7.34 and 7.35 can be used to calculate the coordinates of the intersection point.

$$x = \frac{B_2C_1 - B_1C_2}{A_2B_1 - A_1B_2} \qquad 7.34$$

$$y = \frac{A_1C_2 - A_2C_1}{A_2B_1 - A_1B_2} \qquad 7.35$$

13. PLANES

A *plane* in three-dimensional space is completely determined by one of the following:

- three noncollinear points
- two nonparallel vectors $\mathbf{V}_1$ and $\mathbf{V}_2$ and their intersection point P_0
- a point P_0 and a vector, $\mathbf{N}$, normal to the plane (i.e., the *normal vector*)

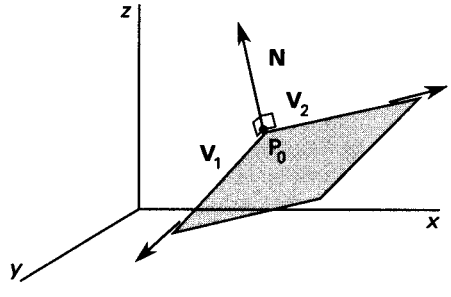

Figure 7.9 *Plane in Three-Dimensional Space*

The plane can be specified mathematically in one of two ways: in rectangular form or as a parametric equation. The general form is

$$A(x - x_0) + B(y - y_0) + C(z - z_0) = 0 \qquad 7.36$$

x_0, y_0, and z_0 are the coordinates of the intersection point of any two vectors in the plane. The coefficients A, B, and C are the same as the coefficients of the normal vector, $\mathbf{N}$.

$$\mathbf{N} = \mathbf{V}_1 \times \mathbf{V}_2 = A\mathbf{i} + B\mathbf{j} + C\mathbf{k} \qquad 7.37$$

Equation 7.36 can be simplified as follows.

$$Ax + By + Cz + D = 0 \qquad 7.38$$

$$D = -(Ax_0 + By_0 + Cz_0) \qquad 7.39$$

The following procedure can be used to determine the equation of a plane from three noncollinear points, P_1, P_2, and P_3, or from a normal vector and a single point.

step 1: (If the normal vector is known, go to step 3.) Determine the equations of the vectors $\mathbf{V}_1$ and $\mathbf{V}_2$ from two pairs of the points. For example, determine $\mathbf{V}_1$ from points P_1 and P_2, and determine $\mathbf{V}_2$ from P_1 and P_3. Express the vectors in the form $A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$.

$$\mathbf{V}_1 = (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} + (z_2 - z_1)\mathbf{k} \qquad 7.40$$

$$\mathbf{V}_2 = (x_3 - x_1)\mathbf{i} + (y_3 - y_1)\mathbf{j} + (z_3 - z_1)\mathbf{k} \qquad 7.41$$

step 2: Find the normal vector, $\mathbf{N}$, as the cross product of the two vectors.

$$\mathbf{N} = \mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & (x_2 - x_1) & (x_3 - x_1) \\ \mathbf{j} & (y_2 - y_1) & (y_3 - y_1) \\ \mathbf{k} & (z_2 - z_1) & (z_3 - z_1) \end{vmatrix} \qquad 7.42$$

step 3: Write the general equation of the plane in rectangular form (Eq. 7.36) using the coefficients A, B, and C from the normal vector and any one of the three points as P_0.

The parametric equations of a plane also can be written as a linear combination of the components of two vectors in the plane. Referring to Fig. 7.9, the two known vectors are

$$\mathbf{V}_1 = V_{1x}\mathbf{i} + V_{1y}\mathbf{j} + V_{1z}\mathbf{k} \qquad 7.43$$

$$\mathbf{V}_2 = V_{2x}\mathbf{i} + V_{2y}\mathbf{j} + V_{2z}\mathbf{k} \qquad 7.44$$

If s and t are scalars, the coordinates of each point in the plane can be written as Eqs. 7.45 through 7.47. These are the parametric equations of the plane.

$$x = x_0 + sV_{1x} + tV_{2x} \quad 7.45$$

$$y = y_0 + sV_{1y} + tV_{2y} \quad 7.46$$

$$z = z_0 + sV_{1z} + tV_{2z} \quad 7.47$$

Example 7.3

The following points are coplanar.

$$P_1 = (2, 1, -4)$$
$$P_2 = (4, -2, -3)$$
$$P_3 = (2, 3, -8)$$

Determine the equation of the plane in (a) general form and (b) parametric form.

Solution

(a) Use the first two points to find a vector, $\mathbf{V}_1$.

$$\begin{aligned}\mathbf{V}_1 &= (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} + (z_2 - z_1)\mathbf{k} \\ &= (4-2)\mathbf{i} + (-2-1)\mathbf{j} + (-3-(-4))\mathbf{k} \\ &= 2\mathbf{i} - 3\mathbf{j} + 1\mathbf{k}\end{aligned}$$

Similarly, use the first and third points to find $\mathbf{V}_2$.

$$\begin{aligned}\mathbf{V}_2 &= (x_3 - x_1)\mathbf{i} + (y_3 - y_1)\mathbf{j} + (z_3 - z_1)\mathbf{k} \\ &= (2-2)\mathbf{i} + (3-1)\mathbf{j} + (-8-(-4))\mathbf{k} \\ &= 0\mathbf{i} + 2\mathbf{j} - 4\mathbf{k}\end{aligned}$$

From Eq. 7.42, determine the normal vector as a determinant.

$$\mathbf{N} = \begin{vmatrix} \mathbf{i} & 2 & 0 \\ \mathbf{j} & -3 & 2 \\ \mathbf{k} & 1 & -4 \end{vmatrix}$$

Expand the determinant across the top row.

$$\begin{aligned}\mathbf{N} &= \mathbf{i}(12-2) - 2(-4\mathbf{j} - 2\mathbf{k}) \\ &= 10\mathbf{i} + 8\mathbf{j} + 4\mathbf{k}\end{aligned}$$

The rectangular form of the equation of the plane uses the same constants as in the normal vector. Use the first point and write the equation of the plane in the form of Eq. 7.36.

$$(10)(x-2) + (8)(y-1) + (4)(z+4) = 0$$

The three constant terms can be combined by using Eq. 7.39.

$$D = -[(10)(2) + (8)(1) + (4)(-4)] = -12$$

The equation of the plane is

$$10x + 8y + 4z - 12 = 0$$

(b) The parametric equations based on the first point and for any values of s and t are

$$x = 2 + 2s + 0t$$
$$y = 1 - 3s + 2t$$
$$z = -4 + 1s - 4t$$

The scalars s and t are not unique. Two of the three coordinates can also be chosen as the parameters. Dividing the rectangular form of the plane's equation by 4 to isolate z results in an alternate set of parametric equations.

$$x = x$$
$$y = y$$
$$z = 3 - 2.5x - 2y$$

14. DISTANCES BETWEEN GEOMETRIC FIGURES

The smallest distance, d, between various geometric figures is given by the following equations.

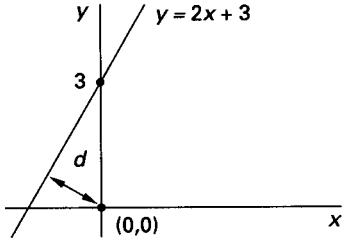
- between two points in (x, y, z) format:

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \quad 7.48$$

- between a point (x_0, y_0) and a line $Ax + By + C = 0$:

$$d = \frac{|Ax_0 + By_0 + C|}{\sqrt{A^2 + B^2}} \quad 7.49$$

- between a point (x_0, y_0, z_0) and a plane $Ax + By + Cz + D = 0$:



$$d = \frac{|Ax_0 + By_0 + Cz_0 + D|}{\sqrt{A^2 + B^2 + C^2}} \quad 7.50$$

- between two parallel lines $Ax + By + C = 0$:

$$d = \left| \frac{|C_2|}{\sqrt{A_2^2 + B_2^2}} - \frac{|C_1|}{\sqrt{A_1^2 + B_1^2}} \right| \quad 7.51$$

Example 7.4

What is the minimum distance between the line $y = 2x + 3$ and the origin $(0, 0)$?

Solution

Put the equation in general form.

$$Ax + By + C = 2x - y + 3 = 0$$

Use Eq. 7.49 with $(x, y) = (0, 0)$.

$$d = \frac{|Ax + By + C|}{\sqrt{A^2 + B^2}} = \frac{(2)(0) + (-1)(0) + 3}{\sqrt{(2)^2 + (-1)^2}}$$
$$= \frac{3}{\sqrt{5}}$$

15. ANGLES BETWEEN GEOMETRIC FIGURES

The angle, ϕ, between various geometric figures is given by the following equations.

- between two lines in $Ax+By+C = 0$, $y = mx+b$, or direction angle formats:

$$\phi = \arctan\left(\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right) \quad 7.52$$

$$= \arctan\left(\frac{m_2 - m_1}{1 + m_1m_2}\right) \quad 7.53$$

$$= |\arctan(m_1) - \arctan(m_2)| \quad 7.54$$

$$= \arccos\left(\frac{L_1L_2 + M_1M_2 + N_1N_2}{d_1d_2}\right) \quad 7.55$$

$$= \arccos(\cos\alpha_1 \cos\alpha_2 + \cos\beta_1 \cos\beta_2 + \cos\gamma_1 \cos\gamma_2) \quad 7.56$$

If the lines are parallel, then $\phi = 0$.

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} \quad 7.57$$

$$m_1 = m_2 \quad 7.58$$

$$\alpha_1 = \alpha_2;\ \beta_1 = \beta_2;\ \gamma_1 = \gamma_2 \quad 7.59$$

If the lines are perpendicular, then $\phi = 90°$.

$$A_1A_2 = -B_1B_2 \quad 7.60$$

$$m_1 = \frac{-1}{m_2} \quad 7.61$$

$$\alpha_1 + \alpha_2 = \beta_1 + \beta_2 = \gamma_1 + \gamma_2 = 90° \quad 7.62$$

- between two planes in $A\mathbf{i} + B\mathbf{j} + C\mathbf{k} = 0$ format, the coefficients A, B, and C are the same as the coefficients for the normal vector. (See Eq. 7.37.) ϕ is equal to the angle between the two normal vectors.

$$\cos\phi = \frac{|A_1A_2 + B_1B_2 + C_1C_2|}{\sqrt{A_1^2 + B_1^2 + C_1^2}\sqrt{A_2^2 + B_2^2 + C_2^2}} \quad 7.63$$

Example 7.5

Use Eqs. 7.52, 7.53, and 7.54 to find the angle between the lines.

$$y = -0.577x + 2$$
$$y = +0.577x - 5$$

Solution

Write both equations in general form.

$$-0.577x - y + 2 = 0$$
$$0.577x - y - 5 = 0$$

(a) From Eq. 7.52,

$$\phi = \arctan\left(\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right)$$
$$= \arctan\left(\frac{(-0.577)(-1) - (0.577)(-1)}{(-0.577)(0.577) + (-1)(-1)}\right) = 60°$$

(b) Use Eq. 7.53.

$$\phi = \arctan\left(\frac{m_2 - m_1}{1 + m_1m_2}\right)$$
$$= \arctan\left(\frac{0.577 - (-0.577)}{1 + (0.577)(-0.577)}\right) = 60°$$

(c) Use Eq. 7.54.

$$\phi = |\arctan(m_1) - \arctan(m_2)|$$
$$= |\arctan(-0.577) - \arctan(0.577)|$$
$$= |-30° - 30°| = 60°$$

16. CONIC SECTIONS

A *conic section* is any one of several curves produced by passing a plane through a cone as shown in Fig. 7.10. If α is the angle between the vertical axis and the cutting plane and β is the cone generating angle, Eq. 7.64 gives the *eccentricity*, ϵ, of the conic section. Values of the eccentricity are given in Fig. 7.10.

$$\epsilon = \frac{\cos\alpha}{\cos\beta} \quad 7.64$$

All conic sections are described by second-degree polynomials (i.e., are *quadratic equations*) of the following form.[5]

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0 \quad 7.65$$

[5]One or more straight lines are produced when the cutting plane passes through the cone's vertex. Straight lines can be considered to be quadratic functions without second-degree terms.

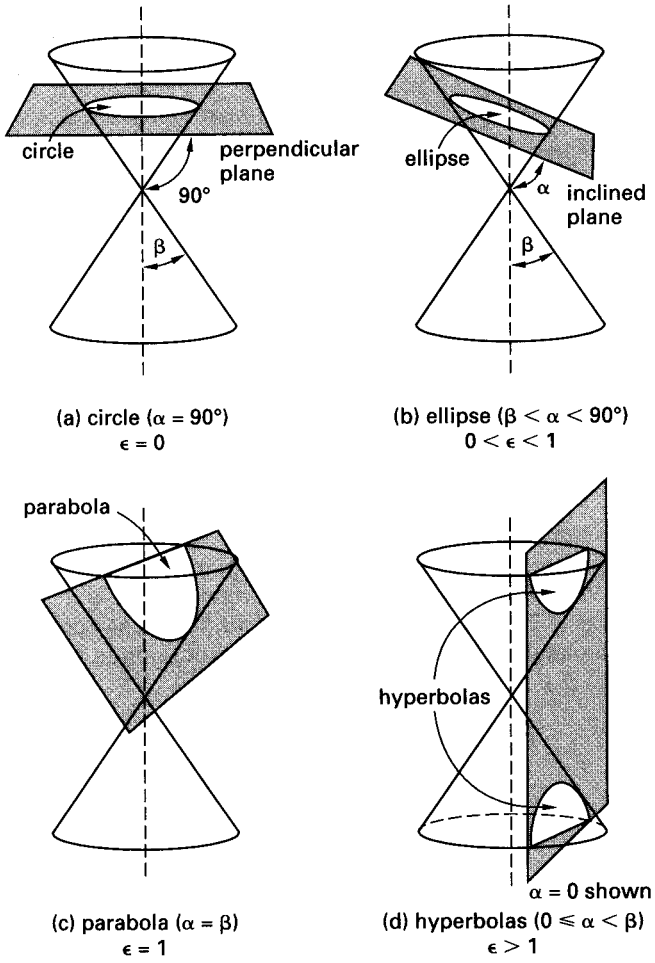


Figure 7.10 *Conic Sections Produced by Cutting Planes*

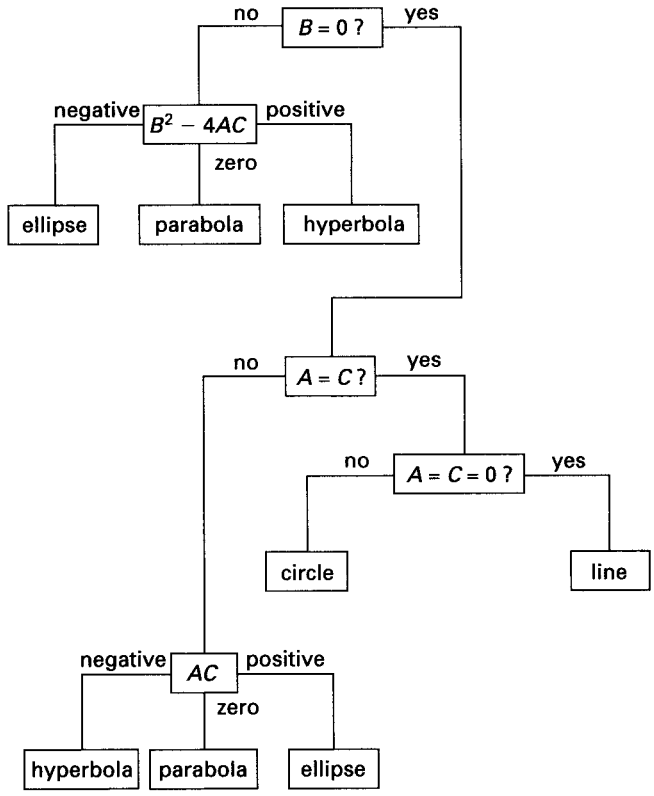

Figure 7.11 *Determining Conic Sections from Quadratic Equations*

This is the *general form*, which allows the figure axes to be at any angle relative to the coordinate axes. The *standard forms* presented in the following sections pertain to figures whose axes coincide with the coordinate axes, thereby eliminating certain terms of the general equation.

Figure 7.11 can be used to determine which conic section is described by the quadratic function. The quantity B^2-4AC is known as the *discriminant*. Figure 7.11 determines only the type of conic section; it does not determine whether the conic section is degenerate (e.g., a circle with a negative radius).

Example 7.6

What geometric figures are described by the following equations?

(a) $4y^2 - 12y + 16x + 41 = 0$

(b) $x^2 - 10xy + y^2 + x + y + 1 = 0$

(c) $x^2 + 4y^2 + 2x - 8y + 1 = 0$

(d) $x^2 + y^2 - 6x + 8y + 20 = 0$

Solution

(a) Referring to Fig. 7.11, $B = 0$ since there is no xy term, $A = 0$ since there is no x^2 term, and $AC = (0)(4) = 0$. This is a parabola.

(b) $B \neq 0$; $B^2 - 4AC = (-10)^2 - (4)(1)(1) = +96$. This is a hyperbola.

(c) $B = 0$; $A \neq C$; $AC = (1)(4) = +4$. This is an ellipse.

(d) $B = 0$; $A = C$; $A = C = 1$ $(\neq 0)$. This is a circle.

17. CIRCLE

The general form of the equation of a circle is

$$Ax^2 + Ay^2 + Dx + Ey + F = 0 \qquad 7.66$$

The *center-radius form* of the equation of a circle with radius r and center at (h, k) is

$$(x - h)^2 + (y - k)^2 = r^2 \qquad 7.67$$

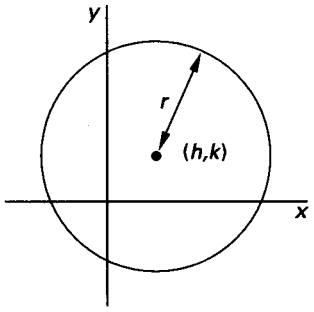

Figure 7.12 *Circle*

The two forms can be converted by use of Eqs. 7.68 through 7.70.

$$h = \frac{-D}{2A} \qquad 7.68$$

$$k = \frac{-E}{2A} \qquad 7.69$$

$$r^2 = \frac{D^2 + E^2 - 4AF}{4A^2} \qquad 7.70$$

If the right-hand side of Eq. 7.70 is positive, the figure is a circle. If it is zero, the circle shrinks to a point. If the right-hand side is negative, the figure is imaginary. A *degenerate circle* is one in which the right-hand side is less than or equal to zero.

18. PARABOLA

A *parabola* is the locus of points equidistant from the *focus* (point F in Fig. 7.13) and a line called the *directrix*. A parabola is symmetric with respect to its *parabolic axis*. The line normal to the parabolic axis and passing through the focus is known as the *latus rectum*. The eccentricity of a parabola is 1.

There are two common types of parabolas in the Cartesian plane—those that open right and left, and those that open up and down. Equation 7.65 is the general form of the equation of a parabola. With Eq. 7.71, the parabola points to the right if $CD > 0$ and to the left if $CD < 0$. With Eq. 7.72, the parabola points up if $AE > 0$ and down if $AE < 0$.

$$Cy^2 + Dx + Ey + F = 0 \quad \Big|_{\substack{C,D \neq 0 \\ \text{opens horizontally}}} \qquad 7.71$$

$$Ax^2 + Dx + Ey + F = 0 \quad \Big|_{\substack{A,E \neq 0 \\ \text{opens vertically}}} \qquad 7.72$$

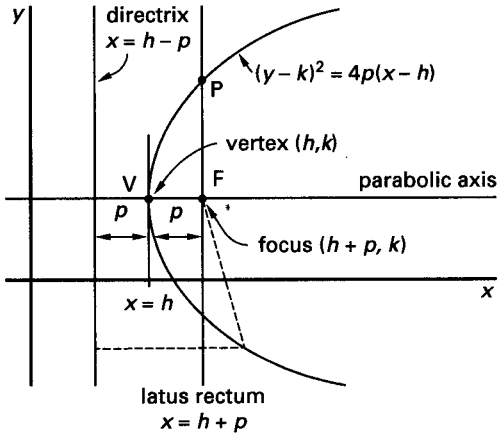

Figure 7.13 *Parabola*

The *standard form* of the equation of a parabola with vertex at (h, k), focus at $(h + p, k)$, and directrix at $x = h - p$ and that opens to the right or left is given by Eq. 7.73. The parabola opens to the right (points to the left) if $p > 0$ and opens to the left (points to the right) if $p < 0$.

$$(y - k)^2 = 4p(x - h) \quad \Big|_{\text{opens horizontally}} \qquad 7.73$$

$$y^2 = 4px \quad \Big|_{\substack{\text{vertex at origin} \\ h = k = 0}} \qquad 7.74$$

The *standard form* of the equation of a parabola with vertex at (h, k), focus at $(h, k + p)$, and directrix at $y = k - p$ and that opens up or down is given by Eq. 7.75. The parabola opens up (points down) if $p > 0$ and opens down (points up) if $p < 0$.

$$(x - h)^2 = 4p(y - k) \quad \Big|_{\text{opens vertically}} \qquad 7.75$$

$$x^2 = 4py \quad \Big|_{\text{vertex at origin}} \qquad 7.76$$

The general and vertex forms of the equations can be reconciled with Eqs. 7.77 through 7.79. Whether the first or second forms of these equations are used depends on whether the parabola opens horizontally or vertically (i.e., whether $A = 0$ or $C = 0$), respectively.

$$h = \begin{cases} \dfrac{E^2 - 4CF}{4CD} & \text{[opens horizontally]} \\ \dfrac{-D}{2A} & \text{[opens vertically]} \end{cases} \qquad 7.77$$

$$k = \begin{cases} \dfrac{-E}{2C} & \text{[opens horizontally]} \\ \dfrac{D^2 - 4AF}{4AE} & \text{[opens vertically]} \end{cases} \qquad 7.78$$

$$p = \begin{cases} \dfrac{-D}{4C} & \text{[opens horizontally]} \\ \dfrac{-E}{4A} & \text{[opens vertically]} \end{cases} \qquad 7.79$$

19. ELLIPSE

An *ellipse* has two foci separated along the *major axis* by a distance $2c$. The line perpendicular to the major axis passing through the center of the ellipse is the *minor axis*. The lines perpendicular to the major axis passing through the foci are the *latus recta*. The distance between the two vertices is $2a$. The ellipse is the locus of points such that the sum of the distances from the two foci is $2a$. Referring to Fig. 7.14,

$$F_1P + PF_2 = 2a \qquad 7.80$$

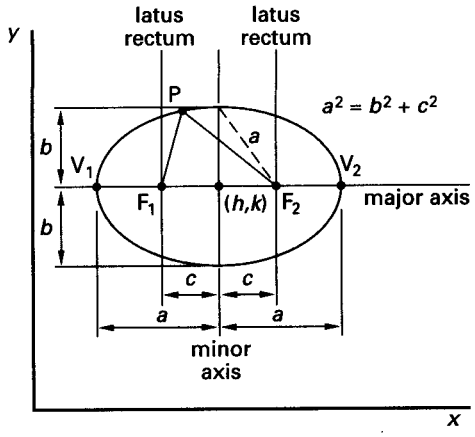

Figure 7.14 *Ellipse*

Equation 7.81 is the standard equation for an ellipse with axes parallel to the coordinate axes. (Equation 7.65 is the general form.) F is not independent of A, C, D, and E for the ellipse.

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \Big|_{\substack{AC > 0 \\ A \neq C}} \qquad 7.81$$

Equation 7.82 gives the standard form of the equation of an ellipse centered at (h, k). Distances a and b are known as the *semimajor distance* and *semiminor distance*, respectively.

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1 \qquad 7.82$$

The distance between the two foci is $2c$.

$$2c = 2\sqrt{a^2 - b^2} \qquad 7.83$$

The *aspect ratio* of the ellipse is

$$\text{aspect ratio} = \frac{a}{b} \qquad 7.84$$

The *eccentricity*, ϵ, of the ellipse is always less than 1. If the eccentricity is zero, the figure is a circle (another form of a *degenerative ellipse*).

$$\epsilon = \frac{\sqrt{a^2 - b^2}}{a} < 1 \qquad 7.85$$

The standard and center forms of the equations of an ellipse can be reconciled by using Eqs. 7.86 through 7.89.

$$h = \frac{-D}{2A} \qquad 7.86$$

$$k = \frac{-E}{2C} \qquad 7.87$$

$$a = \sqrt{C} \qquad 7.88$$

$$b = \sqrt{A} \qquad 7.89$$

20. HYPERBOLA

A *hyperbola* has two foci separated along the *transverse axis* by a distance $2c$. Lines perpendicular to the transverse axis passing through the foci are the *conjugate axes*. The distance between the two vertices is $2a$, and the distance along a conjugate axis between two points on the hyperbola is $2b$. The hyperbola is the locus of points such that the difference in distances from the two foci is $2a$. Referring to Fig. 7.15,

$$F_2P - PF_1 = 2a \qquad 7.90$$

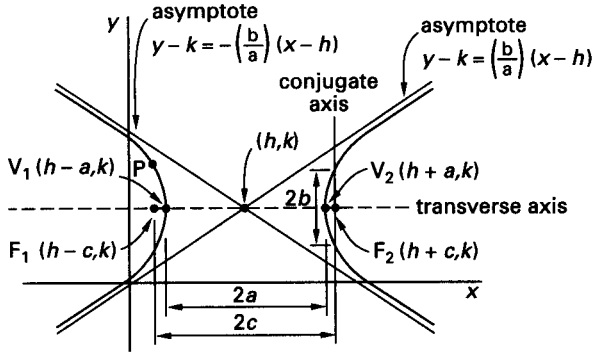

Figure 7.15 *Hyperbola*

Equation 7.91 is the standard equation of a hyperbola. Coefficients A and C have opposite signs.

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \big|_{AC < 0} \qquad 7.91$$

Equation 7.92 gives the standard form of the equation of a hyperbola centered at (h, k) and opening to the left and right.

$$\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1 \Big|_{\text{opens horizontally}} \qquad 7.92$$

Equation 7.93 gives the standard form of the equation of a hyperbola centered at (h, k) and opening up and down.

$$\frac{(y-k)^2}{a^2} - \frac{(x-h)^2}{b^2} = 1 \Big|_{\text{opens vertically}} \qquad 7.93$$

The distance between the two foci is $2c$.

$$2c = 2\sqrt{a^2 + b^2} \qquad 7.94$$

The *eccentricity*, ϵ, of the hyperbola is calculated from Eq. 7.95 and is always greater than 1.

$$\epsilon = \frac{c}{a} = \frac{\sqrt{a^2 + b^2}}{a} > 1 \qquad 7.95$$

The hyperbola is asymptotic to the lines given by Eqs. 7.96 and 7.97.

$$y = \pm\frac{b}{a}(x - h) + k \Big|_{\text{opens horizontally}} \qquad 7.96$$

$$y = \pm\frac{a}{b}(x - h) + k \Big|_{\text{opens vertically}} \qquad 7.97$$

For a *rectangular* (*equilateral*) *hyperbola*, the asymptotes are perpendicular, $a = b$, $c = \sqrt{2}a$, and the eccentricity is $\epsilon = \sqrt{2}$. If the hyperbola is centered at the origin (i.e., $h = k = 0$), then the equations are $x^2 - y^2 = a^2$ (opens horizontally) and $y^2 - x^2 = a^2$ (opens vertically).

If the asymptotes are the x- and y-axes, the equation of the hyperbola is simply

$$xy = \pm\frac{a^2}{2} \qquad 7.98$$

The general and center forms of the equations of a hyperbola can be reconciled by using Eqs. 7.99 through 7.103. Whether the hyperbola opens left and right or up and down depends on whether M/A or M/C is positive, respectively, where M is defined by Eq. 7.99.

$$M = \frac{D^2}{4A} + \frac{E^2}{4C} - F \qquad 7.99$$

$$h = \frac{-D}{2A} \qquad 7.100$$

$$k = \frac{-E}{2C} \qquad 7.101$$

$$a = \begin{cases} \sqrt{-C} & \text{[opens horizontally]} \\ \sqrt{-A} & \text{[opens vertically]} \end{cases} \qquad 7.102$$

$$b = \begin{cases} \sqrt{A} & \text{[opens horizontally]} \\ \sqrt{C} & \text{[opens vertically]} \end{cases} \qquad 7.103$$

21. SPHERE

Equation 7.104 is the general equation of a sphere. The coefficient A cannot be zero.

$$Ax^2 + Ay^2 + Az^2 + Bx + Cy + Dz + E = 0 \qquad 7.104$$

Equation 7.105 gives the standard form of the equation of a sphere centered at (h, k, l) with radius r.

$$(x - h)^2 + (y - k)^2 + (z - l)^2 = r^2 \qquad 7.105$$

The general and center forms of the equations of a sphere can be reconciled by using Eqs. 7.106 through 7.109.

$$h = \frac{-B}{2A} \qquad 7.106$$

$$k = \frac{-C}{2A} \qquad 7.107$$

$$l = \frac{-D}{2A} \qquad 7.108$$

$$r = \sqrt{\frac{B^2 + C^2 + D^2}{4A^2} - \frac{E}{A}} \qquad 7.109$$

Planes tangent to spheres and other solids are covered in Chap. 8, Sec. 7.

22. HELIX

A *helix* is a curve generated by a point moving on, around, and along a cylinder such that the distance the point moves parallel to the cylindrical axis is proportional to the angle of rotation about that axis. For a cylinder of radius r, Eqs. 7.110 through 7.112 define the three-dimensional positions of points along the helix. The quantity $2\pi k$ is the *pitch* of the helix.

$$x = r\cos\theta \qquad 7.110$$

$$y = r\sin\theta \qquad 7.111$$

$$z = k\theta \qquad 7.112$$

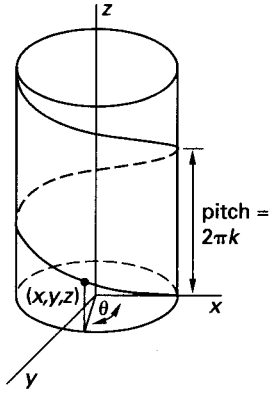

Figure 7.16 *Helix*

PRACTICE PROBLEMS

1. The diameter of a sphere and the base of a cone are equal. What percentage of that diameter must the cone's height be so that both volumes are equal?

(A) 133%
(B) 150%
(C) 166%
(D) 200%

The answer is (D).

1. DERIVATIVE OF A FUNCTION

In most cases, it is possible to transform a continuous function, $f(x_1, x_2, x_3, \ldots)$, of one or more independent variables into a derivative function.[1] In simple cases, the *derivative* can be interpreted as the slope (tangent or rate of change) of the curve described by the original function. Since the slope of the curve depends on x, the derivative function will also depend on x. The derivative, $f'(x)$, of a function $f(x)$ is defined mathematically by Eq. 8.1. However, limit theory is seldom needed to actually calculate derivatives.

$$f'(x) = \lim_{\Delta x \to 0} \frac{\Delta f(x)}{\Delta x} \tag{8.1}$$

The derivative of a function $f(x)$, also known as the *first derivative*, is written in various ways, including

$$f'(x), \frac{df(x)}{dx}, \frac{df}{dx}, \mathbf{D}f(x), \mathbf{D}_x f(x), \dot{f}(x), sf(x)$$

A *second derivative* may exist if the derivative operation is performed on the first derivative—that is, a derivative is taken of a derivative function. This is written as

$$f''(x), \frac{d^2 f(x)}{dx^2}, \frac{d^2 f}{dx^2}, \mathbf{D}^2 f(x), \mathbf{D}_x^2 f(x), \ddot{f}(x), s^2 f(x)$$

[1] A function, $f(x)$, of one independent variable, x, is used in this section to simplify the discussion. Although the derivative is taken with respect to x, the independent variable can be anything.

A *regular* (*analytic* or *holomorphic*) *function* possesses a derivative. A point at which a function's derivative is undefined is called a *singular point*, as Fig. 8.1 illustrates.

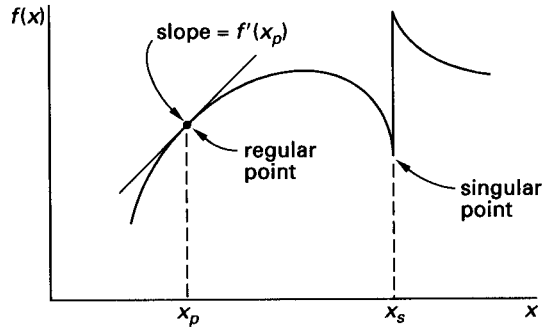

Figure 8.1 *Derivatives and Singular Points*

2. ELEMENTARY DERIVATIVE OPERATIONS

Equations 8.2 through 8.5 summarize the elementary derivative operations on polynomials and exponentials. Equations 8.2 and 8.3 are particularly useful. (a, n, and k represent constants. $f(x)$ and $g(x)$ are functions of x.)

$$\mathbf{D}k = 0 \tag{8.2}$$

$$\mathbf{D}x^n = nx^{n-1} \tag{8.3}$$

$$\mathbf{D} \ln x = \frac{1}{x} \tag{8.4}$$

$$\mathbf{D}e^{ax} = ae^{ax} \tag{8.5}$$

Equations 8.6 through 8.17 summarize the elementary derivative operations on transcendental (trigonometric) functions.

$$\mathbf{D} \sin x = \cos x \tag{8.6}$$

$$\mathbf{D} \cos x = -\sin x \tag{8.7}$$

$$\mathbf{D} \tan x = \sec^2 x \tag{8.8}$$

$$\mathbf{D} \cot x = -\csc^2 x \tag{8.9}$$

$$\mathbf{D} \sec x = \sec x \tan x \tag{8.10}$$

$$\mathbf{D} \csc x = -\csc x \cot x \tag{8.11}$$

$$\mathbf{D} \arcsin x = \frac{1}{\sqrt{1-x^2}} \tag{8.12}$$

$$\mathbf{D}\arccos x = -\mathbf{D}\arcsin x \qquad 8.13$$

$$\mathbf{D}\arctan x = \frac{1}{1+x^2} \qquad 8.14$$

$$\mathbf{D}\operatorname{arccot} x = -\mathbf{D}\arctan x \qquad 8.15$$

$$\mathbf{D}\operatorname{arcsec} x = \frac{1}{x\sqrt{x^2-1}} \qquad 8.16$$

$$\mathbf{D}\operatorname{arccsc} x = -\mathbf{D}\operatorname{arcsec} x \qquad 8.17$$

Equations 8.18 through 8.23 summarize the elementary derivative operations on hyperbolic transcendental functions. Derivatives of hyperbolic functions are not completely analogous to those of the regular transcendental functions.

$$\mathbf{D}\sinh x = \cosh x \qquad 8.18$$

$$\mathbf{D}\cosh x = \sinh x \qquad 8.19$$

$$\mathbf{D}\tanh x = \operatorname{sech}^2 x \qquad 8.20$$

$$\mathbf{D}\coth x = -\operatorname{csch}^2 x \qquad 8.21$$

$$\mathbf{D}\operatorname{sech} x = -\operatorname{sech} x \tanh x \qquad 8.22$$

$$\mathbf{D}\operatorname{csch} x = -\operatorname{csch} x \coth x \qquad 8.23$$

Equations 8.24 through 8.29 summarize the elementary derivative operations on functions and combinations of functions.

$$\mathbf{D}kf(x) = k\mathbf{D}f(x) \qquad 8.24$$

$$\mathbf{D}(f(x) \pm g(x)) = \mathbf{D}f(x) \pm \mathbf{D}g(x) \qquad 8.25$$

$$\mathbf{D}(f(x) \cdot g(x)) = f(x)\mathbf{D}g(x) + g(x)\mathbf{D}f(x) \qquad 8.26$$

$$\mathbf{D}\left(\frac{f(x)}{g(x)}\right) = \frac{g(x)\mathbf{D}f(x) - f(x)\mathbf{D}g(x)}{(g(x))^2} \qquad 8.27$$

$$\mathbf{D}\,(f(x))^n = n\,(f(x))^{n-1}\,\mathbf{D}f(x) \qquad 8.28$$

$$\mathbf{D}f(g(x)) = \mathbf{D}_g f(g)\mathbf{D}_x g(x) \qquad 8.29$$

Example 8.1

What is the slope at $x = 3$ of the curve $f(x) = x^3 - 2x$?

Solution

The derivative function found from Eq. 8.3 determines the slope.

$$f'(x) = 3x^2 - 2$$

The slope at $x = 3$ is

$$f'(3) = (3)(3)^2 - 2 = 27 - 2 = 25$$

Example 8.2

What are the derivatives of the following functions?

(a) $f(x) = 5\sqrt[3]{x^5}$

(b) $f(x) = \sin x \cos^2 x$

(c) $f(x) = ln(\cos e^x)$

Solution

(a) Using Eqs. 8.3 and 8.24,

$$\begin{aligned} f'(x) = 5\mathbf{D}\sqrt[3]{x^5} &= 5\mathbf{D}\left[(x^5)^{\frac{1}{3}}\right] \\ &= (5)\left(\tfrac{1}{3}\right)(x^5)^{-\frac{2}{3}}\mathbf{D}x^5 \\ &= (5)\left(\tfrac{1}{3}\right)(x^5)^{-\frac{2}{3}}(5)(x^4) \\ &= \frac{25\,x^{\frac{2}{3}}}{3} \end{aligned}$$

(b) Using Eq. 8.26,

$$\begin{aligned} f'(x) &= \sin x\mathbf{D}\cos^2 x + \cos^2 x\mathbf{D}\sin x \\ &= (\sin x)(2\cos x)(\mathbf{D}\cos x) + \cos^2 x\cos x \\ &= (\sin x)(2\cos x)(-\sin x) + \cos^2 x\cos x \\ &= -2\sin^2 x\cos x + \cos^3 x \end{aligned}$$

(c) Using Eq. 8.29,

$$\begin{aligned} f'(x) &= \left(\frac{1}{\cos e^x}\right)\mathbf{D}\cos e^x \\ &= \left(\frac{1}{\cos e^x}\right)(-\sin e^x)\mathbf{D}e^x \\ &= \left(\frac{-\sin e^x}{\cos e^x}\right)e^x \\ &= -e^x \tan e^x \end{aligned}$$

3. CRITICAL POINTS

Derivatives are used to locate the local *critical points* of functions of one variable—that is, *extreme points* (also known as *maximum* and *minimum* points) as well as the *inflection points* (*points of contraflexure*). The plurals *extrema*, *maxima*, and *minima* are used without the word "points." These points are illustrated in Fig. 8.2. There is usually an inflection point between two adjacent local extrema.

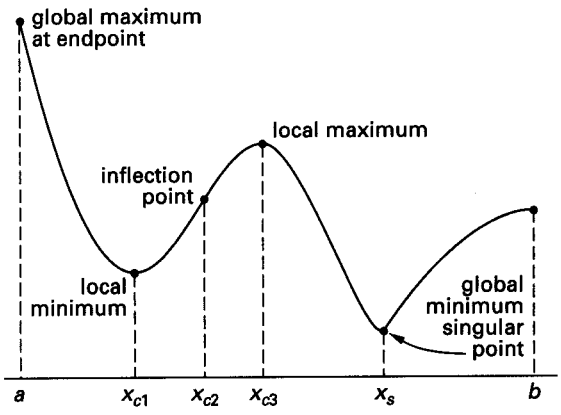

Figure 8.2 *Extreme and Inflection Points*

The first derivative is calculated to determine the locations of the critical points. The second derivative is calculated to determine whether a critical point is a local maximum, minimum, or inflection point, according to the following conditions. With this method, no distinction is made between local and global extrema. Therefore, the extrema should be compared with the function values at the endpoints of the interval, as illustrated in Ex. 8.3.[2] Note that $f'(x) \neq 0$ at an inflection point.

$$f'(x_c) = 0 \text{ at any extreme point, } x_c \qquad 8.30$$

$$f''(x_c) < 0 \text{ at a maximum point} \qquad 8.31$$

$$f''(x_c) > 0 \text{ at a minimum point} \qquad 8.32$$

$$f''(x_c) = 0 \text{ at an inflection point} \qquad 8.33$$

Example 8.3

Find the global extrema of the function $f(x)$ on the interval $[-2, +2]$.

$$f(x) = x^3 + x^2 - x + 1$$

Solution

The first derivative is

$$f'(x) = 3x^2 + 2x - 1$$

Since the first derivative is zero at extreme points, set $f'(x)$ equal to zero and solve for the roots of the quadratic equation.

$$3x^2 + 2x - 1 = (3x - 1)(x + 1) = 0$$

The roots are $x_1 = 1/3$, $x_2 = -1$. These are the locations of the two extrema.

[2]It is also necessary to check the values of the function at singular points (i.e., points where the derivative does not exist).

The second derivative is

$$f''(x) = 6x + 2$$

Substituting x_1 and x_2 into $f''(x)$,

$$f''(x_1) = (6)\left(\tfrac{1}{3}\right) + 2 = 4$$

$$f''(x_2) = (6)(-1) + 2 = -4$$

Therefore, x_1 is a local minimum point (because $f''(x)$ is positive), and x_2 is a local maximum point (because $f''(x)$ is negative). The inflection point between these two extrema is found by setting $f''(x)$ equal to zero.

$$f''(x) = 6x + 2 = 0 \text{ or } x = -\tfrac{1}{3}$$

Since the question asked for the global extreme points, it is necessary to compare the values of $f(x)$ at the local extrema with the values at the endpoints.

$$f(-2) = -1$$

$$f(-1) = 2$$

$$f\left(\tfrac{1}{3}\right) = 22/27$$

$$f(2) = +11$$

Therefore, the actual global extrema are the endpoints.

4. DERIVATIVES OF PARAMETRIC EQUATIONS

The derivative of a function $f(x_1, x_2, \ldots x_n)$ can be calculated from the derivatives of the parametric equations $f_1(s), f_2(s), \ldots, f_n(s)$. The derivative will be expressed in terms of the parameter, s, unless the derivatives of the parametric equations can be expressed explicitly in terms of the independent variables.

Example 8.4

A circle is expressed parametrically by the equations

$$x = 5\cos\theta$$

$$y = 5\sin\theta$$

Express the derivative dy/dx (a) as a function of the parameter θ and (b) as a function of x and y.

Solution

(a) Taking the derivative of each parametric equation with respect to θ,

$$\frac{dx}{d\theta} = -5\sin\theta$$

$$\frac{dy}{d\theta} = 5\cos\theta$$

Then,

$$\frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} = \frac{5\cos\theta}{-5\sin\theta} = -\cot\theta$$

(b) The derivatives of the parametric equations are closely related to the original parametric equations.

$$\frac{dx}{d\theta} = -5\sin\theta = -y$$

$$\frac{dy}{d\theta} = 5\cos\theta = x$$

$$\frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} = \frac{-x}{y}$$

5. PARTIAL DIFFERENTIATION

Derivatives can be taken with respect to only one independent variable at a time. For example, $f'(x)$ is the derivative of $f(x)$ and is taken with respect to the independent variable x. If a function, $f(x_1, x_2, x_3, \ldots)$, has more than one independent variable, a *partial derivative* can be found, but only with respect to one of the independent variables. All other variables are treated as constants. Symbols for a partial derivative of f taken with respect to variable x are $\partial f/\partial x$ and $f_x(x,y)$.

The geometric interpretation of a partial derivative $\partial f/\partial x$ is the slope of a line tangent to the surface (a sphere, ellipsoid, etc.) described by the function when all variables except x are held constant. In three-dimensional space with a function described by $z = f(x,y)$, the partial derivative $\partial f/\partial x$ (equivalent to $\partial z/\partial x$) is the slope of the line tangent to the surface in a plane of constant y. Similarly, the partial derivative $\partial f/\partial y$ (equivalent to $\partial z/\partial y$) is the slope of the line tangent to the surface in a plane of constant x.

Example 8.5

What is the partial derivative $\partial z/\partial x$ of the following function?

$$z = 3x^2 - 6y^2 + xy + 5y - 9$$

Solution

The partial derivative with respect to x is found by considering all variables other than x to be constants.

$$\frac{\partial z}{\partial x} = 6x - 0 + y + 0 - 0 = 6x + y$$

Example 8.6

A surface has the equation $x^2 + y^2 + z^2 - 9 = 0$. What is the slope of a line that lies in a plane of constant y and is tangent to the surface at $(x,y,z) = (1,2,2)$?[3]

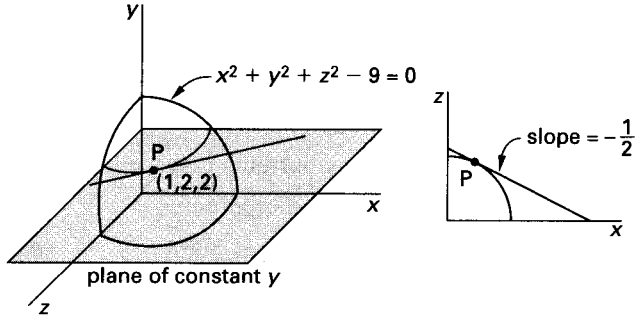
[3]Although only implied, it is required that the point actually be on the surface (i.e., it must satisfy the equation $f(x,y,z) = 0$).

Solution

Solve for the dependent variable. Then, consider variable y to be a constant.

$$z = \sqrt{9 - x^2 - y^2}$$

$$\frac{\partial z}{\partial x} = \frac{\partial (9 - x^2 - y^2)^{\frac{1}{2}}}{\partial x}$$



$$= \left(\tfrac{1}{2}\right)(9 - x^2 - y^2)^{-\frac{1}{2}}\left[\frac{\partial(9 - x^2 - y^2)}{\partial x}\right]$$

$$= \left(\tfrac{1}{2}\right)(9 - x^2 - y^2)^{-\frac{1}{2}}(-2x)$$

$$= \frac{-x}{\sqrt{9 - x^2 - y^2}}$$

At the point $(1,2,2)$, $x = 1$ and $y = 2$.

$$\left.\frac{\partial z}{\partial x}\right|_{(1,2,2)} = \frac{-1}{\sqrt{9 - (1)^2 - (2)^2}} = -\tfrac{1}{2}$$

6. IMPLICIT DIFFERENTIATION

When a relationship between n variables cannot be manipulated to yield an explicit function of $n-1$ independent variables, that relationship implicitly defines the nth variable. Finding the derivative of the implicit variable with respect to any other independent variable is known as *implicit differentiation*.

An implicit derivative is the quotient of two partial derivatives. The two partial derivatives are chosen so that dividing one by the other eliminates a common differential. For example, if z cannot be explicitly extracted from $f(x,y,z) = 0$, the partial derivatives $\partial z/\partial x$ and $\partial z/\partial y$ can still be found as follows.

$$\frac{\partial z}{\partial x} = \frac{-\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial z}} \qquad 8.34$$

$$\frac{\partial z}{\partial y} = \frac{-\frac{\partial f}{\partial y}}{\frac{\partial f}{\partial z}} \qquad 8.35$$

Example 8.7

Find the derivative dy/dx of

$$f(x,y) = x^2 + xy + y^3$$

Solution

Implicit differentiation is required because x cannot be extracted from $f(x,y)$.

$$\frac{\partial f}{\partial x} = 2x + y$$

$$\frac{\partial f}{\partial y} = x + 3y^2$$

$$\frac{dy}{dx} = \frac{-\dfrac{\partial f}{\partial x}}{\dfrac{\partial f}{\partial y}} = \frac{-(2x+y)}{x+3y^2}$$

Example 8.8

Solve Ex. 8.6 using implicit differentiation.

Solution

$$f(x,y,z) = x^2 + y^2 + z^2 - 9 = 0$$

$$\frac{\partial f}{\partial x} = 2x$$

$$\frac{\partial f}{\partial z} = 2z$$

$$\frac{\partial z}{\partial x} = \frac{-\dfrac{\partial f}{\partial x}}{\dfrac{\partial f}{\partial z}} = \frac{-2x}{2z} = -\frac{x}{z}$$

At the point $(1,2,2)$,

$$\frac{\partial z}{\partial x} = -\tfrac{1}{2}$$

7. TANGENT PLANE FUNCTION

Partial derivatives can be used to find the equation of a plane tangent to a three-dimensional surface defined by $f(x,y,z) = 0$ at some point, P_0.

$$\begin{aligned} T(x_0,y_0,z_0) &= (x-x_0)\frac{\partial f(x,y,z)}{\partial x}\Big|_{P_0} \\ &\quad + (y-y_0)\frac{\partial f(x,y,z)}{\partial y}\Big|_{P_0} \\ &\quad + (z-z_0)\frac{\partial f(x,y,z)}{\partial z}\Big|_{P_0} \\ &= 0 \end{aligned} \qquad 8.36$$

The coefficients of x, y, and z are the same as the coefficients of **i**, **j**, and **k** of the normal vector at point P_0. (See Secs. 7.13 and 8.10.)

Example 8.9

What is the equation of the plane that is tangent to the surface defined by $f(x,y,z) = 4x^2 + y^2 - 16z = 0$ at the point $(2,4,2)$?

Solution

First, calculate the partial derivatives and substitute the coordinates of the point.

$$\frac{\partial f(x,y,z)}{\partial x}\Big|_{P_0} = 8x|_{(2,4,2)} = (8)(2) = 16$$

$$\frac{\partial f(x,y,z)}{\partial y}\Big|_{P_0} = 2y|_{(2,4,2)} = (2)(4) = 8$$

$$\frac{\partial f(x,y,z)}{\partial z}\Big|_{P_0} = -16|_{(2,4,2)} = -16$$

$$\begin{aligned} T(2,4,2) &= (16)(x-2) + (8)(y-4) - (16)(z-2) \\ &= 2x + y - 2z - 4 \end{aligned}$$

Next, substitute into Eq. 8.36.

$$2x + y - 2z - 4 = 0$$

8. GRADIENT VECTOR

The slope of a function is the change in one variable with respect to a distance in a chosen direction. Usually, the direction is parallel to a coordinate axis. However, the maximum slope at a point on a surface may not be in a direction parallel to one of the coordinate axes.

The *gradient vector function* $\nabla f(x,y,z)$ (pronounced "del f") gives the maximum rate of change of the function $f(x,y,z)$.

$$\begin{aligned} \nabla f(x,y,z) &= \left(\frac{\partial f(x,y,z)}{\partial x}\right)\mathbf{i} + \left(\frac{\partial f(x,y,z)}{\partial y}\right)\mathbf{j} \\ &\quad + \left(\frac{\partial f(x,y,z)}{\partial z}\right)\mathbf{k} \end{aligned} \qquad 8.37$$

Example 8.10

A two-dimensional function is defined as

$$f(x,y) = 2x^2 - y^2 + 3x - y$$

(a) What is the gradient vector for this function? (b) What is the direction of the line passing through the point $(1,-2)$ that has a maximum slope? (c) What is the maximum slope at the point $(1,-2)$?

Solution

(a) It is necessary to calculate two partial derivatives in order to use Eq. 8.37.

$$\frac{\partial f(x,y)}{\partial x} = 4x + 3$$
$$\frac{\partial f(x,y)}{\partial y} = -2y - 1$$
$$\nabla f(x,y) = (4x+3)\mathbf{i} + (-2y-1)\mathbf{j}$$

(b) The direction of the line passing through $(1,-2)$ with maximum slope is found by inserting $x = 1$ and $y = -2$ into the gradient vector function.

$$\mathbf{V} = [(4)(1)+3]\,\mathbf{i} + [(-2)(-2)-1]\,\mathbf{j}$$
$$= 7\mathbf{i} + 3\mathbf{j}$$

(c) The magnitude of the slope is

$$|\mathbf{V}| = \sqrt{(7)^2 + (3)^2} = \sqrt{58} = 7.62$$

9. DIRECTIONAL DERIVATIVE

Unlike the gradient vector (covered in Sec. 8), which calculates the maximum rate of change of a function, the *directional derivative*, indicated by $\nabla_u f(x,y,z)$, $D_u f(x,y,z)$, or $f'_u(x,y,z)$, gives the rate of change in the direction of a given vector, **u** or **U**. The subscript u implies that the direction vector is a unit vector, but it does not need to be, as only the direction cosines are calculated from it.

$$\nabla_u f(x,y,z) = \left(\frac{\partial f(x,y,z)}{\partial x}\right)\cos\alpha + \left(\frac{\partial f(x,y,z)}{\partial y}\right)\cos\beta + \left(\frac{\partial f(x,y,z)}{\partial z}\right)\cos\gamma \qquad 8.38$$

$$\mathbf{U} = U_x\mathbf{i} + U_y\mathbf{j} + U_z\mathbf{k} \qquad 8.39$$

$$\cos\alpha = \frac{U_x}{|\mathbf{U}|} = \frac{U_x}{\sqrt{U_x^2 + U_y^2 + U_z^2}} \qquad 8.40$$

$$\cos\beta = \frac{U_y}{|\mathbf{U}|} \qquad 8.41$$

$$\cos\gamma = \frac{U_z}{|\mathbf{U}|} \qquad 8.42$$

Example 8.11

What is the rate of change of $f(x,y) = 3x^2 + xy - 2y^2$ at the point $(1,-2)$ in the direction $4\mathbf{i} + 3\mathbf{j}$?

Solution

The direction cosines are given by Eqs. 8.40 and 8.41.

$$\cos\alpha = \frac{U_x}{|\mathbf{U}|} = \frac{4}{\sqrt{(4)^2 + (3)^2}} = \tfrac{4}{5}$$
$$\cos\beta = \frac{U_y}{|\mathbf{U}|} = \tfrac{3}{5}$$

The partial derivatives are

$$\frac{\partial f(x,y)}{\partial x} = 6x + y$$
$$\frac{\partial f(x,y)}{\partial y} = x - 4y$$

The directional derivative is given by Eq. 8.38.

$$\nabla_u f(x,y) = \left(\tfrac{4}{5}\right)(6x+y) + \left(\tfrac{3}{5}\right)(x-4y)$$

Substituting the given values of $x = 1$ and $y = -2$,

$$\nabla_u f(1,-2) = \left(\tfrac{4}{5}\right)[(6)(1)-2] + \left(\tfrac{3}{5}\right)[1-(4)(-2)]$$
$$= \tfrac{43}{5} = 8.6$$

10. NORMAL LINE VECTOR

Partial derivatives can be used to find the vector normal to a three-dimensional surface defined by $f(x,y,z) = 0$ at some point P_0. Notice that the coefficients of **i**, **j**, and **k** are the same as the coefficients of x, y, and z calculated for the equation of the tangent plane at point P_0. (See Secs. 7.13 and 8.7.)

$$\mathbf{N} = \left.\frac{\partial f(x,y,z)}{\partial x}\right|_{P_0}\mathbf{i} + \left.\frac{\partial f(x,y,z)}{\partial y}\right|_{P_0}\mathbf{j} + \left.\frac{\partial f(x,y,z)}{\partial z}\right|_{P_0}\mathbf{k} \qquad 8.43$$

Example 8.12

What is the vector normal to the surface of $f(x,y,z) = 4x^2 + y^2 - 16z = 0$ at the point $(2,4,2)$?

Solution

The equation of the tangent plane at this point was calculated in Ex. 8.9 to be

$$T(2,4,2) = 2x + y - 2z - 4 = 0$$

A vector normal to the tangent plane through this point is

$$\mathbf{N} = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$$

11. DIVERGENCE OF A VECTOR FIELD

The *divergence*, div **F**, of a vector field $\mathbf{F}(x, y, z)$ is a scalar function defined by Eqs. 8.44 through 8.46.[4] The divergence of **F** can be interpreted as the *accumulation* of flux (i.e., a flowing substance) in a small region (i.e., at a point). One of the uses of the divergence is to determine whether flow (represented in direction and magnitude by **F**) is compressible. Flow is incompressible if $\operatorname{div}\mathbf{F} = 0$, since the substance is not accumulating.

$$\mathbf{F} = P(x, y, z)\mathbf{i} + Q(x, y, z)\mathbf{j} + R(x, y, z)\mathbf{k} \quad 8.44$$

$$\operatorname{div}\mathbf{F} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z} \quad 8.45$$

It may be easier to calculate the divergence from Eq. 8.46.

$$\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F} \quad 8.46$$

The vector del operator, ∇, is defined as

$$\nabla = \frac{\partial}{\partial x}\mathbf{i} + \frac{\partial}{\partial y}\mathbf{j} + \frac{\partial}{\partial z}\mathbf{k} \quad 8.47$$

If there is no divergence, then the dot product calculated in Eq. 8.46 is zero.

Example 8.13

Calculate the divergence of the following vector function.

$$\mathbf{F}(x, y, z) = xz\mathbf{i} + e^x y\mathbf{j} + 7x^3 y\mathbf{k}$$

Solution

From Eq. 8.45,

$$\begin{aligned}\operatorname{div}\mathbf{F} &= \frac{\partial}{\partial x}(xz) + \frac{\partial}{\partial y}(e^x y) + \frac{\partial}{\partial z}(7x^3 y) \\ &= z + e^x + 0 = z + e^x\end{aligned}$$

12. CURL OF A VECTOR FIELD

The *curl*, curl **F**, of a vector field $\mathbf{F}(x, y, z)$ is a vector field defined by Eqs. 8.51 and 8.52. The curl **F** can be interpreted as the *vorticity* per unit area of flux (i.e., a flowing substance) in a small region (i.e., at a point). One of the uses of the curl is to determine whether flow (represented in direction and magnitude by **F**) is rotational. Flow is irrotational if curl $\mathbf{F} = 0$.[5]

$$\mathbf{F} = P(x, y, z)\mathbf{i} + Q(x, y, z)\mathbf{j} + R(x, y, z)\mathbf{k} \quad 8.48$$

[4]Notice that a bold letter, **F**, is used to indicate that the vector is a function of x, y, and z.

[5]If the velocity vector is **V**, then the *vorticity* is

$$\boldsymbol{\omega} = \nabla \times \mathbf{V} = \omega_x\mathbf{i} + \omega_y\mathbf{j} + \omega_z\mathbf{k} \quad 8.49$$

The *circulation* (defined in Chap. 17) is the line integral of the velocity **V** along a closed curve.

$$\Gamma = \oint \mathbf{V} \cdot d\mathbf{s} = \oint \boldsymbol{\omega} \cdot d\mathbf{A} \quad 8.50$$

$$\operatorname{curl}\mathbf{F} = \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}\right)\mathbf{j} + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)\mathbf{k} \quad 8.51$$

It may be easier to calculate the curl from Eq. 8.52. (The vector del operator, ∇, was defined in Eq. 8.47.)

$$\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ P(x, y, z) & Q(x, y, z) & R(x, y, z) \end{vmatrix} \quad 8.52$$

Example 8.14

Calculate the curl of the following vector function.

$$\mathbf{F}(x, y, z) = 3x^2\mathbf{i} + 7e^x y\mathbf{j}$$

Solution

Using Eq. 8.52,

$$\operatorname{curl}\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ 3x^2 & 7e^x y & 0 \end{vmatrix}$$

Expand the determinant across the top row.

$$\begin{aligned}&\mathbf{i}\left[\frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}(7e^x y)\right] - \mathbf{j}\left[\frac{\partial}{\partial x}(0) - \frac{\partial}{\partial z}(3x^2)\right] \\ &\quad + \mathbf{k}\left[\frac{\partial}{\partial x}(7e^x y) - \frac{\partial}{\partial y}(3x^2)\right] \\ &= \mathbf{i}(0 - 0) - \mathbf{j}(0 - 0) + \mathbf{k}(7e^x y - 0) = 7e^x y\mathbf{k}\end{aligned}$$

13. TAYLOR'S FORMULA

Taylor's formula (series) can be used to expand a function around a point (i.e., approximate the function at one point based on the function's value at another point). The approximation consists of a series, each term composed of a derivative of the original function and a polynomial. Using Taylor's formula requires that the original function be continuous in the interval $[a, b]$ and have the required number of derivatives. To expand a function, $f(x)$, around a point, a, in order to obtain $f(b)$, Taylor's formula is[6]

$$f(b) = f(a) + \frac{f'(a)}{1!}(b - a) + \frac{f''(a)}{2!}(b - a)^2 + \cdots + \frac{f^n(a)}{n!}(b - a)^n + R_n(b) \quad 8.53$$

[6]If $a = 0$, Eq. 8.53 is known as the *Maclaurin series*.

In Eq. 8.53, the expression f^n designates the nth derivative of the function $f(x)$. To be a useful approximation, point a must satisfy two requirements: It must be relatively close to point b, and the function and its derivatives must be known or easy to calculate. The last term, $R_n(b)$, is the uncalculated remainder after n derivatives. It is the difference between the exact and approximate values. By using enough terms, the remainder can be made arbitrarily small. That is, $R_n(b)$ approaches zero as n approaches infinity.

It can be shown that the remainder term can be calculated from Eq. 8.54, where c is some number in the interval $[a, b]$. With certain functions, the constant c can be completely determined. In most cases, however, it is possible only to calculate an upper bound on the remainder from Eq. 8.55. M_n is the maximum (positive) value of $f^{(n+1)}(x)$ on the interval $[a, b]$.

$$R_n(b) = \frac{f^{n+1}(c)}{(n+1)!}(b-a)^{n+1} \qquad 8.54$$

$$|R_n(b)| \leq M_n \frac{|(b-a)^{n+1}|}{(n+1)!} \qquad 8.55$$

14. COMMON SERIES APPROXIMATIONS

Taylor's formulas can be used (by expanding about $a = 0$) to derive the following series approximations.

$$\sin x \approx x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!} \qquad 8.56$$

$$\cos x \approx 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots + (-1)^n \frac{x^{2n}}{(2n)!} \qquad 8.57$$

$$\sinh x \approx x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots + \frac{x^{2n+1}}{(2n+1)!} \qquad 8.58$$

$$\cosh x \approx 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \cdots + \frac{x^{2n}}{(2n)!} \qquad 8.59$$

$$e^x \approx 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} \qquad 8.60$$

$$\ln(1+x) \approx x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots + (-1)^{n+1}\frac{x^n}{n} \qquad 8.61$$

$$\frac{1}{1-x} \approx 1 + x + x^2 + x^3 + \cdots + x^n \qquad 8.62$$

PRACTICE PROBLEMS

1. What are the values of a, b, and c in the following expression such that $n(\infty) = 100$, $n(0) = 10$, and $dn(0)/dt = 0.5$?

$$n(t) = \frac{a}{1 + be^{ct}}$$

(A) $a = 10,\ b = 9,\ c = 1$
(B) $a = 100,\ b = 10,\ c = 1.5$
(C) $a = 100,\ b = 9,\ c = -0.056$
(D) $a = 1000,\ b = 10,\ c = 0.056$

The answer is (C).

2. Find all minima, maxima, and inflection points for

$$y = x^3 - 9x^2 - 3$$

(A) maximum at $x = 0$
inflection at $x = 3$
minimum at $x = 6$

(B) maximum at $x = 0$
inflection at $x = -3$
minimum at $x = -6$

(C) minimum at $x = 0$
inflection at $x = 3$
maximum at $x = 6$

(D) minimum at $x = 3$
inflection at $x = 0$
maximum at $x = -3$

The answer is (A).

1. INTEGRATION

Integration is the inverse operation of differentiation. For that reason, *indefinite integrals* are sometimes referred to as *antiderivatives*.[1] Although expressions can be functions of several variables, integrals can only be taken with respect to one variable at a time. The *differential term* (dx in Eq. 9.1) indicates that variable. In Eq. 9.1, the function $f'(x)$ is the *integrand*, and x is the variable of integration.

$$\int f'(x)dx = f(x) + C \qquad 9.1$$

While most of a function, $f(x)$, can be "recovered" through integration of its derivative, $f'(x)$, a constant term will be lost. This is because the derivative of a constant term vanishes (i.e., is zero), leaving nothing to recover from. A *constant of integration*, C, is added to the integral to recognize the possibility of such a term.

2. ELEMENTARY OPERATIONS

Equations 9.2 through 9.8 summarize the elementary integration operations on polynomials and exponentials.[2]

[1]The difference between an indefinite and definite integral (covered in Sec. 7) is simple: An *indefinite integral* is a function, while a *definite integral* is a number.

[2]More extensive listings, known as *tables of integrals*, are widely available.

Equations 9.2 and 9.3 are particularly useful. (C and k represent constants. $f(x)$ and $g(x)$ are functions of x.)

$$\int k\,dx = kx + C \qquad 9.2$$

$$\int x^m\,dx = \frac{x^{m+1}}{m+1} + C \qquad [m \neq -1] \qquad 9.3$$

$$\int \frac{1}{x}dx = \ln|x| + C \qquad 9.4$$

$$\int e^{kx}dx = \frac{e^{kx}}{k} + C \qquad 9.5$$

$$\int xe^{kx}dx = \frac{e^{kx}(kx-1)}{k^2} + C \qquad 9.6$$

$$\int k^{ax}dx = \frac{k^{ax}}{a\ \ln\ k} + C \qquad 9.7$$

$$\int \ln\ x\,dx = x\ \ln\ x - x + C \qquad 9.8$$

Equations 9.9 through 9.20 summarize the elementary integration operations on transcendental functions.

$$\int \sin x\,dx = -\cos x + C \qquad 9.9$$

$$\int \cos x\,dx = \sin x + C \qquad 9.10$$

$$\int \tan x\,dx = \ln|\sec x| + C \qquad 9.11$$

$$\int \cot x\,dx = \ln|\sin x| + C \qquad 9.12$$

$$\int \sec x\,dx = \ln|(\sec x + \tan x)| + C \qquad 9.13$$

$$\int \csc x\,dx = \ln|(\csc x - \cot x)| + C \qquad 9.14$$

$$\int \frac{dx}{k^2 + x^2} = \frac{1}{k}\arctan\frac{x}{k} + C \qquad 9.15$$

$$\int \frac{dx}{\sqrt{k^2 - x^2}} = \arcsin\frac{x}{k} + C \qquad [k^2 > x^2] \qquad 9.16$$

$$\int \frac{dx}{x\sqrt{x^2 - k^2}} = \frac{1}{k}\operatorname{arcsec}\frac{x}{k} + C \qquad [x^2 > k^2] \qquad 9.17$$

$$\int \sin^2 x\,dx = \tfrac{1}{2}x - \tfrac{1}{4}\sin 2x + C \qquad 9.18$$

$$\int \cos^2 x\,dx = \tfrac{1}{2}x + \tfrac{1}{4}\sin 2x + C \qquad 9.19$$

$$\int \tan^2 x\,dx = \tan x - x + C \qquad 9.20$$

Equations 9.21 through 9.26 summarize the elementary integration operations on hyperbolic transcendental functions. Integrals of hyperbolic functions are not completely analogous to those of the regular transcendental functions.

$$\int \sinh x\,dx = \cosh x + C \qquad 9.21$$

$$\int \cosh x\,dx = \sinh x + C \qquad 9.22$$

$$\int \tanh x\,dx = \ln|\cosh x| + C \qquad 9.23$$

$$\int \coth x\,dx = \ln|\sinh x| + C \qquad 9.24$$

$$\int \operatorname{sech} x\,dx = \arctan(\sinh x) + C \qquad 9.25$$

$$\int \operatorname{csch} x\,dx = \ln\left|\tanh\left(\frac{x}{2}\right)\right| + C \qquad 9.26$$

Equations 9.27 through 9.31 summarize the elementary integration operations on functions and combinations of functions.

$$\int kf(x)dx = k\int f(x)dx \qquad 9.27$$

$$\int (f(x)+g(x))dx = \int f(x)dx + \int g(x)dx \qquad 9.28$$

$$\int \frac{f'(x)}{f(x)}dx = \ln|f(x)| + C \qquad 9.29$$

$$\begin{aligned}\int f(x)dg(x) &= f(x)\int dg(x) - \int g(x)df(x) + C \\ &= f(x)g(x) - \int g(x)df(x) + C\end{aligned} \qquad 9.30$$

Example 9.1

Find the integral with respect to x of

$$3x^2 + \tfrac{1}{3}x - 7 = 0$$

Solution

This is a polynomial function, and Eq. 9.3 can be applied to each of the three terms.

$$\int \left(3x^2 + \tfrac{1}{3}x - 7\right)dx = x^3 + \tfrac{1}{6}x^2 - 7x + C$$

3. INTEGRATION BY PARTS

Equation 9.30, repeated here, is known as *integration by parts*. $f(x)$ and $g(x)$ are functions. The use of this method is illustrated by Ex. 9.2.

$$\int f(x)dg(x) = f(x)g(x) - \int g(x)df(x) + C \qquad 9.31$$

Example 9.2

Find the following integral.

$$\int x^2e^x\,dx$$

Solution

x^2e^x is factored into two parts so that integration by parts can be used.

$$\begin{aligned}f(x) &= x^2 \\ dg(x) &= e^x\,dx \\ df(x) &= 2x\,dx \\ g(x) &= \int dg(x) = \int e^x\,dx = e^x\end{aligned}$$

From Eq. 9.31, disregarding the constant of integration (which cannot be evaluated),

$$\int f(x)dg(x) = f(x)g(x) - \int g(x)df(x)$$

$$\int x^2e^x\,dx = x^2e^x - \int e^x(2x)dx$$

The second term is also factored into two parts, and integration by parts is used again. This time,

$$\begin{aligned}f(x) &= x \\ dg(x) &= e^x\,dx \\ df(x) &= dx \\ g(x) &= \int dg(x) = \int e^x\,dx = e^x\end{aligned}$$

From Eq. 9.31,

$$\begin{aligned}\int 2xe^x\,dx &= 2\int xe^x\,dx \\ &= (2)\left(xe^x - \int e^x\,dx\right) \\ &= (2)(xe^x - e^x)\end{aligned}$$

Then, the complete integral is

$$\begin{aligned}\int x^2e^x\,dx &= x^2e^x - (2)(xe^x - e^x) + C \\ &= e^x(x^2 - 2x + 2) + C\end{aligned}$$

4. SEPARATION OF TERMS

Equation 9.28 shows that the integral of a sum of terms is equal to a sum of integrals. This technique is known as *separation of terms*. In many cases, terms are easily separated. In other cases, the technique of *partial fractions* (see Sec. 3.16) can be used to obtain individual terms. These techniques are illustrated by Exs. 9.3 and 9.4.

Example 9.3

Find the following integral.

$$\int \frac{(2x^2+3)^2}{x}dx$$

Solution

$$\begin{aligned}\int \frac{(2x^2+3)^2}{x}dx &= \int \frac{4x^4+12x^2+9}{x}dx \\ &= \int \left(4x^3+12x+\frac{9}{x}\right)dx \\ &= x^4+6x^2+9\ \ln|x|+C\end{aligned}$$

Example 9.4

Find the following integral.

$$\int \frac{3x+2}{3x-2}dx$$

Solution

The integrand is larger than 1, so use long division to simplify it.

$$\begin{array}{r} 1 \text{ rem } \frac{4}{3x-2} \\ 3x-2\ \overline{)\ 3x+2} \\ \underline{3x-2} \\ 4 \text{ remainder} \end{array}$$

$$\begin{aligned}\int \frac{3x+2}{3x-2}dx &= \int \left(1+\frac{4}{3x-2}\right)dx \\ &= \int dx + \int \frac{4}{3x-2}dx \\ &= x+\tfrac{4}{3}\ \ln|(3x-2)|+C\end{aligned}$$

5. DOUBLE AND HIGHER-ORDER INTEGRALS

A function can be successively integrated. (This is analogous to successive differentiation.) A function that is integrated twice is known as a *double integral*; if integrated three times, it is a *triple integral*; and so on. Double and triple integrals are used to calculate areas and volumes, respectively.

The successive integrations do not need to be with respect to the same variable. Variables not included in the integration are treated as constants.

There are several notations used for a multiple integral, particularly when the product of length differentials represents a differential area or volume. A double integral (i.e., two successive integrations) can be represented by one of the following notations.

$$\iint f(x,y)dx\,dy,\ \int_{R^2} f(x,y)dx\,dy,$$

$$\text{or } \iint_{R^2} f(x,y)dA$$

A triple integral can be represented by one of the following notations.

$$\iiint f(x,y,z)dx\,dy\,dz,$$

$$\int_{R^3} f(x,y,z)dx\,dy\,dz,$$

$$\text{or } \iiint_{R^3} f(x,y,z)dV$$

Example 9.5

Find the following double integral.

$$\iint (x^2+y^3x)dx\,dy$$

Solution

$$\int (x^2+y^3x)dx = \tfrac{1}{3}x^3+\tfrac{1}{2}y^3x^2+C_1$$

$$\int \left(\tfrac{1}{3}x^3+\tfrac{1}{2}y^3x^2+C_1\right)dy = \tfrac{1}{3}yx^3+\tfrac{1}{8}y^4x^2+C_1y+C_2$$

So,

$$\iint (x^2+y^3x)dx\,dy = \tfrac{1}{3}yx^3+\tfrac{1}{8}y^4x^2+C_1y+C_2$$

6. INITIAL VALUES

The constant of integration, C, can be found only if the value of the function $f(x)$ is known for some value of x_0. The value $f(x_0)$ is known as an *initial value*. To completely define a function, as many initial values, $f(x_0), f'(x_0), f''(x_0)$, and so on, as there are integrations are needed.

Example 9.6

It is known that $f(x) = 4$ when $x = 2$ (i.e., the initial condition is $f(2) = 4$). Find the original function.

$$\int (3x^3-7x)dx$$

Solution

The function is

$$f(x) = \int (3x^3 - 7x)dx = \tfrac{3}{4}x^4 - \tfrac{7}{2}x^2 + C$$

Substituting the initial value determines that C equals 6.

$$4 = \left(\tfrac{3}{4}\right)(2)^4 - \left(\tfrac{7}{2}\right)(2)^2 + C$$
$$4 = 12 - 14 + C$$
$$C = 6$$

The function is

$$f(x) = \tfrac{3}{4}x^4 - \tfrac{7}{2}x^2 + 6$$

7. DEFINITE INTEGRALS

A *definite integral* is restricted to a specific range of the independent variable. (Unrestricted integrals of the types shown in all preceding examples are known as *indefinite integrals*.) A definite integral restricted to the region bounded by *lower* and *upper limits* (also known as *bounds*), x_1 and x_2, is written as

$$\int_{x_1}^{x_2} f(x)dx$$

Equation 9.32 indicates how definite integrals are evaluated. It is known as the *fundamental theorem of calculus*.

$$\int_{x_1}^{x_2} f'(x)dx = f(x)\Big|_{x_1}^{x_2} = f(x_2) - f(x_1) \qquad 9.32$$

A common use of a definite integral is the calculation of work performed by a force, F, that moves from position x_1 to x_2.

$$W = \int_{x_1}^{x_2} F\,dx \qquad 9.33$$

Example 9.7

Evaluate the following definite integral.

$$\int_{\frac{\pi}{4}}^{\frac{\pi}{3}} \sin x\,dx$$

Solution

From Eq. 9.32,

$$\int_{\frac{\pi}{4}}^{\frac{\pi}{3}} \sin x\,dx = \Big[-\cos x\Big]_{\frac{\pi}{4}}^{\frac{\pi}{3}}$$
$$= -\cos\tfrac{\pi}{3} - \left(-\cos\tfrac{\pi}{4}\right)$$
$$= -0.5 - (-0.707) = 0.207$$

8. AVERAGE VALUE

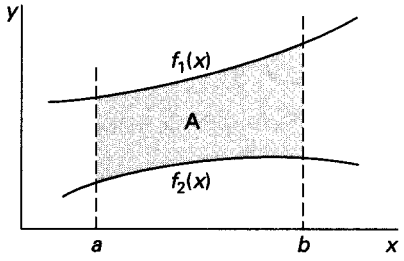
The average value of a function $f(x)$ that is integrable over the interval $[a, b]$ is

$$\text{average value} = \frac{1}{b-a}\int_a^b f(x)dx \qquad 9.34$$

9. AREA

Equation 9.35 calculates the area, A, bounded by $x = a$, $x = b$, $f_1(x)$ above and $f_2(x)$ below. ($f_2(x) = 0$ if the area is bounded by the x-axis.) This is illustrated in Fig. 9.1.

$$A = \int_a^b (f_1(x) - f_2(x))dx \qquad 9.35$$



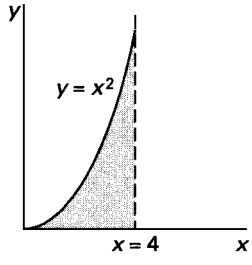


Figure 9.1 *Area Between Two Curves*

Example 9.8

Find the area between the x-axis and the parabola $y = x^2$ in the interval [0,4].

Solution

Referring to Eq. 9.35,

$$f_1(x) = x^2$$
$$f_2(x) = 0$$
$$A = \int_a^b (f_1(x) - f_2(x))dx = \int_0^4 x^2 dx$$
$$= \left[\frac{x^3}{3}\right]_0^4 = 64/3$$

10. ARC LENGTH

Equation 9.36 gives the length of a curve defined by $f(x)$ whose derivative exists in the interval $[a, b]$.

$$\text{length} = \int_a^b \sqrt{1 + (f'(x))^2}\, dx \qquad 9.36$$

11. PAPPUS' THEOREMS[3]

The first and second theorems of Pappus are:[4]

- *First Theorem*: Given a curve, C, that does not intersect the y-axis, the area of the *surface of revolution* generated by revolving C around the y-axis is equal to the product of the length of the curve and the circumference of the circle traced by the centroid of curve C.

$$A = \text{length} \times \text{circumference} = \text{length} \times 2\pi \times \text{radius} \qquad 9.37$$

- *Second Theorem*: Given a plane region, R, that does not intersect the y-axis, the *volume of revolution* generated by revolving R around the y-axis is equal to the product of the area and the circumference of the circle traced by the centroid of area R.

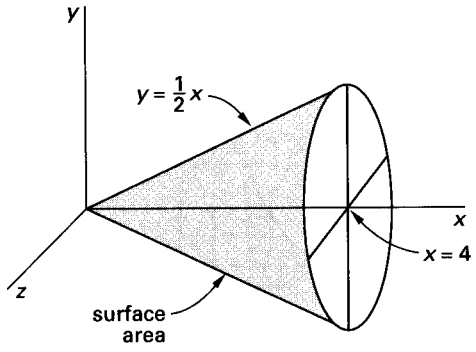
$$V = \text{area} \times \text{circumference} = \text{area} \times 2\pi \times \text{radius} \qquad 9.38$$

12. SURFACE OF REVOLUTION

The surface area obtained by rotating $f(x)$ about the x-axis is

$$A = 2\pi \int_{x=a}^{x=b} f(x)\sqrt{1 + (f'(x))^2}\, dx \qquad 9.39$$

The surface area obtained by rotating $f(y)$ about the y-axis is



$$A = 2\pi \int_{y=c}^{y=d} f(y)\sqrt{1 + (f'(y))^2}\, dy \qquad 9.40$$

Example 9.9

The curve $f(x) = {}^1\!/_2 x$ over the region $x = [0, 4]$ is rotated about the x-axis. What is the surface of revolution?

Solution

The surface of revolution is

Since $f(x) = {}^1\!/_2 x$, $f'(x) = {}^1\!/_2$. From Eq. 9.39, the area is

$$\begin{aligned}
A &= 2\pi \int_{x=a}^{x=b} f(x)\sqrt{1 + (f'(x))^2}\, dx \\
&= 2\pi \int_0^4 \tfrac{1}{2} x \sqrt{1 + \left(\tfrac{1}{2}\right)^2}\, dx \\
&= \frac{\sqrt{5}}{2}\pi \int_0^4 x\, dx \\
&= \frac{\sqrt{5}}{2}\pi \left[\frac{x^2}{2}\right]_0^4 \\
&= \frac{\sqrt{5}}{2}\pi \left(\frac{(4)^2 - (0)^2}{2}\right) \\
&= 4\sqrt{5}\pi
\end{aligned}$$

13. VOLUME OF REVOLUTION

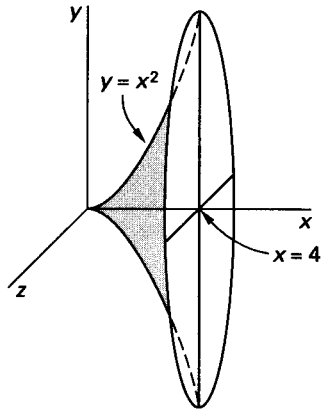
The volume obtained by rotating $f(x)$ about the x-axis is given by Eq. 9.41. $f^2(x)$ is the square of the function, not the second derivative.

$$V = \pi \int_{x=a}^{x=b} f^2(x)\, dx \qquad 9.41$$

The volume obtained by rotating $f(x)$ about the y-axis is

$$V = 2\pi \int_{x=a}^{x=b} x f(x)\, dx \qquad 9.42$$

[3]This section is an introduction to surfaces and volumes of revolution but does not involve integration.



[4]Some authorities call the first theorem the second and vice versa.

Example 9.10

The curve $f(x) = x^2$ over the region $x = [0, 4]$ is rotated about the x-axis. What is the volume of revolution?

Solution

The volume of revolution is

$$V = \pi \int_a^b f^2(x)dx = \pi \int_0^4 (x^2)^2 dx$$
$$= \pi \left[\frac{x^5}{5}\right]_0^4 = \pi \left(\frac{1024}{5} - 0\right) = 204.8\pi$$

14. MOMENTS OF A FUNCTION

The *first moment of a function* is a concept used in finding centroids and centers of gravity. Equations 9.43 and 9.44 are for one- and two-dimensional problems, respectively. It is the exponent of x (1 in this case) that gives the moment its name.

$$\text{first moment} = \int xf(x)dx \qquad 9.43$$

$$\text{first moment} = \iint xf(x,y)dx\,dy \qquad 9.44$$

The *second moment of a function* is a concept used in finding moments of inertia with respect to an axis. Equations 9.45 and 9.46 are for two- and three-dimensional problems, respectively. Second moments with respect to other axes are analogous.

$$(\text{second moment})_x = \iint y^2 f(x,y)dy\,dx \qquad 9.45$$

$$(\text{second moment})_x = \iiint (y^2 + z^2) f(x,y,z)dy\,dz\,dx \qquad 9.46$$

15. FOURIER SERIES

Any periodic waveform can be written as the sum of an infinite number of sinusoidal terms, known as *harmonic terms* (i.e., an infinite series). Such a sum of terms is known as a *Fourier series*, and the process of finding the terms is *Fourier analysis*. (Extracting the original waveform from the series is known as *Fourier inversion*.) Since most series converge rapidly, it is possible to obtain a good approximation to the original waveform with a limited number of sinusoidal terms.

Fourier's theorem is Eq. 9.47.[5] The object of a Fourier analysis is to determine the coefficients a_n and b_n. The constant a_0 can often be determined by inspection since it is the average value of the waveform.

$$f(t) = a_0 + a_1 \cos\omega t + a_2 \cos 2\omega t + \cdots + b_1 \sin\omega t + b_2 \sin 2\omega t + \cdots \qquad 9.47$$

ω is the *natural (fundamental) frequency* of the waveform. It depends on the actual waveform period, T.

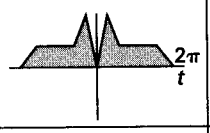
$$\omega = \frac{2\pi}{T} \qquad 9.48$$

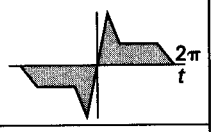
To simplify the analysis, the time domain can be normalized to the radian scale. The normalized scale is obtained by dividing all frequencies by ω. Then the Fourier series becomes

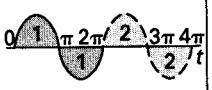
$$f(t) = a_0 + a_1 \cos t + a_2 \cos 2t + \cdots + b_1 \sin t + b_2 \sin 2t + \cdots \qquad 9.49$$

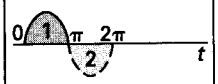
The coefficients a_n and b_n are found from the following relationships.

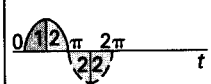
$$a_0 = \frac{1}{2\pi}\int_0^{2\pi} f(t)dt = \frac{1}{T}\int_0^T f(t)dt \qquad 9.50$$











$$a_n = \frac{1}{\pi}\int_0^{2\pi} f(t)\cos nt\,dt = \frac{2}{T}\int_0^T f(t)\cos nt\,dt \qquad [n \geq 1] \qquad 9.51$$

$$b_n = \frac{1}{\pi}\int_0^{2\pi} f(t)\sin nt\,dt = \frac{2}{T}\int_0^T f(t)\sin nt\,dt \qquad [n \geq 1] \qquad 9.52$$

While Eqs. 9.51 and 9.52 are always valid, the work of integrating and finding a_n and b_n can be greatly simplified if the waveform is recognized as being symmetrical. Table 9.1 summarizes the simplifications.

[5]The independent variable used in this section is t, since Fourier analysis is most frequently used in the time domain.

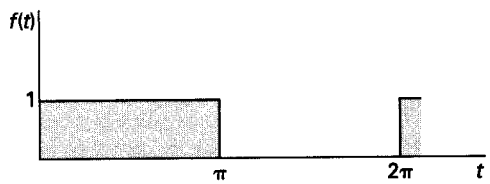


Table 9.1 *Fourier Analysis Simplifications for Symmetrical Waveforms*

	even symmetry $f(-t) = f(t)$ 	odd symmetry $f(-t) = -f(t)$ 
full-wave symmetry* $f(t + 2\pi) = f(t)$  $\lvert A_2\rvert = \lvert A_1\rvert$ $\lvert A_{total}\rvert = \lvert A_1\rvert$ *any repeating wave form	$b_n = 0$ [all n] $a_n = \frac{1}{\pi}\int_0^{2\pi} f(t)\cos nt\,dt$ [all n]	$a_0 = 0$ $a_n = 0$ [all n] $b_n = \frac{1}{\pi}\int_0^{2\pi} f(t)\sin nt\,dt$ [all n]
half-wave symmetry* $f(t + \pi) = -f(t)$  $\lvert A_2\rvert = \lvert A_1\rvert$ $\lvert A_{total}\rvert = 2\lvert A_1\rvert$ *same as rotational symmetry	$a_n = 0$ [even n] $b_n = 0$ [all n] $a_n = \frac{2}{\pi}\int_0^{\pi} f(t)\cos nt\,dt$ [odd n]	$a_0 = 0$ $a_n = 0$ [all n] $b_n = 0$ [even n] $b_n = \frac{2}{\pi}\int_0^{\pi} f(t)\sin nt\,dt$ [odd n]
quarter-wave symmetry $f(t + \pi) = -f(t)$  $\lvert A_2\rvert = \lvert A_1\rvert$ $\lvert A_{total}\rvert = 4\lvert A_1\rvert$	$a_0 = 0$ $a_n = 0$ [even n] $b_n = 0$ [all n] $a_n = \frac{4}{\pi}\int_0^{\frac{\pi}{2}} f(t)\cos nt\,dt$ [odd n]	$a_0 = 0$ $a_n = 0$ [all n] $b_n = 0$ [even n] $b_n = \frac{4}{\pi}\int_0^{\frac{\pi}{2}} f(t)\sin nt\,dt$ [odd n]

Example 9.11

Find the first four terms of a Fourier series that approximates the repetitive step function illustrated.

$$f(t) = \begin{Bmatrix} 1 & 0 < t < \pi \\ 0 & \pi < t < 2\pi \end{Bmatrix}$$

Solution

From Eq. 9.50,

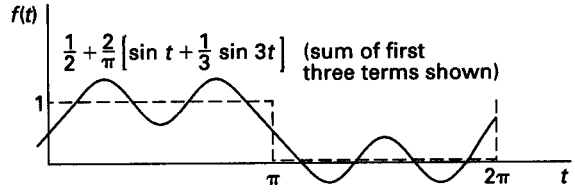
$$a_0 = \frac{1}{2\pi}\int_0^{\pi}(1)\,dt + \frac{1}{2\pi}\int_{\pi}^{2\pi}(0)\,dt = \tfrac{1}{2}$$

This value of 1/2 corresponds to the average value of $f(t)$. It could have been found by observation.

$$a_1 = \frac{1}{\pi}\int_0^{\pi}(1)\cos t\,dt + \frac{1}{\pi}\int_{\pi}^{2\pi}(0)\cos t\,dt$$
$$= \frac{1}{\pi}\left[\sin t\right]_0^{\pi} + 0 = 0$$

In general,

$$a_n = \frac{1}{\pi}\left[\frac{\sin nt}{n}\right]_0^{\pi} = 0$$



$$b_1 = \frac{1}{\pi}\int_0^{\pi}(1)\sin t\,dt + \frac{1}{\pi}\int_{\pi}^{2\pi}(0)\sin t\,dt$$
$$= \frac{1}{\pi}\left[-\cos t\right]_0^{\pi} = \frac{2}{\pi}$$

In general,

$$b_n = \frac{1}{\pi}\left[\frac{-\cos nt}{n}\right]_0^{\pi} = \begin{cases} 0 & \text{for } n \text{ even} \\ \dfrac{2}{\pi n} & \text{for } n \text{ odd} \end{cases}$$

The series is

$$f(t) = \tfrac{1}{2} + \tfrac{2}{\pi}\left[\sin t + \tfrac{1}{3}\sin 3t + \tfrac{1}{5}\sin 5t + \cdots\right]$$

16. FAST FOURIER TRANSFORMS

Many mathematical operations are needed to implement a true Fourier transform. While the terms of a Fourier series might be slowly derived by integration, a faster method is needed to analyze real-time data. The *fast Fourier transform* (FFT) is a computer algorithm implemented in *spectrum analyzers (signal analyzers* or *FFT analyzers*) and replaces integration and multiplication operations with table look-ups and additions.[6]

[6] *Spectrum analysis*, also known as *frequency analysis, signature analysis*, and *time-series analysis*, develops a relationship (usually graphical) between some property (e.g., amplitude or phase shift) versus frequency.

Since the complexity of the transform is reduced, the transformation occurs more quickly, enabling efficient analysis of waveforms with little or no periodicity.[7]

Using a spectrum analyzer requires choosing the frequency band (e.g., 0 to 20 kHz) to be monitored. (This step automatically selects the sampling period. The lower the frequencies sampled, the longer the sampling period.) If they are not fixed by the analyzer, the numbers of time-dependent input variable samples (e.g., 1024) and frequency-dependent output variable values (e.g., 400) are chosen.[8] There are half as many frequency lines as data points because each line contains two pieces of information—real (amplitude) and imaginary (phase). The *resolution* of the resulting frequency analysis is

$$\text{resolution} = \frac{\text{frequency bandwidth}}{\text{no. of output variable values}} \qquad 9.53$$

17. INTEGRAL FUNCTIONS

Integrals that cannot be evaluated as finite combinations of elementary functions are called *integral functions*. These functions are evaluated by series expansion. Some of the more common functions are listed as follows.[9,10]

- *integral sine function*:

$$\begin{aligned}\text{Si}(x) &= \int_0^x \frac{\sin x}{x}\,dx \\ &= x - \frac{x^3}{3 \cdot 3!} + \frac{x^5}{5 \cdot 5!} - \frac{x^7}{7 \cdot 7!} + \cdots\end{aligned} \qquad 9.54$$

- *integral cosine function*:

$$\begin{aligned}\text{Ci}(x) &= \int_{-\infty}^{x} \frac{\cos x}{x}\,dx = -\int_{x}^{\infty} \frac{\cos x}{x}\,dx \\ &= C_E + \ln\, x - \frac{x^2}{2 \cdot 2!} + \frac{x^4}{4 \cdot 4!} - \cdots\end{aligned} \qquad 9.55$$

- *integral exponential function*:

$$\begin{aligned}\text{Ei}(x) &= \int_{-\infty}^{x} \frac{e^x}{x}\,dx = -\int_{-x}^{\infty} \frac{e^{-x}}{x}\,dx \\ &= C_E + \ln\, x + x + \frac{x^2}{2 \cdot 2!} + \frac{x^3}{3 \cdot 3!} + \cdots\end{aligned} \qquad 9.56$$

- *error function*:

$$\begin{aligned}\text{erf}(x) &= \frac{2}{\sqrt{\pi}} \int_0^x e^{-x^2}\,dx \\ &= \left(\frac{2}{\sqrt{\pi}}\right)\left(\frac{x}{1 \cdot 0!} - \frac{x^3}{3 \cdot 1!} + \frac{x^5}{5 \cdot 2!} - \frac{x^7}{7 \cdot 3!} + \cdots\right)\end{aligned} \qquad 9.57$$

[7]Hours and days of manual computations are compressed into milliseconds.

[8]Two samples per time-dependent cycle (at the maximum frequency) is the lower theoretical limit for sampling, but the practical minimum rate is approximately 2.5 samples per cycle. This will ensure that *alias components* (i.e., low-level frequency signals) do not show up in the frequency band of interest.

[9]Other integral functions include the Fresnel integral, gamma function, and elliptic integral.

[10]C_E in Eqs. 9.55 and 9.56 is *Euler's constant*.

$$\begin{aligned}C_E &= \int_{+\infty}^{0} e^{-x}\, ln\, x\, dx \\ &= \lim_{m \to \infty} \left(1 + \tfrac{1}{2} + \tfrac{1}{3} + \cdots + \frac{1}{m} - ln\, m\right) \\ &= 0.577215665\end{aligned}$$

Practice Problems 10-10

1. TYPES OF DIFFERENTIAL EQUATIONS

A *differential equation* is a mathematical expression combining a function (e.g., $y = f(x)$) and one or more of its derivatives. The *order* of a differential equation is the highest derivative in it. *First-order differential equations* contain only first derivatives of the function, *second-order differential equations* contain second derivatives (and may contain first derivatives as well), and so on.

A *linear differential equation* can be written as a sum of products of multipliers of the function and its derivatives. If the multipliers are scalars, the differential equation is said to have *constant coefficients*. If the function or one of its derivatives is raised to some power (other than one) or is embedded in another function (e.g., y embedded in $\sin y$ or e^y), the equation is said to be *nonlinear*.

Each term of a *homogeneous differential equation* contains either the function (y) or one of its derivatives—that is, the sum of derivative terms is equal to zero. In a *nonhomogeneous differential equation*, the sum of derivative terms is equal to a nonzero *forcing function* of the independent variable (e.g., $g(x)$). In order to solve a nonhomogeneous equation, it is often necessary to solve the homogeneous equation first. The homogeneous equation corresponding to a nonhomogeneous equation is known as a *reduced equation* or *complementary equation*.

The following examples illustrate the types of differential equations.

• $y' - 7y = 0$	homogeneous, first-order linear, with constant coefficients
• $y'' - 2y' + 8y = \sin 2x$	nonhomogeneous, second-order linear, with constant coefficients
• $y'' - (x^2 - 1)y^2 = \sin 4x$	nonhomogeneous, second-order, nonlinear

An *auxiliary equation* (also called the *characteristic equation*) can be written for a homogeneous linear differential equation with constant coefficients, regardless of order. This auxiliary equation is simply the polynomial formed by replacing all derivatives with variables raised to the power of their respective derivatives.

The purpose of solving a differential equation is to derive an expression for the function in terms of the independent variable. The expression does not need to be explicit in the function, but there can be no derivatives in the expression. Since, in the simplest cases, solving a differential equation is equivalent to finding an indefinite integral, it is not surprising that *constants of integration* must be evaluated from knowledge of how the system behaves. Additional data are known as *initial*

values, and any problem that includes them is known as an *initial value problem.*[1]

Most differential equations require lengthy solutions and are not efficiently solved by hand. However, several types are fairly simple and are presented in this chapter.

Example 10.1

Write the complementary differential equation for the following nonhomogeneous differential equation.

$$y'' + 6y' + 9y = e^{-14x} \sin 5x$$

Solution

The complementary equation is found by eliminating the forcing function, $e^{-14x} \sin 5x$.

$$y'' + 6y' + 9y = 0$$

Example 10.2

Write the auxiliary equation to the following differential equation.

$$y'' + 4y' + y = 0$$

Solution

Replacing each derivative with a polynomial term whose degree equals the original order, the auxiliary equation is

$$r^2 + 4r + 1 = 0$$

2. HOMOGENEOUS, FIRST-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

A homogeneous, first-order linear differential equation with constant coefficients has the general form of Eq. 10.1.

$$y' + ky = 0 \qquad 10.1$$

The auxiliary equation is $r + k = 0$ and has a root of $r = -k$. Equation 10.2 is the solution.

$$y = Ae^{rx} = Ae^{-kx} \qquad 10.2$$

[1]The term *initial* implies that time is the independent variable. While this may explain the origin of the term, initial value problems are not limited to the time domain. A *boundary value problem* is similar, except that the data come from different points. For example, additional data in the form $y(x_0)$ and $y'(x_0)$ or $y(x_0)$ and $y'(x_1)$ that need to be simultaneously satisfied constitute an initial value problem. Data of the form $y(x_0)$ and $y(x_1)$ constitute a boundary value problem. Until solved, it is difficult to know whether a boundary value problem has no, one, or more than one solution.

If the initial condition is known to be $y(0) = y_0$, the solution is

$$y = y_0 e^{-kx} \qquad 10.3$$

3. FIRST-ORDER LINEAR DIFFERENTIAL EQUATIONS

A first-order linear differential equation has the general form of Eq. 10.4. $p(x)$ and $g(x)$ can be constants or any function of x (but not of y). However, if $p(x)$ is a constant and $g(x)$ is zero, it is easier to solve the equation as shown in Sec. 2.

$$y' + p(x)y = g(x) \qquad 10.4$$

The *integrating factor* (which is actually a function) to this differential equation is

$$u(x) = \exp\left[\int p(x)dx\right] \qquad 10.5$$

The closed-form solution to Eq. 10.4 is

$$y = \frac{1}{u(x)}\left[\int u(x)g(x)dx + C\right] \qquad 10.6$$

For the special case where $p(x)$ and $g(x)$ are both constants, Eq. 10.4 becomes

$$y' + ay = b \qquad 10.7$$

If the initial condition is $y(0) = y_0$, the solution to Eq. 10.7 is

$$y = \left(\frac{b}{a}\right)(1 - e^{-ax}) + y_0 e^{-ax} \qquad 10.8$$

Example 10.3

Find a solution to the following differential equation.

$$y' - y = 2xe^{2x} \qquad y(0) = 1$$

Solution

This is a first-order linear equation with $p(x) = -1$ and $g(x) = 2xe^{2x}$. The integrating factor is

$$u(x) = \exp\left[\int p(x)dx\right] = \exp\left[\int -1dx\right] = e^{-x}$$

The solution is given by Eq. 10.6.

$$\begin{aligned} y &= \frac{1}{u(x)}\left[\int u(x)g(x)dx + C\right] \\ &= \frac{1}{e^{-x}}\left[\int e^{-x}2xe^{2x}dx + C\right] \\ &= e^{x}\left[2\int xe^{x}dx + C\right] \\ &= e^{x}[2xe^{x} - 2e^{x} + C] \\ &= e^{x}[2e^{x}(x-1) + C] \end{aligned}$$

From the initial condition,

$$\begin{aligned} y(0) &= 1 \\ e^{0}[(2)(e^{0})(0-1) + C] &= 1 \\ 1[(2)(1)(-1) + C] &= 1 \end{aligned}$$

Therefore, $C = 3$. The complete solution is

$$y = e^{x}[2e^{x}(x-1) + 3]$$

4. FIRST-ORDER SEPARABLE DIFFERENTIAL EQUATIONS

First-order separable differential equations can be placed in the form of Eq. 10.9. For clarity, y' is written as dy/dx.

$$m(x) + n(y)\frac{dy}{dx} = 0 \qquad 10.9$$

Equation 10.9 can be placed in the form of Eq. 10.10, both sides of which are easily integrated. An initial value will establish the constant of integration.

$$m(x)dx = -n(y)dy \qquad 10.10$$

5. FIRST-ORDER EXACT DIFFERENTIAL EQUATIONS

A *first-order exact differential equation* has the form

$$f_x(x,y) + f_y(x,y)y' = 0 \qquad 10.11$$

Notice that $f_x(x,y)$ is the exact derivative of $f(x,y)$ with respect to x, and $f_y(x,y)$ is the exact derivative of $f(x,y)$ with respect to y. The solution is

$$f(x,y) - C = 0 \qquad 10.12$$

6. HOMOGENEOUS, SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

Homogeneous second-order linear differential equations with constant coefficients have the form of Eq. 10.13. They are most easily solved by finding the two roots of the auxiliary equation (Eq. 10.14).

$$y'' + k_1y' + k_2y = 0 \qquad 10.13$$

$$r^2 + k_1r + k_2 = 0 \qquad 10.14$$

There are three cases. If the two roots of Eq. 10.14 are real and different, the solution is

$$y = A_1e^{r_1x} + A_2e^{r_2x} \qquad 10.15$$

If the two roots are real and the same, the solution is

$$y = A_1e^{rx} + A_2xe^{rx} \qquad 10.16$$

$$r = \frac{-k_1}{2} \qquad 10.17$$

If the two roots are imaginary, they will be of the form $(\alpha + i\omega)$ and $(\alpha - i\omega)$, and the solution is

$$y = A_1e^{\alpha x}\cos\omega x + A_2e^{\alpha x}\sin\omega x \qquad 10.18$$

In all three cases, A_1 and A_2 must be found from the two initial conditions.

Example 10.4

Solve the following differential equation.

$$y'' + 6y' + 9y = 0$$

$$y(0) = 0 \qquad y'(0) = 1$$

Solution

The auxiliary equation is

$$\begin{aligned} r^2 + 6r + 9 &= 0 \\ (r+3)(r+3) &= 0 \end{aligned}$$

The roots to the auxiliary equation are $r_1 = r_2 = -3$. Therefore, the solution has the form of Eq. 10.16.

$$y = A_1e^{-3x} + A_2xe^{-3x}$$

The first initial condition is

$$\begin{aligned} y(0) &= 0 \\ A_1e^{0} + A_2(0)e^{0} &= 0 \\ A_1 + 0 &= 0 \\ A_1 &= 0 \end{aligned}$$

To use the second initial condition, the derivative of the equation is needed. Making use of the known fact that $A_1 = 0$,

$$y' = \frac{d}{dx}\left(A_2xe^{-3x}\right) = -3A_2xe^{-3x} + A_2e^{-3x}$$

Using the second initial condition,

$$y'(0) = 1$$
$$-3A_2(0)e^0 + A_2e^0 = 1$$
$$0 + A_2 = 1$$
$$A_2 = 1$$

The solution is

$$y = xe^{-3x}$$

7. NONHOMOGENEOUS DIFFERENTIAL EQUATIONS

A nonhomogeneous equation has the form of Eq. 10.19. $f(x)$ is known as the *forcing function*.

$$y'' + p(x)y' + q(x)y = f(x) \qquad 10.19$$

The solution to Eq. 10.19 is the sum of two equations. The *complementary solution*, y_c, solves the complementary (i.e., homogeneous) problem. The *particular solution*, y_p, is any specific solution to the nonhomogeneous Eq. 10.19 that is known or can be found. Initial values are used to evaluate any unknown coefficients in the complementary solution *after* y_c and y_p have been combined. (The particular solution will not have any unknown coefficients.)

$$y = y_c + y_p \qquad 10.20$$

Two methods are available for finding a particular solution. The *method of undetermined coefficients*, as presented here, can be used only when $p(x)$ and $q(x)$ are constant coefficients and $f(x)$ takes on one of the forms in Table 10.1.

The particular solution can be read from Table 10.1 if the forcing function is of one of the forms given. Of course, the coefficients A_i and B_i are not known—these are the *undetermined coefficients*. The exponent s is the smallest nonnegative number (and will be 0, 1, or 2), which ensures that no term in the particular solution, y_p, is also a solution to the complementary equation, y_c. s must be determined prior to proceeding with the solution procedure.

Table 10.1 *Particular Solutions**

form of $f(x)$	form of y_p
$P_n(x) = a_0x^n + a_1x^{n-1} + \cdots + a_n$	$x^s(A_0x^n + A_1x^{n-1} + \cdots + A_n)$
$P_n(x)e^{\alpha x}$	$x^s(A_0x^n + A_1x^{n-1} + \cdots + A_n)e^{\alpha x}$
$P_n(x)e^{\alpha x}\left\{\begin{matrix}\sin \omega x \\ \cos \omega x\end{matrix}\right\}$	$x^s[(A_0x^n + A_1x^{n-1} + \cdots + A_n)e^{\alpha x}\cos \omega x + (B_0x^n + B_1x^{n-1} + \cdots + B_n)e^{\alpha x}\sin \omega x]$

*$P_n(x)$ is a polynomial of degree n.

Once y_p (including s) is known, it is differentiated to obtain y_p' and y_p'', and all three functions are substituted into the original nonhomogeneous equation. The resulting equation is rearranged to match the forcing function, $f(x)$, and the unknown coefficients are determined, usually by solving simultaneous equations.

If the forcing function, $f(x)$, is more complex than the forms shown in Table 10.1, or if either $p(x)$ or $q(x)$ is a function of x, the method of *variation of parameters* should be used. This complex and time-consuming method is not covered in this book.

Example 10.5

Solve the following nonhomogeneous differential equation.

$$y'' + 2y' + y = e^x \cos x$$

Solution

step 1: Find the solution to the complementary (homogeneous) differential equation.

$$y'' + 2y' + y = 0$$

Since this is a differential equation with constant coefficients, write the auxiliary equation.

$$r^2 + 2r + 1 = 0$$

The auxiliary equation factors in $(r+1)^2 = 0$ with two identical roots at $r = -1$. Therefore, the solution to the homogeneous differential equation is

$$y_c(x) = C_1e^{-x} + C_2xe^{-x}$$

step 2: Use Table 10.1 to determine the form of a particular solution. Since the forcing function has the form $P_n(x)e^{\alpha x}\cos \omega x$ with $P_n(x) = 1$ (equivalent to $n = 0$), $\alpha = 1$, and $\omega = 1$, the particular solution has the form

$$y_p(x) = x^s(Ae^x \cos x + Be^x \sin x)$$

step 3: Determine the value of s. Check to see if any of the terms in $y_p(x)$ will themselves solve the homogeneous equation. Try $Ae^x \cos x$ first.

$$\frac{d}{dx}(Ae^x \cos x) = Ae^x \cos x - Ae^x \sin x$$

$$\frac{d^2}{dx^2}(Ae^x \cos x) = -2Ae^x \sin x$$

Substitute these quantities into the homogeneous equation.

$$y'' + 2y' + y = 0$$
$$-2Ae^x \sin x + 2Ae^x \cos x$$
$$-2Ae^x \sin x + Ae^x \cos x = 0$$
$$3Ae^x \cos x - 4Ae^x \sin x = 0$$

Disregarding the trivial ($A = 0$) solution, $Ae^x \cos x$ does not solve the homogeneous equation.

Next, try $Be^x \sin x$.

$$\frac{d}{dx}(Be^x \sin x) = Be^x \cos x + Be^x \sin x$$

$$\frac{d^2}{dx^2}(Be^x \sin x) = 2Be^x \cos x$$

Substitute these quantities into the homogeneous equation.

$$y'' + 2y' + y = 0$$
$$2Be^x \cos x + 2Be^x \cos x$$
$$+ 2Be^x \sin x + Be^x \sin x = 0$$
$$3Be^x \sin x + 4Be^x \cos x = 0$$

Disregarding the trivial ($B = 0$) case, $Be^x \sin x$ does not solve the homogeneous equation.

Since none of the terms in $y_p(x)$ solve the homogeneous equation, $s = 0$, and a particular solution has the form

$$y_p(x) = Ae^x \cos x + Be^x \sin x$$

step 4: Use the method of unknown coefficients to determine A and B in the particular solution. Drawing on the previous steps, substitute the quantities derived from the particular solution into the nonhomogeneous equation.

$$y'' + 2y' + y = e^x \cos x$$
$$-2Ae^x \sin x + 2Be^x \cos x$$
$$+ 2Ae^x \cos x - 2Ae^x \sin x$$
$$+ 2Be^x \cos x + 2Be^x \sin x$$
$$+ Ae^x \cos x + Be^x \sin x = e^x \cos x$$

Combining terms,

$$(-4A + 3B)e^x \sin x + (3A + 4B)e^x \cos x = e^x \cos x$$

Equating the coefficients of like terms on either side of the equal sign results in the following simultaneous equations.

$$-4A + 3B = 0$$
$$3A + 4B = 1$$

The solution to these equations is

$$A = \tfrac{3}{25}$$
$$B = \tfrac{4}{25}$$

A particular solution is

$$y_p(x) = \left(\tfrac{3}{25}\right)(e^x \cos x) + \left(\tfrac{4}{25}\right)(e^x \sin x)$$

step 5: Write the general solution.

$$y(x) = y_c(x) + y_p(x)$$
$$= C_1 e^{-x} + C_2 x e^{-x} + \left(\tfrac{3}{25}\right)(e^x \cos x)$$
$$+ \left(\tfrac{4}{25}\right)(e^x \sin x)$$

The values of C_1 and C_2 would be determined at this time if initial conditions were known.

8. NAMED DIFFERENTIAL EQUATIONS

Some differential equations with specific forms are named after the individuals who developed solution techniques for them.

- *Bessel equation of order ν:*

$$x^2y'' + xy' + (x^2 - \nu^2)y = 0 \qquad 10.21$$

- *Cauchy equation:*

$$a_0 x^n \frac{d^n y}{dx^n} + a_1 x^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \cdots + a_{n-1} x \frac{dy}{dx} + a_n y = f(x) \qquad 10.22$$

- *Euler equation:*

$$x^2y'' + \alpha xy' + \beta y = 0 \qquad 10.23$$

- *Gauss' hypergeometric equation:*

$$x(1-x)y'' + [c - (a+b+1)x]y' - aby = 0 \qquad 10.24$$

- *Legendre equation of order λ:*

$$(1 - x^2)y'' - 2xy' + \lambda(\lambda + 1)y = 0 \quad [-1 < x < 1] \qquad 10.25$$

9. LAPLACE TRANSFORMS

Traditional methods of solving nonhomogeneous differential equations by hand are usually difficult and/or time consuming. *Laplace transforms* can be used to reduce many solution procedures to simple algebra.

Every mathematical function, $f(t)$, for which Eq. 10.26 exists has a Laplace transform, written as $\mathcal{L}(f)$ or $F(s)$. The transform is written in the s-domain, regardless

of the independent variable in the original function.[2] (The variable s is equivalent to a derivative operator, although it may be handled in the equations as a simple variable.) Equation 10.26 converts a function into a Laplace transform.

$$\mathcal{L}(f(t)) = F(s) = \int_0^\infty e^{-st} f(t)dt \qquad 10.26$$

Equation 10.26 is not often needed because tables of transforms are readily available. (Appendix 10.A contains some of the most common transforms.)

Extracting a function from its transform is the *inverse Laplace transform* operation. Although other methods exist, this operation is almost always done by finding the transform in a set of tables.[3]

$$f(t) = \mathcal{L}^{-1}(F(s)) \qquad 10.27$$

Example 10.6

Find the Laplace transform of the following function.

$$f(t) = e^{at} \qquad [s > a]$$

Solution

Applying Eq. 10.26,

$$\mathcal{L}(e^{at}) = \int_0^\infty e^{-st}e^{at}dt = \int_0^\infty e^{-(s-a)t}dt$$
$$= -\left[\frac{e^{-(s-a)t}}{s-a}\right]_0^\infty = \frac{1}{s-a} \qquad [s > a]$$

10. STEP AND IMPULSE FUNCTIONS

Many forcing functions are sinusoidal or exponential in nature; others, however, can only be represented by a step or impulse function. A *unit step function*, u_t, is a function describing the disturbance of magnitude 1 that is not present before time t but is suddenly there after time t. A step of magnitude 5 at time $t = 3$ would be represented as $5u_3$. (The notation $5u(t-3)$ is used in some books.)

The *unit impulse function*, δ_t, is a function describing a disturbance of magnitude 1 that is applied and removed so quickly as to be instantaneous. An impulse of magnitude 5 at time 3 would be represented by $5\delta_3$. (The notation $5\delta(t-3)$ is used in some books.)

[2]It is traditional to write the original function as a function of the independent variable t rather than x. However, Laplace transforms are not limited to functions of time.

[3]Other methods include integration in the complex plane, convolution, and simplification by partial fractions.

Example 10.7

What is the notation for a forcing function of magnitude 6 that is applied at $t = 2$ and completely removed at $t = 7$?

Solution

The notation is $f(t) = 6(u_2 - u_7)$.

Example 10.8

Find the Laplace transform of u_0, a unit step at $t = 0$.

$$f(t) = 0 \text{ for } t < 0$$
$$f(t) = 1 \text{ for } t \geq 0$$

Solution

Since the Laplace transform is an integral that starts at $t = 0$, the value of $f(t)$ prior to $t = 0$ is irrelevant.

$$\mathcal{L}(u_0) = \int_0^\infty e^{-st}(1)dt = -\left[\frac{e^{-st}}{s}\right]_0^\infty$$
$$= 0 - \left(\frac{-1}{s}\right) = \frac{1}{s}$$

11. ALGEBRA OF LAPLACE TRANSFORMS

Equations containing Laplace transforms can be simplified by applying the following principles.

- *linearity theorem*: (c is a constant.)

$$\mathcal{L}(cf(t)) = c\mathcal{L}(f(t)) = cF(s) \qquad 10.28$$

- *superposition theorem*: ($f(t)$ and $g(t)$ are different functions.)

$$\mathcal{L}(f(t)) \pm g(t)) = \mathcal{L}(f(t)) \pm \mathcal{L}(g(t))$$
$$= F(s) \pm G(s) \qquad 10.29$$

- *time-shifting theorem (delay theorem)*:

$$\mathcal{L}(f(t-b)u_b) = e^{-bs}F(s) \qquad 10.30$$

- *Laplace transform of a derivative*:

$$\mathcal{L}(f^n(t)) = -f^{n-1}(0) - sf^{n-2}(0) - \cdots$$
$$- s^{n-1}f(0) + s^nF(s) \qquad 10.31$$

- *other properties*:

$$\mathcal{L}\left(\int_0^t f(u)du\right) = \left(\frac{1}{s}\right)F(s) \qquad 10.32$$

$$\mathcal{L}(tf(t)) = -\frac{dF}{ds} \qquad 10.33$$

$$\mathcal{L}\left(\frac{1}{t}f(t)\right) = \int_s^\infty F(u)du \qquad 10.34$$

12. CONVOLUTION INTEGRAL

A complex Laplace transform, $F(s)$, will often be recognized as the product of two other transforms, $F_1(s)$ and $F_2(s)$, whose corresponding functions $f_1(t)$ and $f_2(t)$ are known. Unfortunately, Laplace transforms cannot be computed with ordinary multiplication. That is, $f(t) \neq f_1(t)f_2(t)$ even though $F(s) = F_1(s)F_2(s)$.

However, it is possible to extract $f(t)$ from its *convolution*, $h(t)$, as calculated from either of the *convolution integrals* in Eq. 10.35. This process is demonstrated in Ex. 10.9. χ is a dummy variable.

$$\begin{aligned} f(t) &= \mathcal{L}^{-1}(F_1(s)F_2(s)) \\ &= \int_0^t f_1(t-\chi)f_2(\chi)d\chi \\ &= \int_0^t f_1(\chi)f_2(t-\chi)d\chi \end{aligned} \qquad 10.35$$

Example 10.9

Use the convolution integral to find the inverse transform of

$$F(s) = \frac{3}{s^2(s^2+9)}$$

Solution

$F(s)$ can be factored as

$$F_1(s)F_2(s) = \left(\frac{1}{s^2}\right)\left(\frac{3}{s^2+9}\right)$$

Since the inverse transforms of $F_1(s)$ and $F_2(s)$ are $f_1(t) = t$ and $f_2(t) = \sin 3t$, respectively, the convolution integral from Eq. 10.35 is

$$\begin{aligned} f(t) &= \int_0^t (t-\chi)\sin 3\chi \, d\chi \\ &= \int_0^t (t \sin 3\chi - \chi \sin 3\chi)d\chi \\ &= t\int_0^t \sin 3\chi \, d\chi - \int_0^t \chi \sin 3\chi \, d\chi \end{aligned}$$

Expand using integration by parts.

$$f(t) = \frac{3t - \sin 3t}{9}$$

13. USING LAPLACE TRANSFORMS

Any nonhomogeneous linear differential equation with constant coefficients can be solved with the following procedure, which reduces the solution to simple algebra. A complete table of transforms simplifies or eliminates step 5.

step 1: Put the differential equation in standard form (i.e., isolate the y'' term).

$$y'' + k_1y' + k_2y = f(t) \qquad 10.36$$

step 2: Take the Laplace transform of both sides. Use the linearity and superposition theorems, Eqs. 10.28 and 10.29.

$$\mathcal{L}(y'') + k_1\mathcal{L}(y') + k_2\mathcal{L}(y) = \mathcal{L}(f(t)) \qquad 10.37$$

step 3: Use Eqs. 10.38 and 10.39 to expand the equation. (These are specific forms of Eq. 10.31.) Use a table to evaluate the transform of the forcing function.

$$\mathcal{L}(y'') = s^2\mathcal{L}(y) - sy(0) - y'(0) \qquad 10.38$$

$$\mathcal{L}(y') = s\mathcal{L}(y) - y(0) \qquad 10.39$$

step 4: Use algebra to solve for $\mathcal{L}(y)$.

step 5: If needed, use partial fractions (see Ch. 3) to simplify the expression for $\mathcal{L}(y)$.

step 6: Take the inverse transform to find $y(t)$.

$$y(t) = \mathcal{L}^{-1}(\mathcal{L}(y)) \qquad 10.40$$

Example 10.10

Find $y(t)$ for the following differential equation.

$$y'' + 2y' + 2y = \cos t$$
$$y(0) = 1 \qquad y'(0) = 0$$

Solution

step 1: The equation is already in standard form.

step 2: $\mathcal{L}(y'') + 2\mathcal{L}(y') + 2\mathcal{L}(y) = \mathcal{L}(\cos t)$

step 3: Use Eqs. 10.38 and 10.39. Use App. 10.A to find the transform of $\cos t$.

$$s^2\mathcal{L}(y) - sy(0) - y'(0) + 2s\mathcal{L}(y) - 2y(0) + 2\mathcal{L}(y) = \frac{s}{s^2+1}$$

But, $y(0) = 1$ and $y'(0) = 0$.

$$s^2\mathcal{L}(y) - s + 2s\mathcal{L}(y) - 2 + 2\mathcal{L}(y) = \frac{s}{s^2+1}$$

step 4: Combine terms and solve for $\mathcal{L}(y)$.

$$\begin{aligned} \mathcal{L}(y)(s^2+2s+2) - s - 2 &= \frac{s}{s^2+1} \\ \mathcal{L}(y) &= \frac{\frac{s}{s^2+1} + s + 2}{s^2+2s+2} \\ &= \frac{s^3+2s^2+2s+2}{(s^2+1)(s^2+2s+2)} \end{aligned}$$

step 5: Expand the expression for $\mathcal{L}(y)$ by partial fractions. (Refer to Ch. 3.)

$$\mathcal{L}(y) = \frac{s^3 + 2s^2 + 2s + 2}{(s^2+1)(s^2+2s+2)} = \frac{A_1 s + B_1}{s^2+1} + \frac{A_2 s + B_2}{s^2+2s+2}$$

$$= \frac{[s^3(A_1 + A_2) + s^2(2A_1 + B_1 + B_2) + s(2A_1 + 2B_1 + A_2) + (2B_1 + B_2)]}{(s^2+1)(s^2+2s+2)}$$

The following simultaneous equations result.

$$\begin{aligned} A_1 + A_2 &= 1 \\ 2A_1 + B_1 + B_2 &= 2 \\ 2A_1 + A_2 + 2B_1 &= 2 \\ 2B_1 + B_2 &= 2 \end{aligned}$$

These equations have the solutions $A_1 = {}^1/_5$, $A_2 = {}^4/_5$, $B_1 = {}^2/_5$, and $B_2 = {}^6/_5$.

step 6: Refer to App. 10.A and take the inverse transforms.

$$\begin{aligned} y &= \mathcal{L}^{-1}(\mathcal{L}(y)) \\ &= \mathcal{L}^{-1}\left(\frac{\left(\frac{1}{5}\right)(s+2)}{s^2+1} + \frac{\left(\frac{1}{5}\right)(4s+6)}{s^2+2s+2}\right) \\ &= \left(\tfrac{1}{5}\right)\left(\mathcal{L}^{-1}\left(\frac{s}{s^2+1}\right) + 2\mathcal{L}^{-1}\left(\frac{1}{s^2+1}\right)\right. \\ &\quad + 4\mathcal{L}^{-1}\left(\frac{s-(-1)}{[s-(-1)]^2+1}\right) \\ &\quad \left. + 2\mathcal{L}^{-1}\left(\frac{1}{[s-(-1)]^2+1}\right)\right) \\ &= \tfrac{1}{5}(\cos t + 2\sin t + 4e^{-t}\cos t + 2e^{-t}\sin t) \end{aligned}$$

14. THIRD- AND HIGHER-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

The solutions of third- and higher-order linear differential equations with constant coefficients are extensions of the solutions for second-order equations of this type. Specifically, if an equation is homogeneous, the auxiliary equation is written and its roots are found. If the equation is nonhomogeneous, Laplace transforms can be used to simplify the solution.

Consider the following homogeneous differential equation with constant coefficients.

$$y^n + k_1 y^{n-1} + \cdots + k_{n-1} y' + k_n y = 0 \qquad 10.41$$

The auxiliary equation to Eq. 10.41 is

$$r^n + k_1 r^{n-1} + \cdots + k_{n-1} r + k_n = 0 \qquad 10.42$$

For each real and distinct root r, the solution contains the term

$$y = Ae^{rx} \qquad 10.43$$

For each real root r that repeats m times, the solution contains the term

$$y = \left(A_1 + A_2 x + A_3 x^2 + \cdots + A_m x^{m-1}\right) e^{rx} \qquad 10.44$$

For each pair of complex roots of the form $r = \alpha \pm i\omega$, the solution contains the terms

$$y = e^{\alpha x}(A_1 \sin \omega x + A_2 \cos \omega x) \qquad 10.45$$

15. APPLICATION: ENGINEERING SYSTEMS

There is a wide variety of engineering systems (mechanical, electrical, fluid flow, heat transfer, and so on) whose behavior is described by linear differential equations with constant coefficients.

16. APPLICATION: MIXING

A typical mixing problem involves a liquid-filled tank. The liquid may initially be pure or contain some solute. Liquid (either pure or as a solution) enters the tank at a known rate. A drain may be present to remove thoroughly mixed liquid. The concentration of the solution (or, equivalently, the amount of solute in the tank) at some given time is generally unknown.

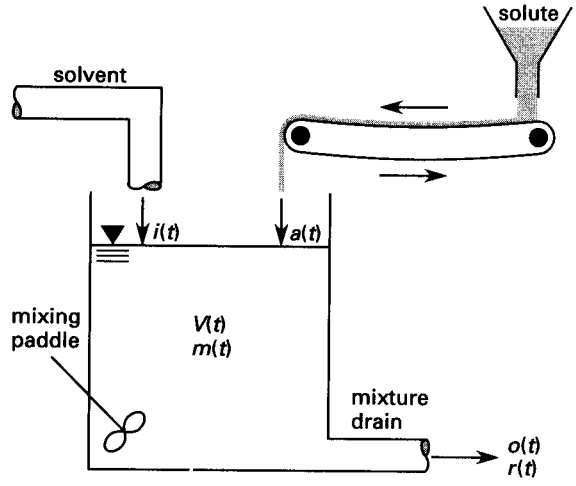

Figure 10.1 *Fluid Mixture Problem*

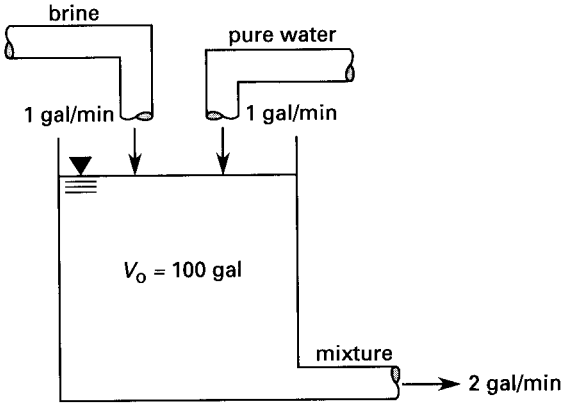
If $m(t)$ is the mass of solute in the tank at time t, the rate of solute change will be $m'(t)$. If the solute is being added at the rate of $a(t)$ and being removed at the rate of $r(t)$, the rate of change is

$$\begin{aligned} m'(t) &= \text{rate of addition} - \text{rate of removal} \\ &= a(t) - r(t) \end{aligned} \qquad 10.46$$

The rate of solute addition $a(t)$ must be known and, in fact, may be constant. However, $r(t)$ depends on the concentration, $c(t)$, of the mixture and volumetric flow rates at time t. If $o(t)$ is the volumetric flow rate out of the tank, then

$$r(t) = c(t)o(t) \qquad 10.47$$

However, the concentration depends on the mass of solute in the tank at time t. Recognizing that the volume, $V(t)$, of the liquid in the tank may be changing with time,



$$c(t) = \frac{m(t)}{V(t)} \qquad 10.48$$

The differential equation describing this problem is

$$m'(t) = a(t) - \frac{m(t)o(t)}{V(t)} \qquad 10.49$$

Example 10.11

A tank contains 100 gal of pure water at the beginning of an experiment. Pure water flows into the tank at a rate of 1 gal/min. Brine containing $^1/_4$ lbm of salt per gallon enters the tank from a second source at a rate of 1 gal/min. A perfectly mixed solution drains from the tank at a rate of 2 gal/min. How much salt is in the tank 8 min after the experiment begins?

Solution

Let $m(t)$ be the mass of salt in the tank at time t. 0.25 lbm of salt enters the tank per minute (i.e., $a(t) = 0.25$ lbm/min). The salt removal rate depends on the concentration in the tank. That is,

$$\begin{aligned} r(t) &= o(t)c(t) \\ &= \left(2\ \frac{\text{gal}}{\text{min}}\right)\left(\frac{m(t)}{100\ \text{gal}}\right) = \left(0.02\ \frac{1}{\text{min}}\right)m(t) \end{aligned}$$

From Eq. 10.46, the rate of change of salt in the tank is

$$\begin{aligned} m'(t) &= a(t) - r(t) \\ &= 0.25\ \frac{\text{lbm}}{\text{min}} - \left(0.02\ \frac{1}{\text{min}}\right)m(t) \end{aligned}$$

$$m'(t) + \left(0.02\ \frac{1}{\text{min}}\right)m(t) = 0.25\ \text{lbm/min}$$

This is a first-order linear differential equation of the form of Eq. 10.7. Since the initial condition is $m(0) = 0$, the solution is

$$\begin{aligned} m(t) &= \left(\frac{0.25\ \frac{\text{lbm}}{\text{min}}}{0.02\ \frac{1}{\text{min}}}\right)\left(1 - e^{(0.02\ \frac{1}{\text{min}})t}\right) \\ &= (12.5\ \text{lbm})\left(1 - e^{(-0.02\ \frac{1}{\text{min}})t}\right) \end{aligned}$$

At $t = 8$,

$$\begin{aligned} m(t) &= \left(12.5\ \frac{1}{\text{min}}\right)\left(1 - e^{-(0.02\ \frac{1}{\text{min}})(8\ \text{min})}\right) \\ &= (12.5\ \text{lbm})(1 - 0.852) \\ &= 1.85\ \text{lbm} \end{aligned}$$

17. APPLICATION: EXPONENTIAL GROWTH AND DECAY

Equation 10.50 describes the behavior of a substance whose quantity, $m(t)$, changes at a rate proportional to the quantity present. The constant of proportionality, k, will be negative for decay (e.g., radioactive decay) and positive for growth (e.g., compound interest).

$$m'(t) = km(t) \qquad 10.50$$

$$m'(t) - km(t) = 0 \qquad 10.51$$

If the initial quantity of substance is $m(0) = m_0$, Eq. 10.51 has the solution

$$m(t) = m_0 e^{kt} \qquad 10.52$$

If $m(t)$ is known for some time t, the constant of proportionality is

$$k = \left(\frac{1}{t}\right)\ln\left(\frac{m(t)}{m_0}\right) \qquad 10.53$$

For the case of a decay, the *half-life*, $t_{1/2}$, is the time at which only half of the substance remains. The relationship between k and $t_{1/2}$ is

$$kt_{1/2} = \ln\left(\tfrac{1}{2}\right) = -0.693 \qquad 10.54$$

18. APPLICATION: EPIDEMICS

During an epidemic in a population of n people, the density of sick (contaminated, contagious, affected, etc.) individuals is $\rho_s(t) = s(t)/n$, where $s(t)$ is the number of sick individuals at time t. Similarly, the density of well (uncontaminated, unaffected, susceptible, etc.) individuals is $\rho_\omega(t) = \omega(t)/n$, where $\omega(t)$ is the number of well individuals. Assuming there is no quarantine, the population size is constant, individuals move about freely, and sickness does not limit the activities of individuals, the rate of contagion, $\rho_s'(t)$, will be $k\rho_s(t)\rho_\omega(t)$, where k is a proportionality constant.

$$\rho_s'(t) = k\rho_s(t)\rho_\omega(t) = k\rho_s(t)(1 - \rho_s(t)) \qquad 10.55$$

This is a separable differential equation with the solution

$$\rho_s(t) = \frac{\rho_s(0)}{\rho_s(0) + (1 - \rho_s(0))e^{-kt}} \qquad 10.56$$

19. APPLICATION: SURFACE TEMPERATURE

Newton's law of cooling states that the surface temperature, T, of a cooling object changes at a rate proportional to the difference between the surface and ambient temperatures. The constant k is a positive number.

$$T'(t) = -k(T(t) - T_{\text{ambient}}) \quad [\text{k>0}] \qquad 10.57$$

$$T'(t) + kT(t) - kT_{\text{ambient}} = 0 \quad [\text{k>0}] \qquad 10.58$$

This first-order linear differential equation with constant coefficients has the following solution (from Eq. 10.8).

$$T(t) = T_{\text{ambient}} + (T(0) - T_{\text{ambient}})e^{-kt} \qquad 10.59$$

If the temperature is known at some time t, the constant k can be found from Eq. 10.60.

$$k = \left(\frac{-1}{t}\right) \ln\left(\frac{T(t) - T_{\text{ambient}}}{T(0) - T_{\text{ambient}}}\right) \qquad 10.60$$

20. APPLICATION: EVAPORATION

The mass of liquid evaporated from a liquid surface is proportional to the exposed surface area. Since quantity, mass, and remaining volume are all proportional, the differential equation is

$$\frac{dV}{dt} = -kA \qquad 10.61$$

For a spherical drop of radius r, Eq. 10.61 reduces to

$$\frac{dr}{dt} = -k \qquad 10.62$$

$$r(t) = r(0) - kt \qquad 10.63$$

For a cube with sides of length s, Eq. 10.61 reduces to

$$\frac{ds}{dt} = -2k \qquad 10.64$$

$$s(t) = s(0) - 2kt \qquad 10.65$$

PRACTICE PROBLEMS

1. Solve the following differential equation for y.

$$y'' - 4y' - 12y = 0$$

(A) $A_1e^{6x} + A_2e^{-2x}$
(B) $A_1e^{-6x} + A_2e^{2x}$
(C) $A_1e^{6x} + A_2e^{2x}$
(D) $A_1e^{-6x} + A_2e^{-2x}$

The answer is (A).

2. Solve the following differential equation for y.

$$y' - y = 2xe^{2x} \qquad y(0) = 1$$

(A) $y = 2e^{-2x}(x - 1) + 3e^{-x}$
(B) $y = 2e^{2x}(x - 1) + 3e^{x}$
(C) $y = -2e^{-2x}(x - 1) + 3e^{-x}$
(D) $y = 2e^{2x}(x - 1) + 3e^{-x}$

The answer is (B).

3. The oscillation exhibited by the top story of a certain building in free motion is given by the following differential equation.

$$x'' + 2x' + 2x = 0 \qquad x(0) = 0 \qquad x'(0) = 1$$

(a) What is x as a function of time?
(A) $e^{-2t}\sin t$
(B) $e^{t}\sin t$
(C) $e^{-t}\sin t$
(D) $e^{-t}\sin t + e^{-t}\cos t$

The answer is (C).

(b) What is the building's fundamental natural frequency of vibration?
(A) $1/2$
(B) 1
(C) $\sqrt{2}$
(D) 2

The answer is (C).

(c) What is the amplitude of oscillation?
(A) 0.32
(B) 0.54
(C) 1.7
(D) 6.6

The answer is (A).

(d) What is x as a function of time if a lateral wind load is applied with a form of $\sin t$?

(A) $\frac{6}{5}e^{-t}\sin t + \frac{2}{5}e^{-t}\cos t$

(B) $\frac{6}{5}e^{t}\sin t + \frac{2}{5}e^{t}\cos t$

(C) $\frac{2}{5}e^{-t}\sin t + \frac{6}{5}e^{-t}\cos t + \frac{2}{5}\sin t - \frac{1}{5}\cos t$

(D) $\frac{6}{5}e^{-t}\sin t + \frac{2}{5}e^{-t}\cos t + \frac{1}{5}\sin t - \frac{2}{5}\cos t$

The answer is (D).

4. (*Time limit: one hour*) A 90 lbm (40 kg) bag of a chemical is accidentally dropped in an aerating lagoon. The chemical is water soluble and nonreacting. The lagoon is 120 ft (35 m) in diameter and filled to a depth of 10 ft (3 m). The aerators circulate and distribute the chemical evenly throughout the lagoon.

Water enters the lagoon at a rate of 30 gal/min (115 L/min). Fully mixed water is pumped into a reservoir at a rate of 30 gal/min (115 L/min). The established safe concentration of this chemical is 1 ppb (part per billion). How many days will it take for the concentration of the discharge water to reach this level?

(A) 25 days

(B) 50 days

(C) 100 days

(D) 200 days

The answer is (D).

5. A tank contains 100 gal (100 L) of brine made by dissolving 60 lbm (60 kg) of salt in pure water. Salt water with a concentration of 1 lbm/gal (1 kg/L) enters the tank at a rate of 2 gal/min (2 L/min). A well-stirred mixture is drawn from the tank at a rate of 3 gal/min (3 L/min). Find the mass of salt in the tank after 1 hr.

(A) 13 lbm (13 kg)

(B) 37 lbm (37 kg)

(C) 43 lbm (43 kg)

(D) 51 lbm (51 kg)

The answer is (B).

Practice Problems 11-15

1. SET THEORY

A *set* (usually designated by a capital letter) is a population or collection of individual items known as *elements* or *members*. The *null set*, ϕ, is empty (i.e., contains no members). If A and B are two sets, A is a *subset* of B if every member in A is also in B. A is a *proper subset* of B if B consists of more than the elements in A. These relationships are denoted

$A \subseteq B$ [subset]

$A \subset B$ [proper subset]

The *universal set*, U, is one from which other sets draw their members. If A is a subset of U, then A' (also designated as A^{-1}, $\tilde{A}$, $-A$, and $\bar{A}$) is the *complement* of A and consists of all elements in U that are not in A. This is illustrated in a *Venn diagram* in Fig. 11.1(a).

The *union of two sets*, denoted by $A \cup B$ and shown in Fig. 11.1(b), is the set of all elements that are either in A or B or both. The *intersection of two sets*, denoted by $A \cap B$ and shown in Fig. 11.1(c), is the set of all elements that belong to both A and B. If $A \cap B = \phi$, A and B are said to be *disjoint sets*.

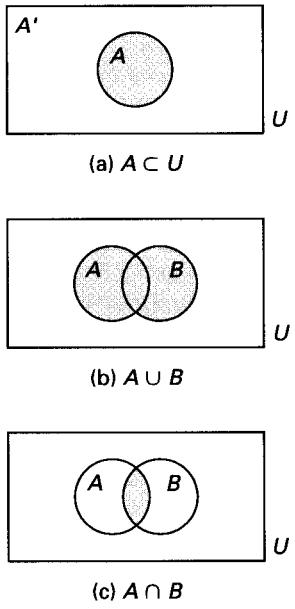

Figure 11.1 *Venn Diagrams*

If A, B, and C are subsets of the universal set, the following laws apply.

- *identity laws*:

$$A \cup \phi = A \quad (11.1)$$
$$A \cup U = U \quad (11.2)$$
$$A \cap \phi = \phi \quad (11.3)$$
$$A \cap U = A \quad (11.4)$$

- *idempotent laws*:

$$A \cup A = A \quad (11.5)$$
$$A \cap A = A \quad (11.6)$$

- *complement laws*:

$$A \cup A' = U \quad (11.7)$$
$$(A')' = A \quad (11.8)$$
$$A \cap A' = \phi \quad (11.9)$$
$$U' = \phi \quad (11.10)$$

- *commutative laws*:

$$A \cup B = B \cup A \qquad 11.11$$
$$A \cap B = B \cap A \qquad 11.12$$

- *associative laws*:

$$(A \cup B) \cup C = A \cup (B \cup C) \qquad 11.13$$
$$(A \cap B) \cap C = A \cap (B \cap C) \qquad 11.14$$

- *distributive laws*:

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C) \qquad 11.15$$
$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C) \qquad 11.16$$

- *de Morgan's laws*:

$$(A \cup B)' = A' \cap B' \qquad 11.17$$
$$(A \cap B)' = A' \cup B' \qquad 11.18$$

2. COMBINATIONS OF ELEMENTS

There are a finite number of ways in which n elements can be combined into distinctly different groups of r items. For example, suppose a farmer has a hen, a rooster, a duck, and a cage that holds only two birds. The possible *combinations* of three birds taken two at a time are (hen, rooster), (hen, duck), and (rooster, duck). The birds in the cage will not remain stationary, and the combination (rooster, hen) is not distinctly different from (hen, rooster). That is, the groups are not *order conscious*.

The number of combinations of n items taken r at a time is written $C(n,r)$, C_r^n, ${}_nC_r$, or $\binom{n}{r}$ (pronounced "n choose r") and given by Eq. 11.19. It is sometimes referred to as the *binomial coefficient*.

$$\binom{n}{r} = C(n,r) = \frac{n!}{(n-r)!r!} \qquad [\text{for } r \leq n] \qquad 11.19$$

Example 11.1

Six people are on a sinking yacht. There are four life jackets. How many combinations of survivors are there?

Solution

The groups are not order conscious. From Eq. 11.19,

$$C(6,4) = \frac{6!}{(6-4)!4!} = \frac{6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1}{(2 \cdot 1)(4 \cdot 3 \cdot 2 \cdot 1)} = 15$$

3. PERMUTATIONS

An order-conscious subset of r items taken from a set of n items is the *permutation* $P(n,r)$, also written P_r^n and ${}_nP_r$. The permutation is order conscious because the arrangement of two items (say a_i and b_i) as a_ib_i is different from the arrangement b_ia_i. The number of permutations is

$$P(n,r) = \frac{n!}{(n-r)!} \qquad [\text{for } r \leq n] \qquad 11.20$$

If groups of the entire set of n items are being enumerated, the number of permutations of n items taken n at a time is

$$P(n,n) = \frac{n!}{(n-n)!} = \frac{n!}{0!} = n! \qquad 11.21$$

A *ring permutation* is a special case of n items taken n at a time. There is no identifiable beginning or end, and the number of permutations is divided by n.

$$P_{\text{ring}}(n,n) = \frac{P(n,n)}{n} = (n-1)! \qquad 11.22$$

Example 11.2

A pianist knows four pieces but will have enough stage time to play only three of them. Pieces played in a different order constitute a different program. How many different programs can be arranged?

Solution

The groups are order conscious. From Eq. 11.20,

$$P(4,3) = \frac{4!}{(4-3)!} = \frac{4 \cdot 3 \cdot 2 \cdot 1}{1} = 24$$

Example 11.3

Seven diplomats from different countries enter a circular room. The only furnishings are seven chairs arranged around a circular table. How many ways are there of arranging the diplomats?

Solution

All seven diplomats must be seated, so the groups are permutations of seven objects taken seven at a time. Since there is no head chair, the groups are ring permutations. From Eq. 11.22,

$$P_{\text{ring}}(7,7) = (7-1)! = 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 = 720$$

4. PROBABILITY THEORY

The act of conducting an experiment (trial) or taking a measurement is known as *sampling*. *Probability theory* determines the relative likelihood that a particular event will occur. An *event*, e, is one of the possible outcomes of the *trial*. Taken together, all of the

possible events constitute a finite *sample space*, $E = [e_1, e_2, \ldots, e_n]$. The trial is drawn from the *population* or *universe*. Populations can be finite or infinite in size.

Events can be numerical or nonnumerical, discrete or continuous, and dependent or independent. An example of a nonnumerical event is getting tails on a coin toss. The roll of a die is a discrete numerical event. The measured diameter of a bolt produced from an automatic screw machine is a numerical event. Since the diameter can (within reasonable limits) take on any value, its measured value is a continuous numerical event.

An event is *independent* if its outcome is unaffected by previous outcomes (i.e., previous runs of the experiment) and *dependent* otherwise. Whether or not an event is independent depends on the population size and how the sampling is conducted. Sampling (a trial) from an infinite population is implicitly independent. When the population is finite, *sampling with replacement* produces independent events, while *sampling without replacement* changes the population and produces dependent events.

The terms *success* and *failure* are loosely used in probability theory to designate obtaining and not obtaining, respectively, the tested-for condition. "Failure" is not the same as a *null event* (i.e., one that has a zero probability of occurrence).

The *probability* of event e_1 occurring is designated as $p\{e_1\}$ and is calculated as the ratio of the total number of ways the event can occur to the total number of outcomes in the sample space.

Example 11.4

There are 380 students in a rural school—200 girls and 180 boys. One student is chosen at random and is checked for gender and height. (a) Define and categorize the population. (b) Define and categorize the sample space. (c) Define the trials. (d) Define and categorize the events. (e) In determining the probability that the student chosen is a boy, define success and failure. (f) What is the probability that the student is a boy?

Solution

(a) The population consists of 380 students and is finite.

(b) In determining the gender of the student, the sample space consists of the two outcomes $E = [\text{girl, boy}]$. This sample space is nonnumerical and discrete. In determining the height, the sample space consists of a range of values and is numerical and continuous.

(c) The trial is the actual sampling (i.e., the determination of gender and height).

(d) The events are the outcomes of the trials (i.e., the gender and height of the student). These events are independent if each student returns to the population prior to the random selection of the next student; otherwise, the events are dependent.

(e) The event is a success if the student is a boy and is a failure otherwise.

(f) From the definition of probability,

$$p\{\text{boy}\} = \frac{\text{no. of boys}}{\text{no. of students}} = \frac{180}{380} = \frac{9}{19} = 0.47$$

5. JOINT PROBABILITY

Joint probability rules specify the probability of a combination of events. If n mutually exclusive events from the set E have probabilities $p\{e_i\}$, the probability of any one of these events occurring in a given trial is the sum of the individual probabilities. Notice that the events in Eq. 11.23 come from a single sample space and are linked by the word *or*.

$$p\{e_1 \text{ or } e_2 \text{ or } \ldots \text{or } e_k\} = p\{e_1\} + p\{e_2\} + \ldots + p\{e_k\} \qquad 11.23$$

Given two independent sets of events, E and G, Eq. 11.24 gives the probability that either event e_i or g_i, or both, will occur. Notice that the events in Eq. 11.24 come from two different sample spaces and are linked by the word *or*.

$$p\{e_i \text{ or } g_i\} = p\{e_i\} + p\{g_i\} - p\{e_i\}p\{g_i\} \qquad 11.24$$

Given two independent sets of events, E and G, Eq. 11.25 gives the probability that events e_i and g_i will both occur. Notice that the events in Eq. 11.25 come from two different sample spaces and are linked by the word *and*.

$$p\{e_i \text{ and } g_i\} = p\{e_i\}p\{g_i\} \qquad 11.25$$

Example 11.5

A bowl contains five white balls, two red balls, and three green balls. What is the probability of getting either a white ball or a red ball in one draw from the bowl?

Solution

The two possible events are mutually exclusive and come from the same sample space, so Eq. 11.23 can be used.

$$p\{\text{white or red}\} = p\{\text{white}\} + p\{\text{red}\} = \frac{5}{10} + \frac{2}{10} = \frac{7}{10}$$

Example 11.6

One bowl contains five white balls, two red balls, and three green balls. Another bowl contains three yellow balls and seven black balls. What is the probability of getting a red ball from the first bowl and a yellow ball from the second bowl in one draw from each bowl?

Solution

The two trials are independent, so Eq. 11.25 can be used.

$$\begin{aligned} p\{\text{red and yellow}\} &= p\{\text{red}\}p\{\text{yellow}\} \\ &= \left(\frac{2}{10}\right)\left(\frac{3}{10}\right) = \frac{6}{100} \end{aligned}$$

6. COMPLEMENTARY PROBABILITIES

The probability of an event occurring is equal to one minus the probability of the event not occurring. This is known as *complementary probability*.

$$p\{e_i\} = 1 - p\{\text{not } e_i\} \qquad 11.26$$

Equation 11.26 can be used to simplify some probability calculations. Specifically, calculation of the probability of numerical events being "greater than" or "less than" or quantities being "at least" a certain number can often be simplified by calculating the probability of complementary event.

Example 11.7

A fair coin is tossed five times.[1] What is the probability of getting at least one tail?

Solution

The probability of getting at least one tail in five tosses could be calculated as

$$\begin{aligned} p\{\text{at least 1 tail}\} = {} & p\{1 \text{ tail}\} + p\{2 \text{ tails}\} \\ & + p\{3 \text{ tails}\} + p\{4 \text{ tails}\} \\ & + p\{5 \text{ tails}\} \end{aligned}$$

However, it is easier to calculate the complementary probability of getting no tails (i.e., getting all heads).

$$\begin{aligned} p\{\text{at least 1 tail}\} &= 1 - p\{0 \text{ tails}\} \\ &= 1 - (0.5)^5 = 0.96875 \end{aligned}$$

7. CONDITIONAL PROBABILITY

Given two dependent sets of events, E and G, the probability that event e_k will occur given the fact that the dependent event g has already occurred is written as $p\{e_k|g\}$ and given by *Bayes' theorem*, Eq. 11.27.

$$p\{e_k|g\} = \frac{p\{e_k \text{ and } g\}}{p\{g\}} = \frac{p\{g|e_k\}p\{e_k\}}{\sum_{i=1}^{n} p\{g|e_i\}p\{e_i\}} \qquad 11.27$$

[1]It makes no difference whether one coin is tossed five times or five coins are each tossed once.

8. PROBABILITY DENSITY FUNCTIONS

A *density function* is a nonnegative function whose integral taken over the entire range of the independent variable is unity. A *probability density function* (PDF) is a mathematical formula that gives the probability of a discrete numerical event. A *numerical event* is an occurrence that can be described (usually) by an integer. For example, 27 cars passing through a bridge toll booth in an hour is a discrete numerical event.

A probability density function, $f(x)$, gives the probability that discrete event x will occur. That is, $p\{x\} = f(x)$. Important discrete probability density functions are the binomial, hypergeometric, and Poisson distributions.

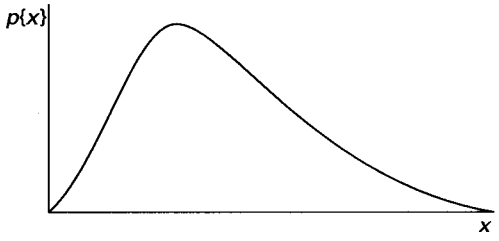

Figure 11.2 *Probability Density Function*

9. BINOMIAL DISTRIBUTION

The *binomial probability density function* is used when all outcomes can be categorized as either successes or failures. The probability of success in a single trial is $\hat{p}$, and the probability of failure is the complement, $\hat{q} = 1 - \hat{p}$. The population is assumed to be infinite in size so that sampling does not change the values of $\hat{p}$ and $\hat{q}$. (The binomial distribution can also be used with finite populations when sampling with replacement.)

Equation 11.28 gives the probability of x successes in n independent *successive trials*. The quantity $\binom{n}{x}$ is the binomial coefficient, identical to the number of combinations of n items taken x at a time.

$$p\{x\} = f(x) = \binom{n}{x}\hat{p}^x\hat{q}^{n-x} \qquad 11.28$$

$$\binom{n}{x} = \frac{n!}{(n-x)!x!} \qquad 11.29$$

Equation 11.28 is a true (discrete) distribution, taking on values for each integer value up to n. The mean, μ, and variance, σ^2 (see Secs. 18 and 19), of this distribution are

$$\mu = n\hat{p} \qquad 11.30$$

$$\sigma^2 = n\hat{p}\hat{q} \qquad 11.31$$

Example 11.8

Five percent of a large batch of high-strength steel bolts purchased for bridge construction are defective. (a) If seven bolts are randomly sampled, what is the probability that exactly three will be defective? (b) What is the probability that two or more bolts will be defective?

Solution

(a) The bolts are either defective or not, so the binomial distribution can be applied.

$$\hat{p} = 0.05$$
$$\hat{q} = 1 - 0.05 = 0.95$$

From Eq. 11.28,

$$p\{3\} = f(3) = \binom{7}{3}\hat{p}^3\hat{q}^{7-3}$$
$$= \left(\frac{7 \cdot 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1}{4 \cdot 3 \cdot 2 \cdot 1 \cdot 3 \cdot 2 \cdot 1}\right)(0.05)^3(0.95)^4$$
$$= 0.00356$$

(b) The probability that two or more bolts will be defective could be calculated as

$$p\{x \geq 2\} = p\{2\} + p\{3\} + p\{4\} + p\{5\} + p\{6\} + p\{7\}$$

This method would require six probability calculations. It is easier to use the complement of the desired probability.

$$p\{x \geq 2\} = 1 - p\{x \leq 1\} = 1 - [p\{0\} + p\{1\}]$$
$$p\{0\} = \binom{7}{0}(0.05)^0(0.95)^7 = (0.95)^7$$
$$p\{1\} = \binom{7}{1}(0.05)^1(0.95)^6 = (7)(0.05)(0.95)^6$$
$$p\{x \geq 2\} = 1 - [(0.95)^7 + (7)(0.05)(0.95)^6]$$
$$= 1 - [0.6983 + 0.2573]$$
$$= 0.0444$$

10. HYPERGEOMETRIC DISTRIBUTION

Probabilities associated with sampling from a finite population without replacement are calculated from the *hypergeometric distribution*. If a population of finite size M contains K items with a given characteristic (e.g., red color, defective construction), then the probability of finding x items with that characteristic in a sample of n items is

$$p\{x\} = f(x) = \frac{\binom{K}{x}\binom{M-K}{n-x}}{\binom{M}{n}} \quad [\text{for } x \leq n] \qquad 11.32$$

11. MULTIPLE HYPERGEOMETRIC DISTRIBUTION

Sampling without replacement from finite populations containing several different types of items is handled by the *multiple hypergeometric distribution*. If a population of finite size M contains K_i items of type i (such that $\sum K_i = M$), the probability of finding x_1 items of type 1, x_2 items of type 2, and so on, in a sample size n (such that $\sum x_i = n$) is

$$p\{x_1, x_2, x_3, \ldots\} = \frac{\binom{K_1}{x_1}\binom{K_2}{x_2}\binom{K_3}{x_3}\cdots}{\binom{M}{n}} \qquad 11.33$$

12. POISSON DISTRIBUTION

Certain events occur relatively infrequently but at a relatively regular rate. The probability of such an event occurring is given by the *Poisson distribution*. Suppose an event occurs, on the average, λ times per period. The probability that the event will occur x times per period is

$$p\{x\} = f(x) = \frac{e^{-\lambda}\lambda^x}{x!} \qquad [\lambda > 0] \qquad 11.34$$

λ is both the mean and the variance of the Poisson distribution.

Example 11.9

The number of customers arriving at a hamburger stand in the next period is a Poisson distribution having a mean of eight. What is the probability that exactly six customers will arrive in the next period?

Solution

$\lambda = 8$ and $x = 6$. From Eq. 11.34,

$$p\{6\} = \frac{e^{-\lambda}\lambda^x}{x!} = \frac{e^{-8}(8)^6}{6!} = 0.122$$

13. CONTINUOUS DISTRIBUTION FUNCTIONS

Most numerical events are *continuously distributed* and are not constrained to discrete or integer values. For example, the resistance of a 10% 1 Ω resistor may be any value between 0.9 and 1.1 Ω. The probability of an exact numerical event is zero for continuously distributed variables. That is, there is no chance that a numerical event will be *exactly* x.[2] It is possible to determine only the probability that a numerical event will be less than x, greater than x, or between the values of x_1 and x_2, but not exactly equal to x.

[2]It is important to understand the rationale behind this statement. Since the variable can take on any value and has an infinite number of significant digits, we can infinitely continue to increase the precision of the value. For example, the probability is zero that a resistance will be exactly 1 Ω because the resistance is really 1.03 or 1.0260008 or 1.02600080005, and so on.

While an expression, $f(x)$, for a probability density function can be written, it is used to derive the *continuous distribution function* (CDF), $F(x_0)$, which gives the probability of numerical event x_0 or less occurring.

$$p\{X < x_0\} = F(x_0) = \int_0^{x_0} f(x)dx \qquad 11.35$$

$$f(x) = \frac{dF(x)}{dx} \qquad 11.36$$

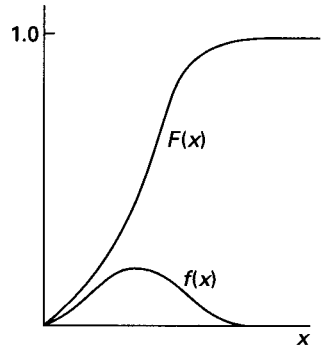

Figure 11.3 *Continuous Distribution Function*

14. EXPONENTIAL DISTRIBUTION

The continuous *exponential distribution* is given by its probability density and continuous distribution functions.

$$f(x) = \lambda e^{-\lambda x} \qquad 11.37$$

$$p\{X < x\} = F(x) = 1 - e^{-\lambda x} \qquad 11.38$$

The mean and variance of the exponential distribution are

$$\mu = \frac{1}{\lambda} \qquad 11.39$$

$$\sigma^2 = \frac{1}{\lambda^2} \qquad 11.40$$

15. NORMAL DISTRIBUTION

The *normal distribution (Gaussian distribution)* is a symmetrical distribution commonly referred to as the *bell-shaped curve*, which represents the distribution of outcomes of many experiments, processes, and phenomena. The probability density and continuous distribution functions for the normal distribution with mean μ and variance σ^2 are

$$f(x) = \frac{e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}}{\sigma\sqrt{2\pi}} \qquad [-\infty < x < +\infty] \qquad 11.41$$

$$p\{\mu < X < x_0\} = F(x_0) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^{x_0} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2} dx \qquad 11.42$$

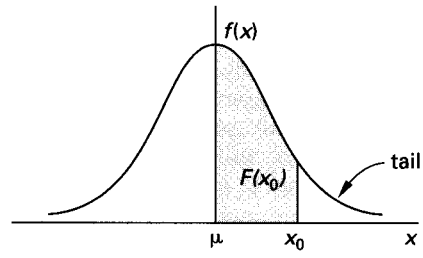

Figure 11.4 *Normal Distribution*

Since $f(x)$ is difficult to integrate, Eq. 11.41 is seldom used directly, and a *standard normal table* (see App. 11.A) is used instead. The standard normal table is based on a normal distribution with a mean of zero and a standard deviation of 1. Since the range of values from an experiment or phenomenon will not generally correspond to the standard normal table, a value, x_0, must be converted to a *standard normal value*, z. In Eq. 11.43, μ and σ are the mean and standard deviation, respectively, of the distribution from which x_0 comes. For all practical purposes, all normal distributions are completely bounded by $\mu \pm 3\sigma$.

$$z = \frac{x_0 - \mu}{\sigma} \qquad 11.43$$

Numbers in the standard normal table given by App. 11.A are the probabilities of the normalized x being between zero and z and represent the areas under the curve up to point z. When x is less than μ, z will be negative. However, the curve is symmetrical, so the table value corresponding to positive z can be used. The probability of x being greater than z is the complement of the table value. The curve area past point z is known as the *tail of the curve*.

The *error function*, $\text{erf}(x)$, and its complement, $\text{erfc}(x)$, are defined by Eqs. 11.44 and 11.45. The error function is used to determine the probable error of a measurement.

$$\text{erf}(x_0) = \frac{2}{\sqrt{\pi}} \int_0^{x_0} e^{-x^2} dx \qquad 11.44$$

$$\text{erfc}(x_0) = 1 - \text{erf}(x_0) \qquad 11.45$$

Example 11.10

The mass, m, of a particular hand-laid fiberglass (Fibreglas™) part is normally distributed with a mean of 66 kg and a standard deviation of 5 kg. (a) What percent of the parts will have a mass less than 72 kg? (b) What percent of the parts will have a mass in excess of 72 kg? (c) What percent of the parts will have a mass between 61 and 72 kg?

Solution

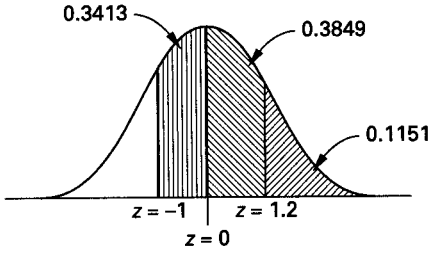
(a) The value of 72 kg must be normalized by using Eq. 11.43. The standard normal variable is

$$z = \frac{x - \mu}{\sigma} = \frac{72\ \text{kg} - 66\ \text{kg}}{5\ \text{kg}} = 1.2$$

Reading from App. 11.A, the area under the normal curve is 0.3849. This represents the probability of the mass, m, being between 66 kg and 72 kg (i.e., z being between 0 and 1.2). However, the probability of the mass being less than 66 kg is also needed. Since the curve is symmetrical, this probability is 0.5. Therefore,

$$p\{m < 72\ \text{kg}\} = p\{z < 1.2\} = 0.5 + 0.3849 = 0.8849$$

(b) The probability of the mass exceeding 72 kg is the area under the tail past point z.



$$p\{m > 72\ \text{kg}\} = p\{z > 1.2\} = 0.5 - 0.3849 = 0.1151$$

(c) The standard normal variable corresponding to $m = 61$ kg is

$$z = \frac{x - \mu}{\sigma} = \frac{61\ \text{kg} - 66\ \text{kg}}{5\ \text{kg}} = -1$$

Since the two masses are on opposite sides of the mean, the probability will have to be determined in two parts.

$$\begin{aligned} p\{61 < m < 72\} &= p\{61 < m < 66\} + p\{66 < m < 72\} \\ &= p\{-1 < z < 0\} + p\{0 < z < 1.2\} \\ &= 0.3413 + 0.3849 = 0.7262 \end{aligned}$$

16. APPLICATION: RELIABILITY

Introduction

Reliability, $R\{t\}$, is the probability that an item will continue to operate satisfactorily up to time t. The *bathtub distribution*, Fig. 11.5, is often used to model the probability of failure of an item (or, the number of failures from a large population of items) as a function of time. Items initially fail at a high rate, a phenomenon known as *infant mortality*. For the majority of the operating time, known as the *steady-state operation*, the failure rate is constant (i.e., is due to random causes). After a long period of time, the items begin to deteriorate and the failure rate increases. (No mathematical distribution describes all three of these phases simultaneously.)

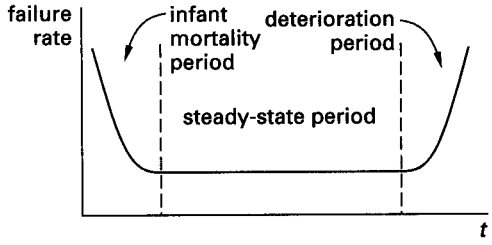


Figure 11.5 *Bathtub Reliability Curve*

The *hazard function*, $z\{t\}$, represents the *conditional probability of failure*—the probability of failure in the next time interval, given that no failure has occurred thus far.[3]

$$z\{t\} = \frac{f(t)}{R(t)} = \frac{\dfrac{dF(t)}{dt}}{1 - F(t)} \qquad 11.46$$

Exponential Reliability

Steady-state reliability is often described by the *negative exponential distribution*. This assumption is appropriate whenever an item fails only by random causes and does not experience deterioration during its life. The parameter λ is related to the *mean time to failure* (MTTF) of the item.[4]

$$R\{t\} = e^{-\lambda t} = e^{\frac{-t}{\text{MTTF}}} \qquad 11.47$$

$$\lambda = \frac{1}{\text{MTTF}} \qquad 11.48$$

Equation 11.47 and the exponential continuous distribution function, Eq. 11.38, are complementary.

$$R\{t\} = 1 - F(t) = 1 - (1 - e^{-\lambda t}) = e^{-\lambda t} \qquad 11.49$$

The hazard function for the negative exponential distribution is

$$z\{t\} = \lambda \qquad 11.50$$

Thus, the hazard function for exponential reliability is constant and does not depend on t (i.e., on the age of the item). In other words, the expected future life of an item is independent of the previous history (length of operation). This lack of memory is consistent with the assumption that only random causes contribute to failure during steady-state operations. And since random causes are unlikely discrete events, their probability of

[3]The symbol $z\{t\}$ is traditionally used for the hazard function and is not related to the standard normal variable.

[4]The term "mean time *between* failures" is improper. However, the term *mean time before failure* (MTBF) is acceptable.

occurrence can be represented by a Poisson distribution with mean λ. That is, the probability of having x failures in any given period is

$$p\{x\} = \frac{e^{-\lambda}\lambda^x}{x!} \qquad 11.51$$

Serial System Reliability

In the analysis of system reliability, the binary variable X_i is defined as one if item i operates satisfactorily and zero otherwise. Similarly, the binary variable Φ is one only if the entire system operates satisfactorily. Thus, Φ will depend on a *performance function* containing the X_i.

A *serial system* is one for which all items must operate correctly for the system to operate. Each item has its own reliability, R_i. For a serial system of n items, the performance function is

$$\Phi = X_1X_2X_3 \cdots X_n = \min(X_i) \qquad 11.52$$

The probability of a serial system operating correctly is

$$p\{\Phi = 1\} = R_{\text{serial system}} = R_1R_2R_3 \cdots R_n \qquad 11.53$$

Parallel System Reliability

A *parallel system* with n items will fail only if all n items fail. Such a system is said to be *redundant* to the nth degree. Using redundancy, a highly reliable system can be produced from components with relatively low individual reliabilities.

The performance function of a redundant system is

$$\begin{aligned}\Phi &= 1 - (1 - X_1)(1 - X_2)(1 - X_3)\cdots(1 - X_n) \\ &= \max(X_i)\end{aligned} \qquad 11.54$$

The reliability of the parallel system is

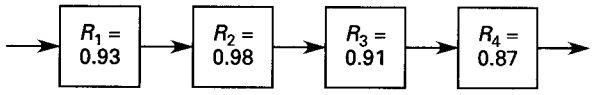
$$R = p\{\Phi = 1\} = 1-(1-R_1)(1-R_2)(1-R_3)\cdots(1-R_n) \qquad 11.55$$

Example 11.11

The reliability of an item is exponentially distributed with mean time to failure (MTTF) of 1000 hr. What is the probability that the item will not have failed after 1200 hr of operation?

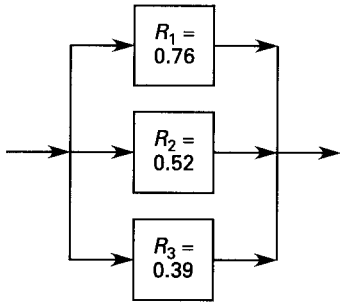
Solution

The probability of not having failed before time t is the reliability. From Eqs. 11.48 and 11.49,



$$\lambda = \frac{1}{\text{MTTF}} = \frac{1}{1000\,\text{hr}} = 0.001$$

$$R\{1200\} = e^{-\lambda t} = e^{(-0.001)(1200\ \text{hr})} = 0.3$$



Example 11.12

What are the reliabilities of the following systems?

(a)

(b)

Solution

(a) This is a serial system. From Eq. 11.53,

$$\begin{aligned}R &= R_1R_2R_3R_4 = (0.93)(0.98)(0.91)(0.87) \\ &= 0.72\end{aligned}$$

(b) This is a parallel system. From Eq. 11.55,

$$\begin{aligned}R &= 1 - (1 - R_1)(1 - R_2)(1 - R_3) \\ &= 1 - (1 - 0.76)(1 - 0.52)(1 - 0.39) = 0.93\end{aligned}$$

17. ANALYSIS OF EXPERIMENTAL DATA

Experiments can take on many forms. An experiment might consist of measuring the mass of one cubic foot of concrete, or measuring the speed of a car on a roadway. Generally, such experiments are performed more than once to increase the precision and accuracy of the results.

Both systematic and random variations in the process being measured will cause the observations to vary, and the experiment would not be expected to yield the same

result each time it was performed. Eventually, a collection of experimental outcomes (observations) will be available for analysis.

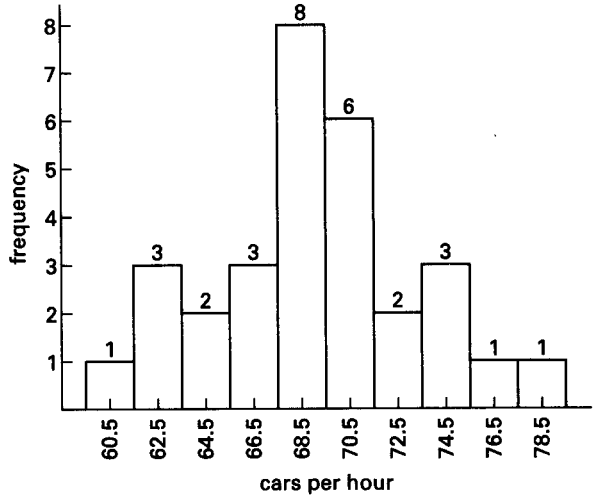
The *frequency distribution* is a systematic method for ordering the observations from small to large, according to some convenient numerical characteristic. The *step interval* should be chosen so that the data are presented in a meaningful manner. If there are too many intervals, many of them will have zero frequencies; if there are too few intervals, the frequency distribution will have little value. Generally, 10 to 15 intervals are used.

Once the frequency distribution is complete, it can be represented graphically as a *histogram*. The procedure in drawing a histogram is to mark off the interval limits (also known as *class limits*) on a number line and then draw contiguous bars with lengths that are proportional to the frequencies in the intervals and that are centered on the midpoints of their respective intervals. The continuous nature of the data can be depicted by a *frequency polygon*. The number or percentage of observations that occur up to and including some value can be shown in a *cumulative frequency table*.

Example 11.13

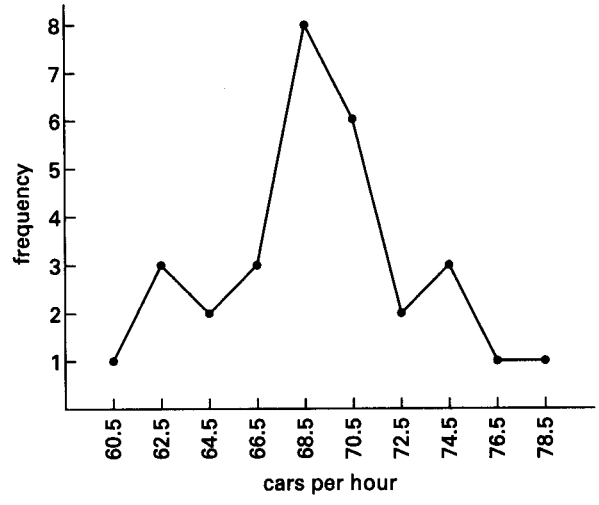
The number of cars that travel through an intersection between 12 noon and 1 p.m. is measured for 30 consecutive working days. The results of the 30 observations are

79, 66, 72, 70, 68, 66, 68, 76, 73, 71, 74, 70, 71, 69, 67, 74, 70, 68, 69, 64, 75, 70, 68, 69, 64, 69, 62, 63, 63, 61



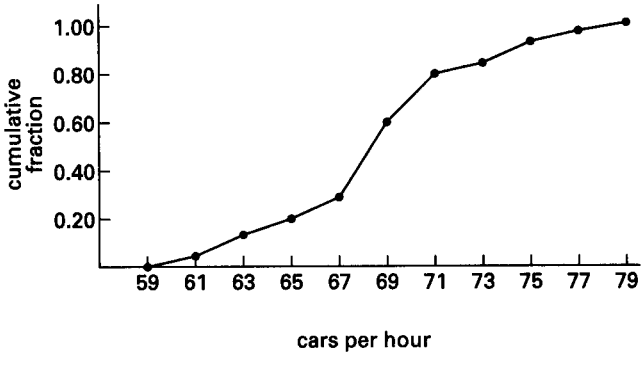
(a) What are the frequency and cumulative distributions? (Use a distribution interval of two cars per hour.) (b) Draw the histogram. (Use a cell size of two cars per hour.) (c) Draw the frequency polygon. (d) Graph the cumulative frequency distribution.

Solution



(a)

cars per hour	frequency	cumulative frequency	cumulative percent
60–61	1	1	3
62–63	3	4	13
64–65	2	6	20
66–67	3	9	30
68–69	8	17	57
70–71	6	23	77
72–73	2	25	83
74–75	3	28	93
76–77	1	29	97
78–79	1	30	100



(b)

(c)

(d)

18. MEASURES OF CENTRAL TENDENCY

It is often unnecessary to present the experimental data in their entirety, either in tabular or graphical form. In such cases, the data and distribution can be represented by various parameters. One type of parameter is a measure of *central tendency*. Mode, median, and mean are measures of central tendency.

The *mode* is the observed value that occurs most frequently. The mode may vary greatly between series of observations. Therefore, its main use is as a quick measure of the central value since little or no computation is required to find it. Beyond this, the usefulness of the mode is limited.

The *median* is the point in the distribution that partitions the total set of observations into two parts containing equal numbers of observations. It is not influenced by the extremity of scores on either side of the distribution. The median is found by counting up (from either end of the frequency distribution) until half of the observations have been accounted for.

Similar in concept to the median are *percentiles (percentile ranks), quartiles,* and *deciles.* The median could also have been called the *50th percentile* observation. Similarly, the 80th percentile would be the observed value (e.g., the number of cars per hour) for which the cumulative frequency was 80%. The quartile and decile points on the distribution divide the observations or distribution into segments of 25% and 10%, respectively.

The *arithmetic mean* is the arithmetic average of the observations. The sample mean, $\bar{x}$, can be used as an unbiased estimator of the population mean, μ. The *mean* may be found without ordering the data (as was necessary to find the mode and median). The mean can be found from the following formula.

$$\bar{x} = \left(\frac{1}{n}\right)(x_1 + x_2 + \cdots + x_n) = \frac{\sum x_i}{n} \qquad 11.56$$

The *geometric mean* is used occasionally when it is necessary to average ratios. The geometric mean is calculated as

$$\text{geometric mean} = \sqrt[n]{x_1 x_2 x_3 \cdots x_n} \quad [x_i > 0] \qquad 11.57$$

The *harmonic mean* is defined as

$$\text{harmonic mean} = \frac{n}{\frac{1}{x_1} + \frac{1}{x_2} + \cdots + \frac{1}{x_n}} \qquad 11.58$$

The *root-mean-squared* (rms) *value* of a series of observations is defined as

$$x_{\text{rms}} = \sqrt{\frac{\sum x_i^2}{n}} \qquad 11.59$$

Example 11.14

Find the mode, median, and arithmetic mean of the distribution represented by the data given in Ex. 11.13.

Solution

The mode is the interval 68–69, since this interval has the highest frequency. If 68.5 is taken as the interval center, then 68.5 would be the mode.

Since there are 30 observations, the median is the value that separates the observations into two groups of 15. From Ex. 11.13, the median occurs someplace within the 68–69 interval. Up through interval 66–67, there are nine observations, so six more are needed to make 15. Interval 68–69 has eight observations, so the median is found to be 6/8 or 3/4 of the way through the interval. Since the real limits of the interval are 67.5 and 69.5, the median is located at

$$67.5 + \left(\tfrac{3}{4}\right)(69.5 - 67.5) = 69$$

The mean can be found from the raw data or from the grouped data using the interval center as the assumed observation value. Using the raw data,

$$\bar{x} = \frac{\sum x}{n} = \frac{2069}{30} = 68.97$$

19. MEASURES OF DISPERSION

The simplest statistical parameter that describes the variability in observed data is the *range.* The range is found by subtracting the smallest value from the largest. Since the range is influenced by extreme (low probability) observations, its use as a measure of variability is limited.

The *standard deviation* is a better estimate of variability because it considers every observation. That is, N in Eq. 11.60 is the total population size, not the sample size, n.

$$\sigma = \sqrt{\frac{\sum (x_i - \mu)^2}{N}} = \sqrt{\frac{\sum x_i^2}{N} - \mu^2} \qquad 11.60$$

The standard deviation of a sample (particularly a small sample) is a biased (i.e., is not a good) estimator of the population standard deviation. An *unbiased estimator* of the population standard deviation is the *sample standard deviation*, s.[5]

$$s = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}} = \sqrt{\frac{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}{n-1}} \qquad 11.61$$

[5]There is a subtle yet significant difference between *standard deviation of the sample*, σ (obtained from Eq. 11.60 for a finite sample drawn from a larger population) and the *sample standard deviation*, s (obtained from Eq. 11.61). While σ can be calculated, it has no significance or use as an estimator. It is true that the difference between σ and s approaches zero when the sample size, n, is large, but this convergence does nothing to legitimize the use of σ as an estimator of the true standard deviation. (Some people say "large" is 30, others say 50 or 100.)

If the sample standard deviation, s, is known, the standard deviation of the sample, σ_{sample}, can be calculated.

$$\sigma_{\text{sample}} = s\sqrt{\frac{n-1}{n}} \qquad 11.62$$

The *variance* is the square of the standard deviation. Since there are two standard deviations, there are two variances. The *variance of the sample* is σ^2, and the *sample variance* is s^2.

The *relative dispersion* is defined as a measure of dispersion divided by a measure of central tendency. The *coefficient of variation* is a relative dispersion calculated from the sample standard deviation and the mean.

$$\text{coefficient of variation} = \frac{s}{\bar{x}} \qquad 11.63$$

Skewness is a measure of a frequency distribution's lack of symmetry.

$$\begin{aligned}\text{skewness} &= \frac{\bar{x} - \text{mode}}{s} \\ &\approx \frac{3(\bar{x} - \text{median})}{s}\end{aligned} \qquad 11.64$$

Example 11.15

For the data given in Ex. 11.13, calculate (a) the sample range, (b) the standard deviation of the sample, (c) an unbiased estimator of the population standard deviation, (d) the variance of the sample, and (e) the sample variance.

Solution

$$\begin{aligned}\sum x_i &= 2069 \\ \left(\sum x_i\right)^2 &= (2069)^2 = 4{,}280{,}761 \\ \sum x_i^2 &= 143{,}225 \\ n &= 30 \\ \bar{x} &= \frac{2069}{30} = 68.967\end{aligned}$$

(a) $R = x_{\max} - x_{\min} = 79 - 61 = 18$

(b) $\sigma = \sqrt{\dfrac{\sum x_i^2}{n} - (\bar{x})^2} = \sqrt{\dfrac{143{,}225}{30} - \left(\dfrac{2069}{30}\right)^2}$

$= \sqrt{17.766} = 4.215$

(c) $s = \sqrt{\dfrac{\sum x_i^2 - \dfrac{\left(\sum x_i\right)^2}{n}}{n-1}} = \sqrt{\dfrac{143{,}225 - \dfrac{4{,}280{,}761}{30}}{29}}$

$= \sqrt{18.378} = 4.287$

(d) $\sigma^2 = 17.77$

(e) $s^2 = 18.38$

20. CENTRAL LIMIT THEOREM

Measuring a sample of n items from a population with mean μ and standard deviation σ is the general concept of an experiment. The sample mean, $\bar{x}$, is one of the parameters that can be derived from the experiment. This experiment can be repeated k times, yielding a set of averages $(\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_k)$. The k numbers in the set themselves represent samples from distributions of averages. The average of averages, $\bar{\bar{x}}$, and sample standard deviation of averages, $s_{\bar{x}}$ (known as the *standard error of the mean*), can be calculated.

The *central limit theorem* defines the mean of the sample averages. The theorem can be stated in several ways, but the essential elements are the following points.

(1) The averages, $\bar{x}_i$, are normally distributed variables, even if the original data from which they are calculated are not normally distributed.

(2) The grand average, $\bar{\bar{x}}$ (i.e., the average of the averages), approaches and is an unbiased estimator of μ.

$$\mu \approx \bar{\bar{x}} \qquad 11.65$$

The standard deviation of the original distribution, σ, is much larger than the standard error of the mean.

$$\sigma \approx \sqrt{n} s_{\bar{x}} \qquad 11.66$$

21. CONFIDENCE LEVEL

The results of experiments are seldom correct 100% of the time. Recognizing this, researchers accept a certain probability of being wrong. In order to minimize this probability, the experiment is repeated several times. The number of repetitions depends on the desired level of confidence in the results.

If the results have a 5% probability of being wrong, the *confidence level*, C, is 95% that the results are correct, in which case the results are said to be *significant*. If the results have only a 1% probability of being wrong, the confidence level is 99%, and the results are said to be *highly significant*. Other confidence levels (90%, 99.5%, etc.) are used as appropriate.

22. APPLICATION: CONFIDENCE LIMITS

As a consequence of the central limit theorem, sample means of n items taken from a normal distribution with mean μ and standard deviation σ will be normally distributed with mean μ and variance σ^2/n. Thus, the probability that any given average, $\bar{x}$, exceeds some value, L, is

$$p\{\bar{x} > L\} = p\left\{z > \left|\frac{L-\mu}{\frac{\sigma}{\sqrt{n}}}\right|\right\} \qquad 11.67$$

L is the *confidence limit* for the confidence level $1 - p\{\bar{x} > L\}$ (expressed as a percent). Values of z are read directly from the standard normal table. As an example, $z = 1.645$ for a 95% confidence level since only 5% of the curve is above that z in the upper tail. Similar values are given in Table 11.1. This is known as a *one-tail confidence limit* because all of the probability is given to one side of the variation.

Table 11.1 *Values of z for Various Confidence Levels*

confidence level, C	one-tail limit z	two-tail limit z
90%	1.28	1.645
95%	1.645	1.96
97.5%	1.96	2.17
99%	2.33	2.575
99.5%	2.575	2.81
99.75%	2.81	3.00

With *two-tail confidence limits*, the probability is split between the two sides of variation. There will be upper and lower confidence limits, UCL and LCL, respectively.

$$p\{\text{LCL} < \bar{x} < \text{UCL}\} = p\left\{\frac{\text{LCL} - \mu}{\frac{\sigma}{\sqrt{n}}} < z < \frac{\text{UCL} - \mu}{\frac{\sigma}{\sqrt{n}}}\right\} \quad 11.68$$

23. APPLICATION: BASIC HYPOTHESIS TESTING

A *hypothesis test* is a procedure that answers the question, "Did these data come from [a particular type of] distribution?" There are many types of tests, depending on the distribution and parameter being evaluated. The simplest hypothesis test determines whether an average value obtained from n repetitions of an experiment could have come from a population with known mean, μ, and standard deviation, σ. A practical application of this question is whether a manufacturing process has changed from what it used to be or should be. Of course, the answer (i.e., "yes" or "no") cannot be given with absolute certainty—there will be a confidence level associated with the answer.

The following procedure is used to determine whether the average of n measurements can be assumed (with a given confidence level) to have come from a known population.

step 1: Assume random sampling from a normal population.

step 2: Choose the desired confidence level, C.

step 3: Decide on a one-tail or two-tail test. If the hypothesis being tested is that the average has or has not *increased* or *decreased*, choose a one-tail test. If the hypothesis being tested is that the average has or has not *changed*, choose a two-tail test.

step 4: Use Table 11.1 or the standard normal table to determine the z-value corresponding to the confidence level and number of tails.

step 5: Calculate the actual standard normal variable, z'.

$$z' = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} \quad 11.69$$

step 6: If $z' \geq z$, the average can be assumed (with confidence level C) to have come from a different distribution.

Example 11.16

When it is operating properly, a cement plant has a daily production rate that is normally distributed with a mean of 880 tons/day and a standard deviation of 21 tons/day. During an analysis period, the output is measured on 50 consecutive days, and the mean output is found to be 871 tons/day. With a 95% confidence level, determine whether the plant is operating properly.

Solution

step 1: Given.

step 2: $C = 0.95$ is given.

step 3: Since a specific direction in the variation is not given (i.e., the example does not ask whether the average has decreased), use a two-tail hypothesis test.

step 4: From Table 11.1, $z = 1.96$.

step 5: From Eq. 11.69,

$$z' = \left|\frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}}\right| = \left|\frac{871 - 880}{\frac{21}{\sqrt{50}}}\right| = 3.03$$

Since $3.03 > 1.96$, the distributions are not the same. There is at least a 95% probability that the plant is not operating correctly.

24. APPLICATION: STATISTICAL PROCESS CONTROL

All manufacturing processes contain variation due to random and nonrandom causes. Random variation cannot be eliminated. *Statistical process control* (SPC) is the act of monitoring and adjusting the performance of a process to detect and eliminate nonrandom variation.

Statistical process control is based on taking regular (hourly, daily, etc.) samples of n items and calculating the mean, $\bar{x}$, and range, R, of the sample. To simplify the calculations, the range is used as a measure of the dispersion. These two parameters are graphed on their respective x-bar and *R-control charts*.[6] Confidence limits are drawn at $\pm 3\sigma/\sqrt{n}$. From a statistical standpoint, the control chart tests a hypothesis each time a point is plotted. When a point falls outside these limits, there is a 99.75% probability that the process is out of control. Until a point exceeds the control limits, no action is taken.[7]

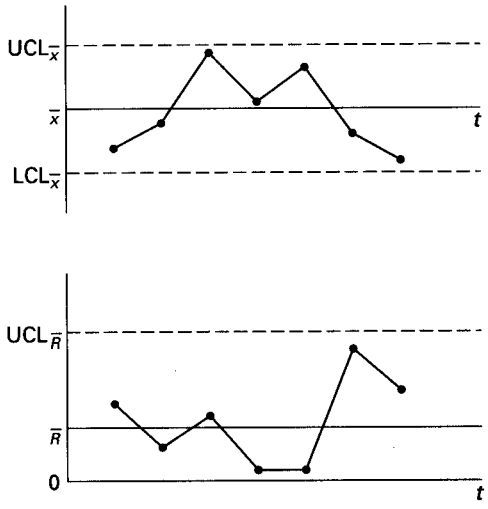


Figure 11.6 *Typical Statistical Process Control Charts*

25. MEASURES OF EXPERIMENTAL ADEQUACY

An experiment is said to be *accurate* if it is unaffected by experimental error. In this case, *error* is not synonymous with *mistake*, but rather includes all variations not within the experimenter's control.

For example, suppose a gun is aimed at a point on a target and five shots are fired. The mean distance from the point of impact to the sight in point is a measure of the alignment accuracy between the barrel and sights. The difference between the actual value and the experimental value is known as *bias*.

Precision is not synonymous with accuracy. Precision is concerned with the repeatability of the experimental results. If an experiment is repeated with identical results, the experiment is said to be precise.

The average distance of each impact from the centroid of the impact group is a measure of the precision of the experiment. Thus, it is possible to have a highly precise experiment with a large bias.

Most of the techniques applied to experiments in order to improve the accuracy of the experimental results (e.g., repeating the experiment, refining the experimental methods, or reducing variability) actually increase the precision.

Sometimes the word *reliability* is used with regard to the precision of an experiment. Thus, a "reliable estimate" is used in the same sense as a "precise estimate."

Stability and *insensitivity* are synonymous terms. A stable experiment will be insensitive to minor changes in the experimental parameters. For example, suppose the centroid of a bullet group is 2.1 in from the target point at 65°F and 2.3 in away at 80°F. The sensitivity of the experiment to temperature change would be

$$\text{sensitivity} = \frac{\Delta x}{\Delta T} = \frac{2.3\text{ in} - 2.1\text{ in}}{80^\circ\text{F} - 65^\circ\text{F}} = 0.0133\text{ in/}^\circ\text{F}$$

26. LINEAR REGRESSION

If it is necessary to draw a straight line ($y = mx + b$) through n data points $(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)$, the following method based on the *method of least squares* can be used.

step 1: Calculate the following nine quantities.

$$\sum x_i \quad \sum x_i^2 \quad \left(\sum x_i\right)^2 \quad \bar{x} = \frac{\sum x_i}{n} \quad \sum x_i y_i$$
$$\sum y_i \quad \sum y_i^2 \quad \left(\sum y_i\right)^2 \quad \bar{y} = \frac{\sum y_i}{n}$$

step 2: Calculate the slope, m, of the line.

$$m = \frac{n\sum(x_i y_i) - (\sum x_i)(\sum y_i)}{n\sum x_i^2 - (\sum x_i)^2} \qquad 11.70$$

step 3: Calculate the y-intercept, b.

$$b = \bar{y} - m\bar{x} \qquad 11.71$$

step 4: To determine the goodness of fit, calculate the correlation coefficient, r.

$$r = \frac{n\sum(x_i y_i) - (\sum x_i)(\sum y_i)}{\sqrt{[n\sum x_i^2 - (\sum x_i)^2][n\sum y_i^2 - (\sum y_i)^2]}} \qquad 11.72$$

If m is positive, r will be positive; if m is negative, r will be negative. As a general rule, if the absolute value of r exceeds 0.85, the fit is good; otherwise, the fit is poor. r equals 1.0 if the fit is a perfect straight line.

[6] Other charts (e.g., the *sigma chart, p-chart*, and *c-chart*) are less common but are used as required.

[7] Other indications that a correction may be required are seven measurements on one side of the average and seven consecutively increasing measurements. Rules such as these detect shifts and trends.

A low value of r does not eliminate the possibility of a nonlinear relationship existing between x and y. It is possible that the data describe a parabolic, logarithmic, or other nonlinear relationship. (Usually this will be apparent if the data are graphed.) It may be necessary to convert one or both variables to new variables by taking squares, square roots, cubes, or logarithms, to name a few of the possibilities, in order to obtain a linear relationship. The apparent shape of the line through the data will give a clue to the type of variable transformation that is required. The curves in Fig. 11.7 may be used as guides to some of the simpler variable transformations.

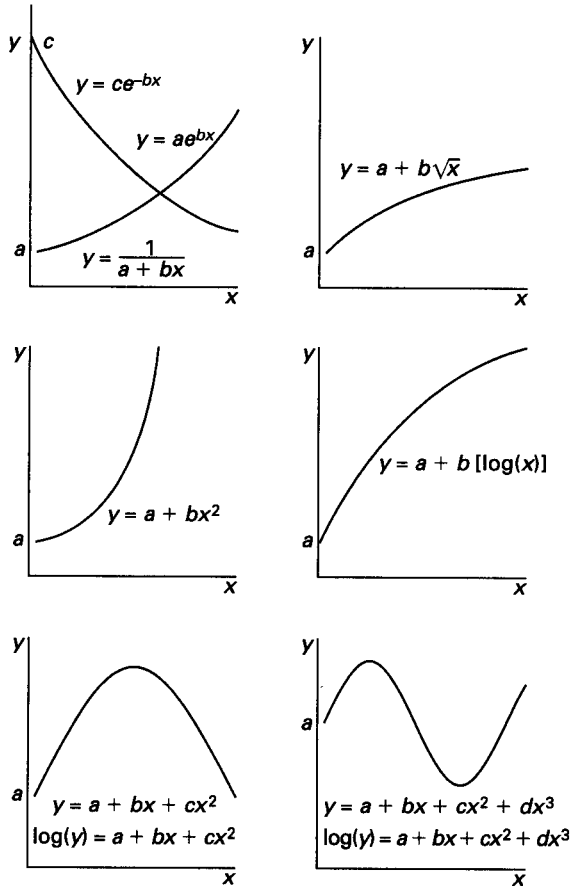

Figure 11.7 *Nonlinear Data Curves*

Figure 11.8 illustrates several common problems encountered in trying to fit and evaluate curves from experimental data. Figure 11.8(a) shows a graph of clustered data with several extreme points. There will be moderate correlation due to the weighting of the extreme points, although there is little actual correlation at low values of the variables. The extreme data should be excluded, or the range should be extended by obtaining more data.

Figure 11.8(b) shows that good correlation exists in general, but extreme points are missed and the overall correlation is moderate. If the results within the small linear range can be used, the extreme points should be excluded. Otherwise, additional data points are needed, and curvilinear relationships should be investigated.

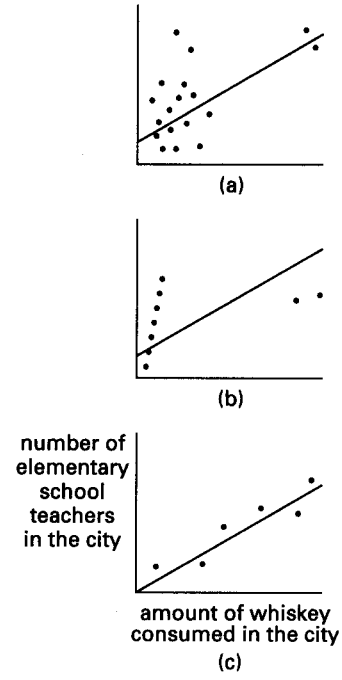

Figure 11.8 *Common Regression Difficulties*

Figure 11.8(c) illustrates the problem of drawing conclusions of cause and effect. There may be a predictable relationship between variables, but that does not imply a cause and effect relationship. In the case shown, both variables are functions of a third variable, the city population. But there is no direct relationship between the plotted variables.

Example 11.17

An experiment is performed in which the dependent variable y is measured against the independent variable x. The results are as follows.

x	y
1.2	0.602
4.7	5.107
8.3	6.984
20.9	10.031

(a) What is the least squares straight line equation that represents this data? (b) What is the correlation coefficient?

Solution

(a)

$$\sum x_i = 35.1$$

$$\sum y_i = 22.72$$

$$\sum x_i^2 = 529.23$$
$$\sum y_i^2 = 175.84$$
$$\left(\sum x_i\right)^2 = 1232.01$$
$$\left(\sum y_i\right)^2 = 516.38$$
$$\bar{x} = 8.775$$
$$\bar{y} = 5.681$$
$$\sum x_i y_i = 292.34$$
$$n = 4$$

From Eq. 11.70, the slope is

$$m = \frac{(4)(292.34) - (35.1)(22.72)}{(4)(529.23) - (35.1)^2} = 0.42$$

From Eq. 11.71, the y-intercept is

$$b = 5.681 - (0.42)(8.775) = 2.0$$

The equation of the line is

$$y = 0.42x + 2.0$$

(b) From Eq. 11.72, the correlation coefficient is

$$r = \frac{(4)(292.34) - (35.1)(22.72)}{\sqrt{\begin{array}{c}[(4)(529.23) - 1232.01] \\ \times [(4)(175.84) - 516.38]\end{array}}} = 0.914$$

Example 11.18

Repeat Ex. 11.17 assuming the relationship between the variables is nonlinear.

Solution

The first step is to graph the data. Since the graph has the appearance of the fourth case, it can be assumed that the relationship between the variables has the form of $y = a + b[\log(x)]$. Therefore, the variable change $z = \log(x)$ is made, resulting in the following set of data.

z	y
0.0792	0.602
0.672	5.107
0.919	6.984
1.32	10.031

If the regression analysis is performed on this set of data, the resulting equation and correlation coefficient are

$$y = -0.036 + 7.65z$$
$$r = 0.999$$

This is a very good fit. The relationship between the variable x and y is approximately

$$y = -0.036 + 7.65\log(x)$$

PRACTICE PROBLEMS

Probability

1. Four military recruits whose respective shoe sizes are 7, 8, 9, and 10 report to the supply clerk to be issued boots. The supply clerk selects one pair of boots in each of the four required sizes and hands them at random to the recruits.

(a) What is the probability that all recruits will receive boots of an incorrect size?

(A) 0.25
(B) 0.38
(C) 0.45
(D) 0.61

The answer is (B).

(b) What is the probability that exactly three recruits will receive boots of the correct size?

(A) 0
(B) 0.063
(C) 0.17
(D) 0.25

The answer is (A).

Probability Distributions

2. The time taken by a toll taker to collect the toll from vehicles crossing a bridge is an exponential distribution with a mean of 23 sec. What is the probability that a random vehicle will be processed in 25 sec or more (i.e., will take longer than 25 sec)?

(A) 0.17
(B) 0.25
(C) 0.34
(D) 0.52

The answer is (C).

3. The number of cars entering a toll plaza on a bridge during the hour after midnight follows a Poisson distribution with a mean of 20.

(a) What is the probability that 17 cars will pass through the toll plaza during that hour on any given night?

(A) 0.076
(B) 0.12
(C) 0.16
(D) 0.23

The answer is (A).

(b) What is the probability that three or fewer cars will pass through the toll plaza at that hour on any given night?

(A) 0.00032
(B) 0.0019
(C) 0.079
(D) 0.11

The answer is (A).

4. A mechanical component exhibits a negative exponential failure distribution with a mean time to failure of 1000 hr. What is the maximum operating time such that the reliability remains above 99%?

(A) 3.3 hr
(B) 5.6 hr
(C) 8.1 hr
(D) 10 hr

The answer is (D).

5. (*Time limit: one hour*) A survey field crew measures one leg of a traverse four times. The following results are obtained.

repetition	measurement	direction
1	1249.529	forward
2	1249.494	backward
3	1249.384	forward
4	1249.348	backward

The crew chief is under orders to obtain readings with confidence limits of 90%.

(a) Which readings are acceptable?

(A) No readings are acceptable.
(B) Two readings are acceptable.
(C) Three readings are acceptable.
(D) All four readings are acceptable.

The answer is (D).

(b) Which readings are not acceptable?

(A) No readings are unacceptable.
(B) One reading is unacceptable.
(C) Two readings are unacceptable.
(D) All four readings are unacceptable.

The answer is (A).

(c) Explain how to determine which readings are not acceptable.

(A) Readings inside the 90% confidence limits are unacceptable.
(B) Readings outside the 90% confidence limits are unacceptable.
(C) Readings outside the upper 90% confidence limit are unacceptable.
(D) Readings outside the lower 90% confidence limit are unacceptable.

The answer is (B).

(d) What is the most probable value of the distance?

(A) 1249.399
(B) 1249.410
(C) 1249.439
(D) 1249.452

The answer is (C).

(e) What is the error in the most probable value (at 90% confidence)?

(A) 0.08
(B) 0.11
(C) 0.14
(D) 0.19

The answer is (C).

(f) If the distance is one side of a square traverse whose sides are all equal, what is the most probable closure error?

(A) 0.14
(B) 0.20
(C) 0.28
(D) 0.35

The answer is (C).

(g) What is the probable error of part (f) expressed as a fraction?

(A) 1:17,600
(B) 1:14,200
(C) 1:12,500
(D) 1:10,900

The answer is (A).

(h) What is the order of accuracy of the closure?

(A) first order
(B) second order
(C) third order
(D) fourth order

The answer is (C).

(i) Define accuracy and distinguish it from precision.

(A) If an experiment can be repeated with identical results, the results are considered accurate.

(B) If an experiment has a small bias, the results are considered precise.

(C) If an experiment is precise, it cannot also be accurate.

(D) If an experiment is unaffected by experimental error, the results are accurate.

The answer is (D).

(j) Give an example of systematic error.

(A) measuring river depth as a motorized ski boat passes by

(B) using a steel tape that is too short to measure consecutive distances

(C) locating magnetic north near a large iron ore deposit along an overland route

(D) determining local wastewater BOD after a toxic spill

The answer is (B).

Statistical Analysis

6. *(Time limit: one hour)* California law requires a statistical analysis of the average speed driven by motorists on a road prior to the use of radar speed control. The following speeds (all in mi/hr) were observed in a random sample of 40 cars.

44, 48, 26, 25, 20, 43, 40, 42, 29, 39, 23, 26, 24, 47, 45, 28, 29, 41, 38, 36, 27, 44, 42, 43, 29, 37, 34, 31, 33, 30, 42, 43, 28, 41, 29, 36, 35, 30, 32, 31

(a) Tabulate the frequency distribution of the data.

(b) Draw the frequency histogram.

(c) Draw the frequency polygon.

(d) Tabulate the cumulative frequency distribution.

(e) Draw the cumulative frequency graph.

(f) What is the upper quartile speed?

(A) 30 mph

(B) 35 mph

(C) 40 mph

(D) 45 mph

The answer is (C).

(g) What is the median speed?

(A) 31 mph

(B) 33 mph

(C) 35 mph

(D) 37 mph

The answer is (B).

(h) What is the standard deviation of the sample data?

(A) 2.1 mph

(B) 6.1 mph

(C) 6.8 mph

(D) 7.4 mph

The answer is (D).

(i) What is the sample standard deviation?

(A) 7.5 mph

(B) 18 mph

(C) 35 mph

(D) 56 mph

The answer is (A).

(j) What is the sample variance?

(A) 56 mi^2/hr^2

(B) 324 mi^2/hr^2

(C) 1225 mi^2/hr^2

(D) 3136 mi^2/hr^2

The answer is (A).

7. A spot speed study is conducted for a stretch of roadway. During a normal day, the speeds were found to be normally distributed with a mean of 46 and a standard deviation of 3.

(a) What is the 50th percentile speed?

(A) 39

(B) 43

(C) 46

(D) 49

The answer is (C).

(b) What is the 85th percentile speed?

(A) 47.1

(B) 48.3

(C) 49.1

(D) 52.7

The answer is (C).

(c) What is the upper two standard deviation speed?

(A) 47.2

(B) 49.3

(C) 51.1

(D) 52.0

The answer is (D).

(d) The daily average speeds for the same stretch of roadway on consecutive normal days were determined by sampling 25 vehicles each day. What is the upper two-standard deviation average speed?

(A) 46.6

(B) 47.2

(C) 52.0

(D) 54.7

The answer is (B).

8. The diameters of bolt holes drilled in structural steel members are normally distributed with a mean of 0.502 in and a standard deviation of 0.005 in. Holes are out of specification if their diameters are less than 0.497 in or more than 0.507 in.

(a) What is the probability that a hole chosen at random will be out of specification?

(A) 0.16
(B) 0.22
(C) 0.32
(D) 0.68

The answer is (C).

(b) What is the probability that 2 holes out of a sample of 15 will be out of specification?

(A) 0.074
(B) 0.12
(C) 0.15
(D) 0.32

The answer is (A).

Hypothesis Testing

9. 100 bearings were tested to failure. The average life was 1520 hr, and the standard deviation was 120 hr. The manufacturer claims a 1600 hr life. Evaluate using confidence limits of 95% and 99%.

(A) The claim is accurate at both 95% and 99% confidence.
(B) The claim is inaccurate only at 95%.
(C) The claim is inaccurate only at 99%.
(D) The claim is inaccurate at both 95% and 99% confidence.

The answer is (D).

Curve Fitting

10. (a) Find the best equation for a line passing through the points given. (b) Find the correlation coefficient.

x	y
400	370
800	780
1250	1210
1600	1560
2000	1980
2500	2450
4000	3950

Answers: (a) $y = 0.994x - 25.0$; (b) $r \approx 1.00$

11. Find the best equation for a line passing through the points given.

s	t
20	43
18	141
16	385
14	1099

Answer: $\ln t = 14.527 - 0.536s$

12. The number of vehicles lining up behind a flashing railroad crossing has been observed for five trains of different lengths, as given. What is the mathematical formula that relates the two variables?

no. of cars in train	no. of vehicles
2	14.8
5	18.0
8	20.4
12	23.0
27	29.9

Answer: $y = 9.570 + 13.20 \log x$ or $y = 9.1 + 4\sqrt{x}$

13. The following yield data are obtained from five identical treatment plants. (a) Develop a mathematical equation to correlate the yield and average temperature. (b) What is the correlation coefficient?

treatment plant	average temperature (T)	average yield (Y)
1	207.1	92.30
2	210.3	92.58
3	200.4	91.56
4	201.1	91.63
5	203.4	91.83

Answers: (a) $Y = 0.106T + 70.4$; (b) $r = 0.995$

14. The following data are obtained from a soil compaction test. What is the mathematical formula that relates the two variables?

x	y
−1	0
0	1
1	1.4
2	1.7
3	2
4	2.2
5	2.4
6	2.6
7	2.8
8	3

Answer: $y = \sqrt{x+1}$

15. Two resistances, the meter resistance and a shunt resistor, are connected in parallel in an ammeter. Most of the current passing through the meter goes through the shunt resistor. In order to determine the accuracy of the resistance of shunt resistors being manufactured for a line of ammeters, a manufacturer tests a sample of 100 shunt resistors. The numbers of shunt resistors with the resistance indicated (to the nearest hundredth of an ohm) are as follows.

0.200 Ω, 1; 0.210 Ω, 3; 0.220 Ω, 5; 0.230 Ω, 10; 0.240 Ω, 17; 0.250 Ω, 40; 0.260 Ω, 13; 0.270 Ω, 6; 0.280 Ω, 3; 0.290 Ω, 2

(a) What is the mean resistance?

(A) 0.235 Ω
(B) 0.247 Ω
(C) 0.251 Ω
(D) 0.259 Ω

The answer is (B).

(b) What is the sample standard deviation?

(A) 0.0003
(B) 0.010
(C) 0.016
(D) 0.24

The answer is (C).

(c) What is the median resistance?

(A) 0.221 Ω
(B) 0.244 Ω
(C) 0.252 Ω
(D) 0.259 Ω

The answer is (B).

(d) What is the sample variance?

(A) 0.00027
(B) 0.0083
(C) 0.0114
(D) 0.0163

The answer is (A).

12 Numerical Analysis

1. Numerical Methods 12-1
2. Finding Roots: Bisection Method 12-1
3. Finding Roots: Newton's Method 12-2
4. Nonlinear Interpolation: Lagrangian Interpolating Polynomial 12-2
5. Nonlinear Interpolation: Newton's Interpolating Polynomial 12-3

Practice Problems 12-4

1. NUMERICAL METHODS

Although the roots of second-degree polynomials are easily found by a variety of methods (by factoring, completing the square, or using the quadratic equation), easy methods of solving cubic and higher-order equations exist only for specialized cases. However, cubic and higher-order equations occur frequently in engineering, and they are difficult to factor. Trial and error solutions, including graphing, are usually satisfactory for finding only the general region in which the root occurs.

Numerical analysis is a general subject that covers, among other things, iterative methods for evaluating roots to equations. The most efficient numerical methods are too complex to present and, in any case, work by hand. However, some of the simpler methods are presented here. Except in critical problems that must be solved in real time, a few extra calculator or computer iterations will make no difference.[1]

2. FINDING ROOTS: BISECTION METHOD

The *bisection method* is an iterative method that "brackets" (also known as "straddles") an interval containing the *root* or *zero* of a particular equation.[2] The size of the interval is halved after each iteration. As the method's name suggests, the best estimate of the root after any iteration is the midpoint of the interval. The maximum error is half the interval length. The procedure continues until the size of the maximum error is "acceptable."[3]

[1]Most advanced hand-held calculators now have "root finder" functions that use numerical methods to iteratively solve equations.

[2]The equation does not have to be a pure polynomial. The bisection method requires only that the equation be defined and determinable at all points in the interval.

[3]The bisection method is not a closed method. Unless the root actually falls on the midpoint of one iteration's interval, the method continues indefinitely. Eventually, the magnitude of the maximum error is small enough not tomatter.

The disadvantages of the bisection method are (a) the slowness in converging to the root, (b) the need to know the interval containing the root before starting, and (c) the inability to determine the existence of or find other real roots in the starting interval.

The bisection method starts with two values of the independent variable, $x = L_0$ and $x = R_0$, which straddle a root. Since the function passes through zero at a root, $f(L_0)$ and $f(R_0)$ will have opposite signs. The following algorithm describes the remainder of the bisection method.

Let n be the iteration number. Then, for $n = 0, 1, 2, \ldots$, perform the following steps until sufficient accuracy is attained.

step 1: Set $m = \frac{1}{2}(L_n + R_n)$.

step 2: Calculate $f(m)$.

step 3: If $f(L_n)f(m) \leq 0$, set $L_{n+1} = L_n$ and $R_{n+1} = m$. Otherwise, set $L_{n+1} = m$ and $R_{n+1} = R_n$.

step 4: $f(x)$ has at least one root in the interval (L_{n+1}, R_{n+1}). The estimated value of that root, x^*, is

$$x^* \approx \tfrac{1}{2}(L_{n+1} + R_{n+1})$$

The maximum error is $\frac{1}{2}(R_{n+1} - L_{n+1})$.

Example 12.1

Use two iterations of the bisection method to find a root of

$$f(x) = x^3 - 2x - 7$$

Solution

The first step is to find L_0 and R_0, which are the values of x that straddle a root and have opposite signs. A table can be made and values of $f(x)$ calculated for random values of x.

x	-2	-1	0	$+1$	$+2$	$+3$
$f(x)$	-11	-6	-7	-8	-3	$+14$

Since $f(x)$ changes sign between $x = 2$ and $x = 3$, $L_0 = 2$ and $R_0 = 3$. First iteration, $n = 0$:

$$m = \tfrac{1}{2}(2 + 3) = 2.5$$

$$f(2.5) = (2.5)^3 - (2)(2.5) - 7 = 3.625$$

Since $f(2.5)$ is positive, a root must exist in the interval (2, 2.5). Therefore, $L_1 = 2$ and $R_1 = 2.5$. At this point, the best estimate of the root is

$$x^* \approx \tfrac{1}{2}(2 + 2.5) = 2.25$$

The maximum error is $\tfrac{1}{2}(2.5 - 2) = 0.25$.

second iteration, $n = 1$:

$$m = \tfrac{1}{2}(2 + 2.5) = 2.25$$
$$f(2.25) = (2.25)^3 - (2)(2.25) - 7 = -0.1094$$

Since $f(2.25)$ is negative, a root must exist in the interval (2.25, 2.5). Therefore, $L_2 = 2.25$ and $R_2 = 2.5$. The best estimate of the root is

$$x^* \approx \tfrac{1}{2}(2.25 + 2.5) = 2.375$$

The maximum error is $\tfrac{1}{2}(2.5 - 2.25) = 0.125$.

3. FINDING ROOTS: NEWTON'S METHOD

Many other methods have been developed to overcome one or more of the disadvantages of the bisection method. These methods have their own disadvantages.[4]

Newton's method is a particular form of *fixed-point iteration*. In this sense, "fixed point" is often used as a synonym for "root" or "zero." However, fixed-point iterations get their name from functions with the characteristic property $x = g(x)$ such that the limit of $g(x)$ is the fixed point (i.e., is the root).

All fixed-point techniques require a starting point. Preferably, the starting point will be close to the actual root.[5] And, while Newton's method converges quickly, it requires the function to be continuously differentiable.

Newton's method algorithm is simple. At each iteration ($n = 0$, 1, 2, etc.), Eq. 12.1 estimates the root. The maximum error is determined by looking at how much the estimate changes after each iteration. If the change between the previous and current estimates (representing the magnitude of error in the estimate) is too large, the current estimate is used as the independent variable for the subsequent iteration.[6]

$$x_{n+1} = g(x_n) = x_n - \frac{f(x_n)}{f'(x_n)} \qquad 12.1$$

[4]The *regula falsi (false position) method* converges faster than the bisection method but is unable to specify a small interval containing the root. The *secant method* is prone to round-off errors and gives no indication of the remaining distance to the root.

[5]Theoretically, the only penalty for choosing a starting point too far away from the root will be a slower convergence to the root.

[6]Actually, the theory defining the maximum error is more definite than this. For example, for a large enough value of n, the error decreases approximately linearly. Therefore, the consecutive values of x_n converge linearly to the root as well.

Example 12.2

Solve Ex. 12.1 using two iterations of Newton's method. Use $x_0 = 2$.

Solution

The function and its first derivative are

$$f(x) = x^3 - 2x - 7$$
$$f'(x) = 3x^2 - 2$$

first iteration, $n = 0$:

$$x_0 = 2$$
$$f(x_0) = f(2) = (2)^3 - (2)(2) - 7 = -3$$
$$f'(x_0) = f'(2) = (3)(2)^2 - 2 = 10$$
$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)} = 2 - \frac{-3}{10} = 2.3$$

second iteration, $n = 1$:

$$x_1 = 2.3$$
$$f(x_1) = (2.3)^3 - (2)(2.3) - 7 = 0.567$$
$$f'(x_1) = (3)(2.3)^2 - 2 = 13.87$$
$$x_2 = x_1 - \frac{f(x_1)}{f'(x_1)} = 2.3 - \frac{0.567}{13.87} = 2.259$$

4. NONLINEAR INTERPOLATION: LAGRANGIAN INTERPOLATING POLYNOMIAL

Interpolating between two points of known data is common in engineering. Primarily due to its simplicity and speed, straight-line interpolation is used most often. Even if more than two points on the curve are explicitly known, they are not used. Since straight-line interpolation ignores all but two of the points on the curve, it ignores the effects of curvature.

A more powerful technique that accounts for the curvature is the *Lagrangian interpolating polynomial*. This method uses an nth degree parabola (polynomial) as the interpolating curve.[7] This method requires that $f(x)$ be continuous and real-valued on the interval $[x_0, x_n]$ and that $n + 1$ values of $f(x)$ are known corresponding to $x_0, x_1, x_2, \ldots, x_n$.

The procedure for calculating $f(x)$ at some intermediate point x^* starts by calculating the Lagrangian interpolating polynomial for each known point.

$$L_k(x^*) = \prod_{\substack{i=0 \\ i \neq k}}^{n} \frac{x^* - x_i}{x_k - x_i} \qquad 12.2$$

[7]The Lagrangian interpolating polynomial reduces to straight-line interpolation if only two points are used.

The value of $f(x)$ at x^* is calculated from Eq. 12.3.

$$f(x^*) = \sum_{k=0}^{n} f(x_k) L_k(x^*) \qquad 12.3$$

The Lagrangian interpolating polynomial has two primary disadvantages. The first is that a large number of additions and multiplications are needed.[8] The second is that the method does not indicate how many interpolating points should be (or should have been) used. Other interpolating methods have been developed that overcome these disadvantages.[9]

Example 12.3

A real-valued function has the following values.

$$f(1) = 3.5709$$
$$f(4) = 3.5727$$
$$f(6) = 3.5751$$

Use the Lagrangian interpolating polynomial to determine the value of the function at 3.5.

Solution

The procedure for applying Eq. 12.2, the Lagrangian interpolating polynomial, is illustrated in tabular form. Notice that the term corresponding to $i = k$ is omitted from the product.

$$\begin{aligned} & & i=0 & & i=1 & & i=2 \\ k=0\text{:}\ L_0(3.5) &= \left(\frac{3.5-1}{1-1}\right)\left(\frac{3.5-4}{1-4}\right)\left(\frac{3.5-6}{1-6}\right) \\ &= 0.08333 \\ k=1\text{:}\ L_1(3.5) &= \left(\frac{3.5-1}{4-1}\right)\left(\frac{3.5-4}{4-4}\right)\left(\frac{3.5-6}{4-6}\right) \\ &= 1.04167 \\ k=2\text{:}\ L_2(3.5) &= \left(\frac{3.5-1}{6-1}\right)\left(\frac{3.5-4}{6-4}\right)\left(\frac{3.5-6}{6-6}\right) \\ &= -0.12500 \end{aligned}$$

Equation 12.3 is used to calculate the estimate.

$$\begin{aligned} f(3.5) &= (3.5709)(0.08333) + (3.5727)(1.04167) \\ &\quad + (3.5751)(-0.12500) \\ &= 3.57225 \end{aligned}$$

[8] As with the numerical methods for finding roots previously discussed, the number of calculations probably will not be an issue if the work is performed by a calculator or computer.

[9] Other common methods for performing interpolation include the *Newton form* and *divided difference table*.

5. NONLINEAR INTERPOLATION: NEWTON'S INTERPOLATING POLYNOMIAL

Newton's form of the interpolating polynomial is more efficient than the Lagrangian method of interpolating between known points.[10] Given $n+1$ known points for $f(x)$, the *Newton form of the interpolating polynomial* is

$$f(x^*) = \sum_{i=0}^{n} \left(f[x_0, x_1, \ldots, x_i] \prod_{j=0}^{i-1} (x^* - x_j) \right) \qquad 12.4$$

$f[x_0, x_1, \ldots, x_i]$ is known as the ith *divided difference*.

$$f[x_0, x_1, \ldots, x_i] = \sum_{k=0}^{i} \left(\frac{f(x_k)}{\begin{array}{c}(x_k - x_0)\cdots(x_k - x_{k-1}) \\ \times (x_k - x_{k+1})\cdots(x_k - x_i)\end{array}} \right) \qquad 12.5$$

It is necessary to define the following two terms.

$$f[x_0] = f(x_0) \qquad 12.6$$

$$\prod (x^* - x_j) = 1 \qquad [i = 0] \qquad 12.7$$

Example 12.4

Repeat Ex. 12.3 using Newton's form of the interpolating polynomial.

Solution

Since there are $n + 1 = 3$ data points, $n = 2$. Evaluate the terms for $i = 0$ to 2.

$i = 0$:

$$f[x_0] \prod_{j=0}^{-1} (x^* - x_j) = f(x_0)(1) = f(x_0)$$

$i = 1$:

$$f[x_0, x_1] \prod_{j=0}^{0} (x^* - x_j) = f[x_0, x_1](x^* - x_0)$$

$$f[x_0, x_1] = \frac{f(x_0)}{x_0 - x_1} + \frac{f(x_1)}{x_1 - x_0}$$

$i = 2$:

$$f[x_0, x_1, x_0] \prod_{j=0}^{1} (x^* - x_j) = f[x_0, x_1, x_0](x^* - x_0) \times (x^* - x_1)$$

$$f[x_0, x_1, x_2] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)}$$

[10] In this case, "efficiency" relates to the ease in adding new known points without having to repeat all previous calculations.

Substitute known values.

$$\begin{aligned} f(3.5) &= 3.5709 + \left(\frac{3.5709}{1-4} + \frac{3.5727}{4-1}\right)(3.5-1) \\ &\quad + \left[\frac{3.5709}{(1-4)(1-6)} + \frac{3.5727}{(4-1)(4-6)} \right. \\ &\quad \left. + \frac{3.5751}{(6-1)(6-4)}\right] \\ &\quad \times (3.5-1)(3.5-4) \\ &= 3.57225 \end{aligned}$$

This answer is the same as that determined in Ex. 12.3.

PRACTICE PROBLEMS

1. A function is given as $y = 3x^{0.93} + 4.2$. What is the percent error if the value of y at $x = 2.7$ is found by using straight-line interpolation between $x = 2$ and $x = 3$?

(A) 0.06%
(B) 0.18%
(C) 2.5%
(D) 5.4%

The answer is (A).

2. Given the following data points, find y by straight-line interpolation for $x = 2.75$.

x	y
1	4
2	6
3	2
4	−14

(A) 2.1
(B) 2.4
(C) 2.7
(D) 3.0

The answer is (D).

3. Using the bisection method, find all of the roots of $f(x) = 0$ to the nearest 0.000005.

$$f(x) = x^3 + 2x^2 + 8x - 2$$

Answers: $0.234375; -1.117189 \pm i2.697327$

1. ENERGY OF A MASS

The *energy* of a mass represents the capacity of the mass to do work. Such energy can be stored and released. There are many forms that it can take, including mechanical, thermal, electrical, and magnetic energies. Energy is a positive, scalar quantity (although the change in energy can be either positive or negative).

The total energy of a body can be calculated from its mass, m, and its *specific energy* (i.e., the energy per unit mass).[1]

$$E = m \times \text{specific energy} \qquad 13.1$$

Typical units of mechanical energy are foot-pounds and joules. (A joule is equivalent to the units of N·m and kg·m^2/s^2.) In traditional English-unit countries, the *British thermal unit* (Btu) is used for thermal energy, whereas the kilocalorie (kcal) is still used in some applications in SI countries. *Joule's constant* or the *Joule equivalent* (778.26 ft-lbf/Btu, usually shortened to 778, three significant digits) is used to convert between English mechanical and thermal energy units.

$$\text{energy in Btu} = \frac{\text{energy in ft-lbf}}{J} \qquad 13.2$$

Two other units of large amounts of energy are the therm and the quad. A *therm* is 10^5 Btu (1.055×10^8 J). A *quad* is equal to a quadrillion (10^{15}) Btu. This is 1.055×10^{18} J, roughly the energy contained in 200 million barrels of oil.

[1]The use of symbols E and U for energy is not consistent in the engineering field.

2. LAW OF CONSERVATION OF ENERGY

The *law of conservation of energy* says that energy cannot be created or destroyed. However, energy can be converted into different forms. Therefore, the sum of all energy forms is constant.

$$\sum E = \text{constant} \qquad 13.3$$

3. WORK

Work, W, is the act of changing the energy of a particle, body, or system. For a mechanical system, *external work* is work done by an external force, whereas *internal work* is done by an internal force. Work is a signed, scalar quantity. Typical units are inch-pounds, foot-pounds, and joules. Mechanical work is seldom expressed in British thermal units or kilocalories.

For a mechanical system, work is positive when a force acts in the direction of motion and helps a body move from one location to another. Work is negative when a force acts to oppose motion. (Friction, for example, always opposes the direction of motion and can do only negative work.) The work done on a body by more than one force can be found by superposition.

From a thermodynamic standpoint, work is positive if a particle or body does work on its surroundings. Work is negative if the surroundings do work on the object. (Thus, blowing up a balloon represents negative work to the balloon.) Although this may be a difficult concept, it is consistent with the conservation of energy, since the sum of negative work and the positive energy increase is zero (i.e., no net energy change in the system).[2]

The work performed by a variable force or torque is calculated from the dot products of Eqs. 13.4 and 13.5,

$$W_{\text{variable force}} = \int \mathbf{F} \cdot d\mathbf{s} \quad \text{[linear systems]} \qquad 13.4$$

$$W_{\text{variable torque}} = \int \mathbf{T} \cdot d\boldsymbol{\theta} \quad \text{[rotational systems]} \qquad 13.5$$

The work done by a force or torque of constant magnitude is

$$W_{\text{constant force}} = \mathbf{F} \cdot \mathbf{s} = Fs \cos\phi \quad \text{[linear systems]} \qquad 13.6$$

$$W_{\text{constant torque}} = \mathbf{T} \cdot \boldsymbol{\theta} = Fr\theta \cos\phi \quad \text{[rotational systems]} \qquad 13.7$$

The nonvector forms, Eqs. 13.6 and 13.7, illustrate that only the component of force or torque in the direction of motion contributes to work.

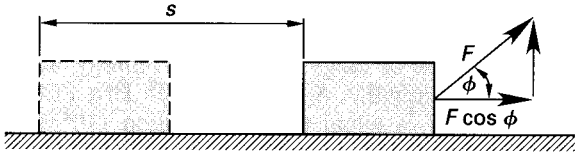

Figure 13.1 *Work of a Constant Force*

[2]This is just a partial statement of the *first law of thermodynamics*.

Common applications of the work done by a constant force are frictional work and gravitational work. The work to move an object a distance s against a frictional force of F_f is

$$W_{\text{friction}} = F_f s \qquad 13.8$$

The work done by gravity when a mass m changes in elevation from h_1 to h_2 is

$$W_{\text{gravity}} = mg(h_2 - h_1) \quad \text{[SI]} \qquad 13.9(a)$$

$$W_{\text{gravity}} = \left(\frac{mg}{g_c}\right)(h_2 - h_1) \quad \text{[U.S.]} \qquad 13.9(b)$$

The work done by or on a *linear spring* whose length or deflection changes from δ_1 to δ_2 is given by Eq. 13.10.[3] It does not make any difference whether the spring is a compression spring or an extension spring.

$$W_{\text{spring}} = \tfrac{1}{2}k\left(\delta_2^2 - \delta_1^2\right) \qquad 13.10$$

Example 13.1

A lawn mower engine is started by pulling a cord wrapped around a sheave. The sheave radius is 8.0 cm. The cord is wrapped around the sheave two times. If a constant tension of 90 N is maintained in the cord during starting, what work is done?

Solution

The starting torque on the engine is

$$T = Fr = (90\text{ N})\left(\frac{8\text{ cm}}{100\ \frac{\text{cm}}{\text{m}}}\right)$$
$$= 7.2\text{ N·m}$$

The cord wraps around the sheave $(2)(2\pi) = 12.6$ rad. From Eq. 13.7, the work done by a constant torque is

$$W = T\theta = (7.2\text{ N·m})(12.6\text{ rad})$$
$$= 90.7\text{ J}$$

Example 13.2

A 200 lbm crate is pushed 25 ft at constant velocity across a warehouse floor. There is a frictional force of 60 lbf between the crate and floor. What work is done by the frictional force on the crate?

Solution

From Eq. 13.8,

$$W_{\text{friction}} = F_f s = (60\text{ lbf})(25\text{ ft})$$
$$= 1500\text{ ft-lbf}$$

[3]A *linear spring* is one for which the linear relationship $F = kx$ is valid.

4. POTENTIAL ENERGY OF A MASS

Potential energy (gravitational energy) is a form of mechanical energy possessed by a body due to its relative position in a gravitational field. Potential energy is lost when the elevation of a body decreases. The lost potential energy usually is converted to kinetic energy or heat.

$$E_{\text{potential}} = mgh \quad \text{[SI]} \qquad 13.11(a)$$

$$E_{\text{potential}} = \frac{mgh}{g_c} \quad \text{[U.S.]} \qquad 13.11(b)$$

In the absence of friction and other nonconservative forces, the change in potential energy of a body is equal to the work required to change the elevation of the body.

$$W = \Delta E_{\text{potential}} \qquad 13.12$$

5. KINETIC ENERGY OF A MASS

Kinetic energy is a form of mechanical energy associated with a moving or rotating body. The kinetic energy of a body moving with instantaneous linear velocity v is

$$E_{\text{kinetic}} = \tfrac{1}{2}mv^2 \quad \text{[SI]} \qquad 13.13(a)$$

$$E_{\text{kinetic}} = \frac{mv^2}{2g_c} \quad \text{[U.S.]} \qquad 13.13(b)$$

According to the *work-energy principle* (see Sec. 13.9), the kinetic energy is equal to the work necessary to initially accelerate a stationary body, or to bring a moving body to rest.

$$W = \Delta E_{\text{kinetic}} \qquad 13.14$$

A body can also have rotational kinetic energy.

$$E_{\text{rotational}} = \tfrac{1}{2}I\omega^2 \quad \text{[SI]} \qquad 13.15(a)$$

$$E_{\text{rotational}} = \frac{I\omega^2}{2g_c} \quad \text{[U.S.]} \qquad 13.15(b)$$

Example 13.3

A solid disk flywheel ($I = 200\ \text{kg·m}^2$) is rotating with a speed of 900 rpm. What is its rotational kinetic energy?

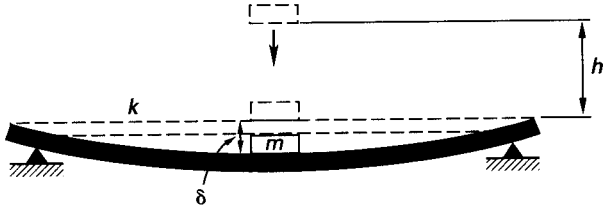
Solution

The angular rotational velocity is

$$\omega = \frac{(900\ \text{rpm})\left(2\pi\ \frac{\text{rad}}{\text{rev}}\right)}{60\ \frac{\text{s}}{\text{min}}} = 94.25\ \text{rad/s}$$

From Eq. 13.15, the rotational kinetic energy is

$$E = \tfrac{1}{2}I\omega^2 = \left(\tfrac{1}{2}\right)(200\ \text{kg·m}^2)\left(94.25\ \frac{\text{rad}}{\text{s}}\right)^2$$
$$= 888 \times 10^3\ \text{J} \quad (888\ \text{kJ})$$



6. SPRING ENERGY

A spring is an energy storage device, since the spring has the ability to perform work. In a perfect spring, the amount of energy stored is equal to the work required to compress the spring initially. The stored spring energy does not depend on the mass of the spring. Given a spring with spring constant (stiffness) k, the *spring energy* is

$$E_{\text{spring}} = \tfrac{1}{2}k\delta^2 \qquad 13.16$$

Example 13.4

A body of mass m falls from height h onto a massless, simply supported beam. The mass adheres to the beam. If the beam has a lateral stiffness k, what will be the deflection, δ, of the beam?

Solution

The initial energy of the system consists of only the potential energy of the body. Using consistent units, the change in potential energy is

$$E = mg(h + \delta) \qquad \text{[consistent units]}$$

All of this energy is stored in the spring. Therefore,

$$\tfrac{1}{2}k\delta^2 = mg(h + \delta)$$

Solving for the deflection,

$$\delta = \frac{mg \pm \sqrt{mg(2hk + mg)}}{k}$$

7. PRESSURE ENERGY OF A MASS

Since work is done in increasing the pressure of a system (i.e., it takes work to blow up a balloon), mechanical energy can be stored in pressure form. This is known as *pressure energy, static energy, flow energy, flow work,* and *p-V work (energy).* For a system of pressurized mass m, the pressure energy is

$$E_{\text{flow}} = \frac{mp}{\rho} = mpv \qquad 13.17$$

8. INTERNAL ENERGY OF A MASS

The total internal energy, usually given the symbol U, of a body increases when the body's temperature increases.[4] In the absence of any work done on or by the body, the change in internal energy is equal to the heat flow, Q, into the body. Q is positive if the heat flow is into the body and negative otherwise.

$$U_2 - U_1 = Q \qquad 13.18$$

The property of internal energy is encountered primarily in thermodynamics problems. Typical units are British thermal units, joules, and kilocalories.

An increase in internal energy is needed to cause a rise in temperature. Different substances differ in the quantity of heat needed to produce a given temperature increase. The ratio of heat, Q, required to change the temperature of a mass, m, by an amount ΔT is called the *specific heat* (*heat capacity*) of the substance, c.

Because specific heats of solids and liquids are slightly temperature dependent, the mean specific heats are used when evaluating processes covering a large temperature range.

$$Q = mc\,\Delta T \qquad 13.19$$

$$c = \frac{Q}{m\Delta T} \qquad 13.20$$

The lowercase c implies that the units are Btu/lbm-°F or J/kg·°C. Typical values of specific heat are given in Table 13.1. The *molar specific heat*, designated by the symbol C, has units of Btu/lbmol-°F or J/kmol·°C.

$$C = (\text{MW}) \times c \qquad 13.21$$

For gases, the specific heat depends on the type of process during which the heat exchange occurs. Specific heats for constant-volume and constant-pressure processes are designated by c_v and c_p, respectively.

$$Q = mc_v\Delta T \quad \text{[constant-volume process]} \qquad 13.22$$

$$Q = mc_p\Delta T \quad \text{[constant-pressure process]} \qquad 13.23$$

Approximate values of c_p and c_v for solids and liquids are essentially the same. However, the designation c_p is often encountered for solids and liquids.

Table 13.1 *Approximate Specific Heats of Selected Liquids and Solids*[a]

substance	c_p Btu/lbm-°F	c_p kJ/kg·K
aluminum, pure	0.23	0.96
aluminum, 2024-T4	0.2	0.84
ammonia	1.16	4.86
asbestos	0.20	0.84
benzene	0.41	1.72
brass, red	0.093	0.39
bronze	0.082	0.34
concrete	0.21	0.88
copper, pure	0.094	0.39
Freon-12	0.24	1.00
gasoline	0.53	2.20
glass	0.18	0.75
gold, pure	0.031	0.13
ice	0.49	2.05
iron, pure	0.11	0.46
iron, cast (4% C)	0.10	0.42
lead, pure	0.031	0.13
magnesium, pure	0.24	1.00
mercury	0.033	0.14
oil, light hydrocarbon	0.5	2.09
silver, pure	0.06	0.25
steel, 1010	0.10	0.42
steel, stainless 301	0.11	0.46

titanium, pure	0.13	0.54
tungsten, pure	0.032	0.13
water	1.0	4.19
wood (typical)	0.6	2.50
zinc, pure	0.088	0.37

(Multiply Btu/lbm-°F by 4.1868 to obtain kJ/kg·K.)
[a]Values in cal/g·°C are the same as Btu/lbm-°F.

9. WORK-ENERGY PRINCIPLE

Since energy can neither be created nor destroyed, external work performed on a conservative system goes into changing the system's total energy. This is known as the *work-energy principle* (or *principle of work and energy*).

$$W = \Delta E = E_2 - E_1 \qquad 13.24$$

Generally, the term *work-energy principle* is limited to use with mechanical energy problems (i.e., conversion of work into kinetic or potential energies). When energy is limited to kinetic energy, the work-energy principle is a direct consequence of Newton's second law but is valid for only inertial reference systems.

By directly relating forces, displacements, and velocities, the work-energy principle introduces some simplifications into many mechanical problems.

- It is not necessary to calculate or know the acceleration of a body to calculate the work performed on it.
- Forces that do not contribute to work (e.g., are normal to the direction of motion) are irrelevant.
- Only scalar quantities are involved.
- It is not necessary to individually analyze the particles or component parts in a complex system.

[4]The *thermal energy*, represented by the body's enthalpy, is the sum of internal and pressure energies.

Example 13.5

A 4000 kg elevator starts from rest, accelerates uniformly to a constant speed of 2.0 m/s, and then decelerates uniformly to a stop 20 m above its initial position. Neglecting friction and other losses, what work was done on the elevator?

Solution

By the work-energy principle, the work done on the elevator is equal to the change in the elevator's energy. Since the initial and final kinetic energies are zero, the only mechanical energy change is the potential energy change.

Taking the initial elevation of the elevator as the reference (i.e., $h_1 = 0$),

$$W = E_{2,\text{potential}} - E_{1,\text{potential}} = mg(h_2 - h_1)$$

$$= (4000\text{ kg})\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(20\text{ m}) = 785 \times 10^3\text{ J (785 kJ)}$$

10. CONVERSION BETWEEN ENERGY FORMS

Conversion of one form of energy into another does not violate the conservation of energy law. However, most problems involving conversion of energy are really just special cases of the work-energy principle. For example, consider a falling body that is acted upon by a gravitational force. The conversion of potential energy into kinetic energy can be interpreted as equating the work done by the constant gravitational force to the change in kinetic energy.

In general terms, *Joule's law* states that one energy form can be converted without loss into another. There are two specific formulations of *Joule's Law*. As related to electricity, $P = I^2R = V^2/R$ is the common formulation of Joule's law. As related to thermodynamics and ideal gases, Joule's law states that "the change in internal energy of an ideal gas is a function of the temperature change, not of the volume." This latter form can also be stated more formally as "at constant temperature, the internal energy of a gas approaches a finite value that is independent of the volume as the pressure goes to zero."

Example 13.6

A 2.0 lbm projectile is launched straight up with an initial velocity of 700 ft/sec. Neglecting air friction, calculate the (a) kinetic energy immediately after launch, (b) kinetic energy at maximum height, (c) potential energy at maximum height, (d) total energy at an elevation where the velocity has dropped to 300 ft/sec, and (e) maximum height attained.

Solution

(a) From Eq. 13.13, the kinetic energy is

$$E_{\text{kinetic}} = \frac{mv^2}{2g_c} = \frac{(2\text{ lbm})\left(700\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{lbm-ft}}{\text{sec}^2\text{-lbf}}\right)}$$

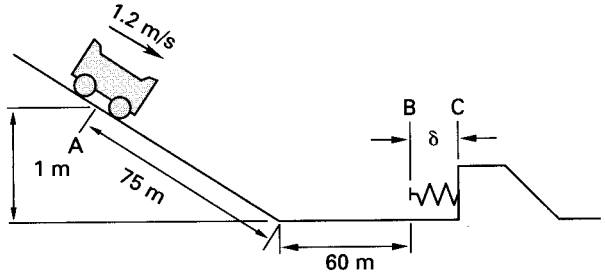
$$= 15{,}217\text{ ft-lbf}$$

(b) The velocity is zero at the maximum height. Therefore, the kinetic energy is zero.

(c) At the maximum height, all of the kinetic energy has been converted into potential energy. Therefore, the potential energy is 15,217 ft-lbf.

(d) Although some of the kinetic energy has been transformed into potential energy, the total energy is still 15,217 ft-lbf.

(e) Since all of the kinetic energy has been converted into potential energy, the maximum height can be found from Eq. 13.11.



$$E_{\text{potential}} = \frac{mgh}{g_c}$$

$$15{,}217\text{ ft-lbf} = \frac{(2\text{ lbm})\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)(h)}{32.2\ \frac{\text{lbm-ft}}{\text{sec}^2\text{-lbf}}}$$

$$h = 7609\text{ ft}$$

Example 13.7

A 4500 kg ore car rolls down an incline and passes point A traveling at 1.2 m/s. The ore car is stopped by a spring bumper that compresses 0.6 m. A constant friction force of 220 N acts on the ore car at all times. What spring constant is required?

Solution

The car's total energy at point A is the sum of the kinetic and potential energies.

$$E_{\text{total,A}} = E_{\text{kinetic}} + E_{\text{potential}}$$

$$= \tfrac{1}{2}mv^2 + mgh$$

$$= \left(\tfrac{1}{2}\right)(4500\text{ kg})\left(1.2\ \frac{\text{m}}{\text{s}}\right)^2 + (4500\text{ kg})\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(1\text{ m})$$

$$= 47\,385\text{ J}$$

At point B, the potential energy has been converted into additional kinetic energy. However, except for friction, the total energy is the same as at point A. Since the frictional force does negative work, the total energy remaining at point B is

$$\begin{aligned} E_{\text{total,B}} &= E_{\text{total,A}} - W_{\text{friction}} \\ &= 47\,385\text{ J} - (220\text{ N})(75\text{ m} + 60\text{ m}) \\ &= 17\,685\text{ J} \end{aligned}$$

At point C, the maximum compression point, the remaining energy has gone into compressing the spring a distance $\delta = 0.6$ m and performing a small amount of frictional work.

$$\begin{aligned} E_{\text{total,B}} &= E_{\text{total,C}} = W_{\text{spring}} + W_{\text{friction}} \\ &= \tfrac{1}{2}k\delta^2 + F_f\delta \\ 17\,685\text{ J} &= \left(\tfrac{1}{2}\right)(k)(0.6\text{ m})^2 + (220\text{ N})(0.6\text{ m}) \end{aligned}$$

The spring constant can be determined directly.

$$k = 97\,520\text{ N/m} \quad (97.5\text{ kN/m})$$

11. POWER

Power is the amount of work done per unit time. It is a scalar quantity. (Although power is calculated from two vectors, the vector dot-product operation is seldom needed.)

$$P = \frac{W}{\Delta t} \qquad 13.25$$

For a body acted upon by a force or torque, the instantaneous power can be calculated from the velocity.

$$P = F\text{v} \quad \text{[linear systems]} \qquad 13.26$$

$$P = T\omega \quad \text{[rotational systems]} \qquad 13.27$$

Typical basic units of power are ft-lbf/sec and watts (J/s), although *horsepower* is widely used. Table 13.2 can be used to convert units of power.

Table 13.2 *Useful Power Conversion Formulas*

1 hp	= 550 ft-lbf/sec
	= 33,000 ft-lbf/min
	= 0.7457 kW
	= 0.7068 Btu/sec
1 kW	= 737.6 ft-lbf/sec
	= 44,250 ft-lbf/min
	= 1.341 hp
	= 0.9483 Btu/sec
1 Btu/sec	= 778.26 ft-lbf/sec
	= 46,680 ft-lbf/min
	= 1.415 hp

Example 13.8

When traveling at 100 km/h, a car supplies a constant horizontal force of 50 N to the hitch of a trailer. What tractive power (in horsepower) is required for the trailer alone?

Solution

From Eq. 13.26, the power being generated is

$$\begin{aligned} P = F\text{v} &= \frac{(50\text{ N})\left(100\,\frac{\text{km}}{\text{h}}\right)\left(1000\,\frac{\text{m}}{\text{km}}\right)}{\left(60\,\frac{\text{s}}{\text{min}}\right)\left(60\,\frac{\text{min}}{\text{h}}\right)\left(1000\,\frac{\text{W}}{\text{kW}}\right)} \\ &= 1.389\text{ kW} \end{aligned}$$

Using a conversion from Table 13.2, the horsepower is

$$\begin{aligned} P &= \left(1.341\,\frac{\text{hp}}{\text{kW}}\right)(1.389\text{ kW}) \\ &= 1.86\text{ hp} \end{aligned}$$

12. EFFICIENCY

For energy-using systems (such as cars, electrical motors, elevators, etc.), the *energy-use efficiency*, η, of a system is the ratio of an ideal property to an actual property. The property used is commonly work, power, or, for thermodynamic problems, heat. When the rate of work is constant, either work or power can be used to calculate the efficiency. Otherwise, power should be used. Except in rare instances, the numerator and denominator of the ratio must have the same units.[5]

$$\eta = \frac{P_{\text{ideal}}}{P_{\text{actual}}} \qquad [P_{\text{actual}} \geq P_{\text{ideal}}] \qquad 13.28$$

For energy-producing systems (such as electrical generators, prime movers, and hydroelectric plants), the *energy-production efficiency* is

$$\eta = \frac{P_{\text{actual}}}{P_{\text{ideal}}} \qquad [P_{\text{ideal}} \geq P_{\text{actual}}] \qquad 13.29$$

The efficiency of an *ideal machine* is 1.0 (100%). However, all *real machines* have efficiencies of less than 1.0.

[5]The *energy-efficiency ratio* used to evaluate refrigerators, air conditioners, and heat pumps, for example, has units of Btu per watt-hour (Btu/W-hr).

1. CHARACTERISTICS OF A FLUID

Liquids and gases can both be categorized as fluids, although this chapter is primarily concerned with incompressible liquids. There are certain characteristics shared by all fluids, and these characteristics can be used, if necessary, to distinguish between liquids and gases.[1]

- *Compressibility*: Liquids are only slightly compressible and are assumed to be incompressible for most purposes. Gases are highly compressible.
- *Shear resistance*: Liquids and gases cannot support shear, and they deform continuously to minimize applied shear forces.
- *Shape and volume*: As a consequence of their inability to support shear forces, liquids and gases take on the shapes of their containers. Only liquids have free surfaces. Liquids have fixed volumes, regardless of their container volumes, and these volumes are not significantly affected by temperature and pressure. Gases take on the volumes

[1]The differences between liquids and gases become smaller as temperature and pressure are increased. Gas and liquid properties become the same at the critical temperature and pressure.

of their containers. If allowed to do so, gas volumes will change as temperature and pressure are varied.

- *Resistance to motion*: Due to viscosity, liquids resist instantaneous changes in velocity, but the resistance stops when liquid motion stops. Gases have very low viscosities.
- *Molecular spacing*: Molecules in liquids are relatively close together and are held together with strong forces of attraction. Liquid molecules have low kinetic energy. The distance each liquid molecule travels between collisions is small. In gases, the molecules are relatively far apart and the attractive forces are weak. Kinetic energy of the molecules is high. Gas molecules travel larger distances between collisions.
- *Pressure*: The pressure at a point in a fluid is the same in all directions. Pressure exerted by a fluid on a solid surface (e.g., container wall) is always normal to that surface.

2. TYPES OF FLUIDS

For computational convenience, fluids are generally divided into two categories: ideal fluids and real fluids. *Ideal fluids* are assumed to have no viscosity (and hence, no resistance to shear), be incompressible, and have uniform velocity distributions when flowing. In an ideal fluid, there is no friction between moving layers of fluid, and there are no eddy currents or turbulence.

Real fluids exhibit finite viscosities and non-uniform velocity distributions, are compressible, and experience friction and turbulence in flow. Real fluids are further divided into *Newtonian fluids* and *non-Newtonian fluids*, depending on their viscous behavior. The differences between Newtonian and the various types of non-Newtonian fluids are described in Sec. 9.

For convenience, most fluid problems assume real fluids with Newtonian characteristics. This is an appropriate assumption for water, air, gases, steam, and other simple fluids (alcohol, gasoline, acid solutions, etc.). However, slurries, pastes, gels, suspensions, and polymer/electrolyte solutions may not behave according to simple fluid relationships.

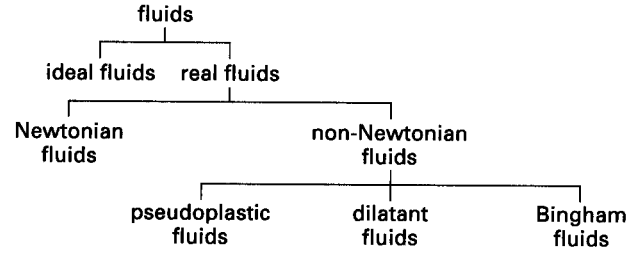

Figure 14.1 *Types of Fluids*

3. FLUID PRESSURE AND VACUUM

In the English system, fluid pressure is measured in pounds per square inch (lbf/in^2 or psi) and pounds per square foot (lbf/ft^2 or psf), although tons (2000 pounds) per square foot (tsf) are occasionally used. In SI units, pressure is measured in pascals (Pa). Because a pascal is very small, kilopascals (kPa) are usually used. Other units of pressure are bars; millibars; atmospheres; inches and feet of water; millimeters, centimeters, and inches of mercury; and torrs.

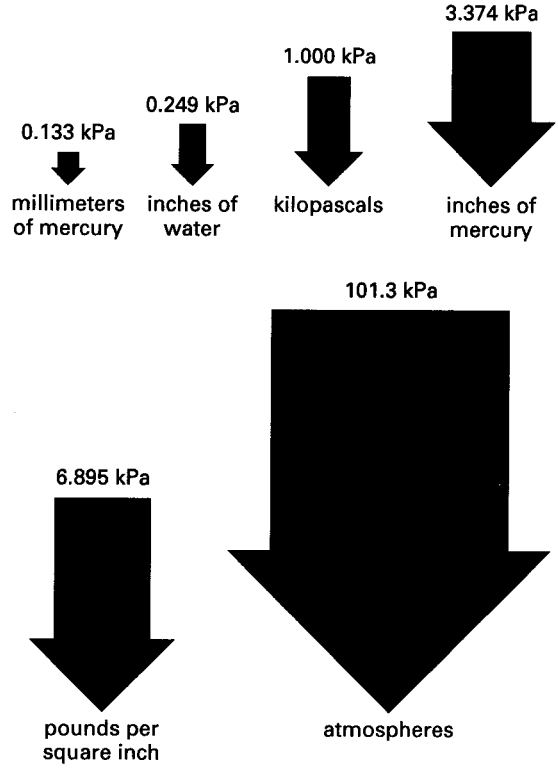

Figure 14.2 *Relative Sizes of Pressure Units*

Fluid pressures are measured with respect to two pressure references: zero pressure and atmospheric pressure. Pressures measured with respect to a true zero pressure reference are known as *absolute pressures*. Pressures measured with respect to atmospheric pressure are known as *gage pressures*.[2] Most pressure gauges read the excess of the test pressure over atmospheric pressure (i.e., the gage pressure). To distinguish between these two pressure measurements, the letters "a" and "g" are traditionally added to the the unit symbols in the English unit system (e.g., 14.7 psia and 4015 psfg). For SI units, the actual words "gauge" and "absolute" can be added to the measurement (e.g., 25.1 kPa absolute). Alternatively, the pressure is assumed to be absolute unless the "g" is used (e.g., 15 Pag).

[2]The spelling *gage* persists even though pressures are measured with *gauges*. In some countries, the term *meter pressure* is used instead of gage pressure.

Absolute and gage pressures are related by Eq. 14.1. It should be mentioned that $p_{\text{atmospheric}}$ in Eq. 14.1 is the actual atmospheric pressure existing when the gage measurement is taken. It is not standard atmospheric pressure, unless that pressure is implicitly or explicitly applicable. Also, since a barometer measures atmospheric pressure, *barometric pressure* is synonymous with atmospheric pressure. Table 14.1 lists standard atmospheric pressure in various units.

$$p_{\text{absolute}} = p_{\text{gage}} + p_{\text{atmospheric}} \qquad 14.1$$

Table 14.1 *Standard Atmospheric Pressure*

1.000 atm	(atmosphere)
14.696 psia	(pounds per square inch absolute)
2116.2 psfa	(pounds per square foot absolute)
407.1 in wg	(inches of water, inches water gage)
33.93 ft wg	(feet of water, feet water gage)
29.921 in Hg	(inches of mercury)
760.0 mm Hg	(millimeters of mercury)
760.0 torr	
1.013 bars	
1013 millibars	
1.013×10^5 Pa	(pascals)
101.3 kPa	(kilopascals)

A *vacuum* measurement is implicitly a pressure below atmospheric (i.e., a negative gage pressure). It must be assumed that any measured quantity given as a vacuum is a quantity to be subtracted from the atmospheric pressure. Thus, when a condenser is operating with a vacuum of 4.0 in Hg (4 in of mercury), the absolute pressure is approximately 29.92 in Hg − 4.0 in Hg = 25.92 in Hg. Vacuums are always stated as positive numbers.

$$p_{\text{absolute}} = p_{\text{atmospheric}} - p_{\text{vacuum}} \qquad 14.2$$

4. DENSITY

The *density*, ρ, of a fluid is its mass per unit volume.[3] In SI units, density is measured in kg/m^3. In a consistent English system, density is measured in slugs/ft^3, even though fluid density is traditionally reported in lbm/ft^3.

$$\rho = \text{ fluid density} \qquad 14.3$$

The density of a fluid in a liquid form is usually given, known in advance, or easily obtained from tables in any one of a number of sources. Most English fluid data are reported on a per pound basis, and the data included in this book follow that tradition. To make the conversion from pounds to slugs, divide by g_c as an implied step whenever using pound-basis fluid data.

$$\rho_{\text{slugs}} = \frac{\rho_{\text{lbm}}}{g_c} \qquad 14.4$$

The density of an ideal gas can be found from the specific gas constant and the ideal gas law.

$$\rho = \frac{p}{RT} \qquad 14.5$$

Table 14.2 *Approximate Room-Temperature Densities of Common Fluids*

fluid	lbm/ft^3	kg/m^3
air (STP)	0.0807	1.29
air (70°F, 1 atm)	0.075	1.20
alcohol	49.3	790
ammonia	38	602
gasoline	44.9	720
glycerin	78.8	1260
mercury	848	13 600
water	62.4	1000

(Multiply lbm/ft^3 by 16.01 to obtain kg/m^3.)

Example 14.1

The density of water is typically taken as 62.4 lbm/ft^3 for engineering problems where greater accuracy is not required. What is the value in (a) slugs/ft^3 and (b) kg/m^3?

Solution

(a) Equation 14.4 can be used to calculate the slug-density of water.

$$\rho = \frac{\rho_{\text{lbm}}}{g_c} = \frac{62.4\ \frac{\text{lbm}}{\text{ft}^3}}{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} = 1.94\ \text{lbf-sec}^2/\text{ft-ft}^3$$
$$= 1.94\ \text{slugs/ft}^3$$

(b) The conversion between lbm/ft^3 and kg/m^3 is approximately 16.0, derived as follows.

$$\rho = \left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)\left(\frac{35.31\ \frac{\text{ft}^3}{\text{m}^3}}{2.205\ \frac{\text{lbm}}{\text{kg}}}\right)$$
$$= \left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)\left(16.01\ \frac{\text{kg-ft}^3}{\text{m}^3\text{-lbm}}\right) = 999\ \text{kg/m}^3$$

In SI problems, it is common to take the density of water as 1000 kg/m^3.

[3] Mass is an absolute property of a substance. Weight is not absolute, since it depends on the local gravity. Some fluids books continue to use γ as the symbol for weight density. The equations using γ that result (such as Bernoulli's equation) cannot be used with SI data, since the equations are not consistent. Thus, engineers end up with two different equations for the same thing.

SAIT - Library

5. SPECIFIC VOLUME

Specific volume, v, is the volume occupied by a unit mass of fluid.[4] Since specific volume is the reciprocal of density, typical units will be ft^3/lbm, $ft^3/lbmole$, or m^3/kg.[5]

$$v = \frac{1}{\rho} \qquad 14.6$$

6. SPECIFIC GRAVITY

Specific gravity (SG) is a dimensionless ratio of a fluid's density to some standard reference density.[6] For liquids and solids, the reference is the density of pure water. There is some variation in this reference density, however, since the temperature at which the water density is evaluated is not standardized. Temperatures of 39.2°F (4°C), 60°F, and 70°F have been reported.[7]

Fortunately, the density of water is the same to three significant digits over the normal ambient temperature range: 62.4 lbm/ft^3 or 1000 kg/m^3. However, to be precise, the temperature of both the fluid and water should be specified (e.g., "... the specific gravity of the 20°C fluid is 1.05 referred to 4°C water ...").

$$SG_{liquid} = \frac{\rho_{liquid}}{\rho_{water}} \qquad 14.7$$

Since the SI density of water is very nearly 1.000 g/cm^3 (1000 kg/m^3), the numerical values of density in g/cm^3 and specific gravity are the same. Such is not the case with English units.

The standard reference used to calculate the specific gravity of gases is the density of air. Since the density of a gas depends on temperature and pressure, both must be specified for the gas and air (i.e., two temperatures and two pressures must be specified). While STP (standard temperature and pressure) conditions are commonly specified, they are not universal.[8] Table 14.3 lists several common sets of standard conditions.

$$SG_{gas} = \frac{\rho_{gas}}{\rho_{air}} \qquad 14.8$$

Table 14.3 *Commonly Quoted Values of Standard Temperature and Pressure*

system	temperature	pressure
SI	273.15K	101.325 kPa
scientific	0.0°C	760 mm Hg
U.S. engineering	32°F	14.696 psia
natural gas industry (U.S.)	60°F	14.65, 14.73, or 15.025 psia
natural gas industry (Canada)	60°F	14.696 psia

If it is known or implied that the temperature and pressure of the air and gas are the same, the specific gravity of the gas will be equal to the ratio of molecular weights and the inverse ratio of specific gas constants. The density of air evaluated at STP is listed in Table 14.2. At 70°F (21.1°C) and 1.0 atm, the density is approximately 0.075 lbm/ft^3 (1.20 kg/m^3).

$$SG_{gas} = \frac{MW_{gas}}{MW_{air}} = \frac{MW_{gas}}{29.0} = \frac{R_{air}}{R_{gas}} = \frac{53.3\ \frac{\text{ft-lbf}}{\text{lbm-°R}}}{R_{gas}} \qquad 14.9$$

Specific gravities of petroleum liquids and aqueous solutions (of acid, antifreeze, salts, etc.) can be determined by use of a *hydrometer*. In its simplest form, a hydrometer is constructed as a graduated scale weighted at one end so it will float vertically. The height at which the hydrometer floats depends on the density of the fluid, and the graduated scale can be calibrated directly in specific gravity.[9]

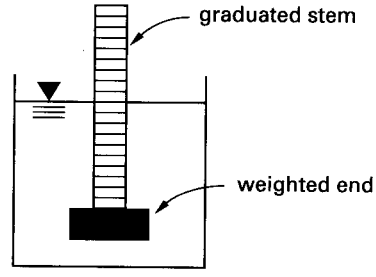

Figure 14.3 *Hydrometer*

There are two standardized hydrometer scales (i.e., methods for calibrating the hydrometer stem).[10] Both state specific gravity in degrees, although temperature is not being measured. The *American Petroleum Institute* (API) scale (°API) may be used with all liquids,

[4]Care must be taken to distinguish between the symbol upsilon, v, used for specific volume, and italic roman "vee," v, used for velocity in many engineering textbooks.
[5]Units of $ft^3/slug$ are also possible, but this combination of units is almost never encountered.
[6]The symbols S.G., sp.gr., S, and G are also used. In fact, petroleum engineers in the United States use γ, a symbol that civil engineers use for specific weight. There is no standard engineering symbol for specific gravity.
[7]Density of liquids is sufficiently independent of pressure to make consideration of pressure in specific gravity calculations unnecessary.
[8]The abbreviation "SC" (standard conditions) is interchangeable with "STP."
[9]This is a direct result of the buoyancy principle of Archimedes.
[10]In addition to °Be and °API mentioned in this chapter, the *Twaddell scale* (°Tw) is used in chemical processing, the *Brix* and *Balling's scales* are used in the sugar industry, and the *Salometer scale* is used to measure salt (NaCl and $CaCl_2$) solutions.

not only with oils or other hydrocarbons. For the specific gravity value, a standard reference temperature of 60°F (15.6°C) is implied for both the liquid and the water.

$$\text{°API} = \frac{141.5}{\text{SG}} - 131.5 \qquad 14.10$$

$$\text{SG} = \frac{141.5}{\text{°API} + 131.5} \qquad 14.11$$

The *Baumé scale* (°Be) has been used in the past. It is somewhat confusing because there are actually two Baumé scales—one for liquids heavier than water and another for liquids lighter than water. (There is also a discontinuity in the scales at SG = 1.00.) As with the API scale, the specific gravity value assumes 60°F is the standard temperature for both scales.

$$\text{SG} = \frac{140.0}{130.0 + \text{°Be}} \qquad [\text{SG} \leq 1.00] \qquad 14.12$$

$$\text{SG} = \frac{145.0}{145.0 - \text{°Be}} \qquad [\text{SG} \geq 1.00] \qquad 14.13$$

Example 14.2

Determine the specific gravity of carbon dioxide gas (molecular weight = 44) at 66°C (150°F) and 138 kPa (20 psia) using STP air as a reference.

SI Solution

$$R^* = 8314\ \text{J/kmol·K}$$

$$R = \frac{R^*}{\text{MW}} = \frac{8314\ \frac{\text{J}}{\text{kmol·K}}}{44\ \frac{\text{kg}}{\text{kmol}}} = 189.0\ \text{J/kg·K}$$

$$\rho = \frac{p}{RT} = \frac{1.38 \times 10^5\ \text{Pa}}{\left(189.0\ \frac{\text{J}}{\text{kg·K}}\right)(66°\text{C} + 273)}$$

$$= 2.15\ \text{kg/m}^3$$

$$\text{SG} = \frac{2.15\ \frac{\text{kg}}{\text{m}^3}}{1.29\ \frac{\text{kg}}{\text{m}^3}} = 1.67$$

Customary U.S. Solution

Since the conditions of the carbon dioxide and air are different, Eq. 14.8 cannot be used. It is necessary to calculate the density of the carbon dioxide from Eq. 14.5. The specific gas constant of carbon dioxide is 35.1 ft-lbf/lbm-°R. The density is

$$\rho = \frac{p}{RT} = \frac{\left(20\ \frac{\text{lbf}}{\text{in}^2}\right)\left(144\ \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(35.1\ \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(150°\text{F} + 460)}$$

$$= 0.135\ \text{lbm/ft}^3$$

From Table 14.2, the density of STP air is 0.0807 lbm/ft^3. From Eq. 14.8, the specific gravity of carbon dioxide at the conditions given is

$$\text{SG} = \frac{0.135\ \frac{\text{lbm}}{\text{ft}^3}}{0.0807\ \frac{\text{lbm}}{\text{ft}^3}} = 1.67$$

7. SPECIFIC WEIGHT

Specific weight, γ, is the weight of fluid per unit volume. The use of specific weight is most often encountered in civil engineering works from the United States, where it is commonly called "density." Mechanical and chemical engineers seldom encounter the term. The usual units of specific weight are lbf/ft^3.[11] Specific weight is not an absolute property of a fluid, since it depends not only on the fluid but on the local gravitational field as well.

$$\gamma = g\rho \qquad [\text{SI}] \qquad 14.14(a)$$

$$\gamma = \rho \times \frac{g}{g_c} \qquad [\text{U.S.}] \qquad 14.14(b)$$

If the gravitational acceleration is 32.2 ft/sec^2, as it is almost everywhere on the earth, the specific weight in lbf/ft^3 will be numerically equal to the density in lbm/ft^3. This is illustrated in Ex. 14.3.

Example 14.3

What is the sea level (g = 32.2 ft/ sec^2) specific weight (in lbf/ft^3) of liquids with densities of (a) 1.95 slug/ft^3, and (b) 58.3 lbm/ft^3?

Solution

(a) From Eq. 14.14(a),

$$\gamma = g\rho = \left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)\left(1.95\ \frac{\text{slug}}{\text{ft}^3}\right)$$

$$= \left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)\left(1.95\ \frac{\text{lbf-sec}^2}{\text{ft-ft}^3}\right) = 62.8\ \text{lbf/ft}^3$$

(b) From Eq. 14.14(b),

$$\gamma = \rho \times \frac{g}{g_c}$$

$$= \left(58.3\ \frac{\text{lbm}}{\text{ft}^3}\right)\left(\frac{32.2\ \frac{\text{ft}}{\text{sec}^2}}{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}\right) = 58.3\ \text{lbf/ft}^3$$

8. MOLE FRACTION

Mole fraction is an important parameter in many practical engineering problems, particularly in chemistry

[11] Notice that the units are lbf/ft^3, not lbm/ft^3. Pound-mass (lbm) is a mass unit, not a weight (force) unit.

and chemical engineering. The composition of a fluid consisting of two or more distinctly different substances, A, B, C, and so on, can be described by the mole fractions, x_A, x_B, x_C, and so on, of each substance.[12] The mole fraction of component A is the number of moles of that component, n_A, divided by the total number of moles in the combined fluid.

$$x_A = \frac{n_A}{n_A + n_B + n_C + \cdots} \qquad 14.15$$

Mole fraction is a number between 0 and 1.000. *Mole percent* is the mole fraction multiplied by 100, expressed in percent.

9. VISCOSITY

The *viscosity* of a fluid is a measure of that fluid's resistance to flow when acted upon by an external force such as a pressure differential or gravity. Some fluids, such as heavy oils, jellies, and syrups, are very viscous. Other fluids, such as water, lighter hydrocarbons, and gases, are not as viscous.

Most viscous liquids will flow more easily when their temperatures are raised. However, the behavior of a fluid when temperature, pressure, or stress is varied will depend on the type of fluid. The different types of fluids can be determined with a *sliding plate viscometer* test.[13]

Consider two plates of area A separated by a fluid with thickness y_0, as shown in Fig. 14.4. The bottom plate is fixed, and the top plate is kept in motion at a constant velocity, v_0, by a force, F.

Experiments with Newtonian fluids have shown that the force, F, required to maintain the velocity, v_0, is proportional to the velocity and the area and is inversely proportional to the separation of the plates. That is,

$$\frac{F}{A} \propto \frac{dv}{dy} \qquad 14.16$$

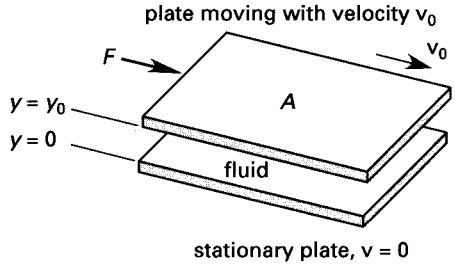

Figure 14.4 *Sliding Plate Viscometer*

The constant of proportionality needed to make Eq. 14.16 an equality is the *absolute viscosity*, μ, also known as the *coefficient of viscosity*.[14] The reciprocal of absolute viscosity, $1/\mu$, is known as the *fluidity*.

$$\frac{F}{A} = \mu \frac{dv}{dy} \qquad 14.17$$

F/A is the *fluid shear stress*, τ. The quantity dv/dy (v_0/y_0) is known by various names, including *rate of strain, shear rate, velocity gradient*, and *rate of shear formation*. Equation 14.17 is known as *Newton's law of viscosity*, from which Newtonian fluids get their name.[15] Equation 14.18 is simply the equation of a straight line.

$$\tau = \mu \frac{dv}{dy} \qquad 14.18$$

Not all fluids are Newtonian (although most common fluids are), and Eq. 14.17 is not universally applicable. Figure 14.5 illustrates how differences in fluid shear stress behavior (at constant temperature and pressure) can be used to define Bingham, pseudoplastic, and dilatant fluids, as well as Newtonian fluids.

Gases, water, alcohol, and benzene are examples of *Newtonian fluids*. In fact, all liquids with a simple chemical formula are Newtonian. Also, most solutions of simple compounds, such as sugar and salt, are Newtonian. For

[12] There are other methods of specifying the composition. The subjects of moles, mole fraction, gravimetric fraction, and volumetric fraction are covered in Chap. 22.

[13] This test is conceptually simple but is not always practical, since the liquid leaks out between the plates. In research work with liquids, it is common to determine viscosity with a *concentric cylinder viscometer*, also known as a *cup-and-bob viscometer*. Viscosities of perfect gases can be predicted by the kinetic theory of gases.

Viscosity can also be measured by a *Saybolt viscometer*, which is essentially a container that allows a given quantity of fluid to leak out through one of two different-sized orifices. The more viscous the fluid, the more time will be required for the fluid to leak out. *Saybolt Seconds Universal* (SSU) and *Saybolt Seconds Furol* (SSF) are scales of such viscosity measurement based on the smaller and larger orifices, respectively. Seconds can be converted (empirically) to viscosity in other units.

The following relations are approximate conversions between SSU, stokes, and poise.

SSU < 100 sec:

$$\nu_{\text{stokes}} = (0.00226)(\text{SSU}) - \frac{1.95}{\text{SSU}}$$

$$\mu_{\text{poise}} = (\text{SG})(\nu_{\text{stokes}})$$

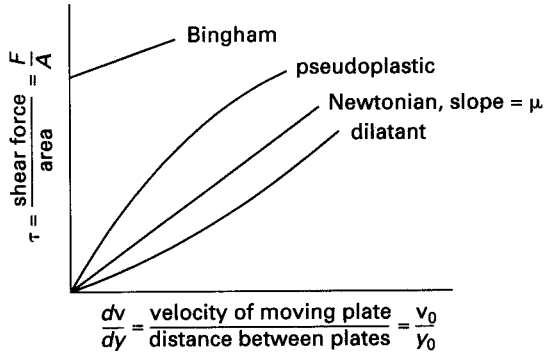
SSU > 100 sec:

$$\nu_{\text{stokes}} = (0.00220)(\text{SSU}) - \frac{1.35}{\text{SSU}}$$

$$\mu_{\text{poise}} = (\text{SG})(\nu_{\text{stokes}})$$

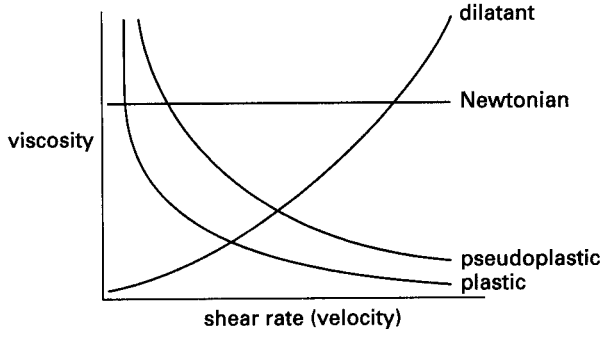
[14] Another name for absolute viscosity is *dynamic viscosity*. The name *absolute viscosity* is preferred, if for no other reason than to avoid confusion with *kinematic viscosity*.

[15] Sometimes Eq. 14.18 is written with a minus sign to compare viscous behavior with other behavior. However, the direction of positive shear stress is arbitrary.



a highly viscous fluid, the straight line (see Fig. 14.5) will be closer to the τ axis. For low-viscosity fluids, the straight line will be closer to the dv/dy axis.

Pseudoplastic fluids (muds, motor oils, polymer solutions, natural gums, and most slurries) exhibit viscosities that decrease with an increasing velocity gradient. Such fluids present no serious pumping problems.



Bingham fluids (Bingham plastics), typified by toothpaste, jellies, bread dough, and some slurries, are capable of indefinitely resisting a small shear stress but move easily when the stress becomes large—that is, Bingham fluids become pseudoplastic when the stress increases.

Dilatant fluids are rare but include clay slurries, various starches, some paints, milk chocolate with nuts, and other candy compounds. They exhibit viscosities that increase with increasing agitation (i.e., with increasing velocity gradients), but they return rapidly to their normal viscosity after the agitation ceases. Pump selection is critical for dilatant fluids because these fluids can become almost solid if the shear rate is high enough.

Plastic materials, such as tomato catsup, behave similarly to pseudoplastic fluids once movement begins—their viscosities decrease with agitation. However, a finite force must be applied before any fluid movement occurs.

(a)

(b)

Figure 14.5 *Shear Stress Behavior for Different Types of Fluids*

Viscosity can also change with time (all other conditions being constant). If viscosity decreases with time, the fluid is said to be a *thixotropic fluid.* If viscosity increases (usually up to a finite value) with time, the fluid is a *rheopectic fluid.* Viscosity does not change in time-independent fluids. *Colloidal materials*, such as gelatinous compounds, lotions, shampoos, and low-temperature solutions of soaps in water and oil, behave like *thixotropic liquids*—their viscosities decrease as the rate of shear is increased. However, viscosity does not return to its original state after the agitation ceases.

Molecular cohesion is the dominating cause of viscosity in liquids. As the temperature of a liquid increases, these cohesive forces decrease, resulting in a decrease in viscosity.

In gases, the dominant cause of viscosity is random collisions between gas molecules. This molecular agitation increases with increases in temperature. Therefore, viscosity in gases increases with temperature.

Although viscosity of liquids increases slightly with pressure, the increase is insignificant over moderate pressure ranges. Therefore, the absolute viscosity of both gases and liquids is usually considered to be essentially independent of pressure.[16]

The units of absolute viscosity, as derived from Eq. 14.18, are lbf-sec/ft^2. Such units are actually used in the English engineering system.[17] Another common unit used throughout the world is the *poise* (abbreviated P), equal to a dyne·s/cm^2. These dimensions are the same primary dimensions as in the English system, $F\theta/L^2$ or $M/L\theta$, and are functionally the same as a g/cm·s. Since the poise is a large unit, the *centipoise* (abbreviated cP) scale is generally used. By coincidence, the viscosity of pure water at room temperature is approximately 1 cP.

Absolute viscosity is measured in pascal-seconds (Pa·s) in SI units.

Example 14.4

A liquid ($\mu = 5.2 \times 10^{-5}$ lbf-sec/ft^2) is flowing in a rectangular duct. The equation of the symmetrical velocity (in ft/sec) is approximately $v = 3y^{0.7}$ ft/sec, where y is in inches. (a) What is the velocity gradient at $y = 3.0$ in from the duct wall? (b) What is the shear stress in the fluid at that point?

Solution

(a) The velocity is not a linear function of y, so dv/dy must be calculated as a derivative.

$$\frac{dv}{dy} = \frac{d}{dy}\left(3y^{0.7}\right)$$

$$= (3)\left(0.7y^{-0.3}\right) = 2.1y^{-0.3}$$

[16]This is not true for kinematic viscosity, however.

[17]Units of lbm/ft-sec are also used for absolute viscosity in the English system, although it is difficult to see how such units are derived from the sliding-plate test. These units are obtained by dividing lbf-sec/ft^2 units by g_c.

At $y = 3$ in,

$$\frac{dv}{dy} = (2.1)\left(3^{-0.3}\right) = 1.51 \text{ ft/sec-in}$$

(b) From Eq. 14.18, the shear stress is

$$\begin{aligned}\tau &= \mu\frac{dv}{dy} \\ &= \left(5.2 \times 10^{-5}\ \frac{\text{lbf-sec}}{\text{ft}^2}\right)\left(1.51\ \frac{\text{ft}}{\text{sec-in}}\right)\left(12\ \frac{\text{in}}{\text{ft}}\right) \\ &= 9.42 \times 10^{-4}\ \text{lbf/ft}^2\end{aligned}$$

10. KINEMATIC VISCOSITY

Another quantity with the name *viscosity* is the ratio of absolute viscosity to mass density. This combination of variables, known as *kinematic viscosity*, ν, appears sufficiently often in fluids and other problems as to warrant its own symbol and name. Thus, kinematic viscosity is the name given to a frequently occurring combination of variables.

$$\nu = \frac{\mu}{\rho} \qquad \text{[SI]} \qquad 14.19(a)$$

$$\nu = \frac{\mu g_c}{\rho} \qquad \text{[U.S.]} \qquad 14.19(b)$$

The primary dimensions of kinematic viscosity are L^2/θ. Typical units are ft^2/sec and cm^2/s (the *stoke*, St). It is also common to give kinematic viscosity in *centistokes*, cSt. The SI units of kinematic viscosity are m^2/s.

It is essential that consistent units be used with Eq. 14.19(a). The following sets of units are consistent:

$$\text{ft}^2/\text{sec} = \frac{\text{lbf-sec/ft}^2}{\text{slugs/ft}^3}$$

$$\text{m}^2/\text{s} = \frac{\text{Pa·s}}{\text{kg/m}^3}$$

$$\text{St (stoke)} = \frac{\text{P (poise)}}{\text{g/cm}^3}$$

$$\text{cSt (centistokes)} = \frac{\text{cP (centipoise)}}{\text{g/cm}^3}$$

Unlike absolute viscosity, kinematic viscosity is greatly dependent on both temperature and pressure, since these variables affect the density of the fluid. Referring to Eq. 14.19, even if absolute viscosity is independent of temperature or pressure, the change in density will change the kinematic viscosity.

11. VISCOSITY CONVERSIONS

The most common units of absolute and kinematic viscosity are listed in Table 14.4.

Table 14.4 *Common Viscosity Units*

	absolute (μ)	kinematic (ν)
English	lbf-sec/ft^2 (slug/ft-sec)	ft^2/sec
conventional metric	dyne·s/cm^2 (poise)	cm^2/s (stoke)
SI	Pa·s (N·s/m^2)	m^2/s

Table 14.5 contains conversions between the various viscosity units.

Table 14.5 *Viscosity Conversions*[a]

multiply	by	to obtain
absolute viscosity, μ		
dyne·s/cm^2	0.10	Pa·s
lbf-sec/ft^2	478.8	P
lbf-sec/ft^2	47,880	cP
lbf-sec/ft^2	47.88	Pa·s
slug/ft-sec	47.88	Pa·s
lbm/ft-sec	1.488	Pa·s
cP	1.0197×10^{-4}	kgf·s/m^2
cP	2.0885×10^{-5}	lbf-sec/ft^2
cP	0.001	Pa·s
Pa·s	0.020885	lbf-sec/ft^2
Pa·s	1000	cP
kinematic viscosity, ν		
ft^2/sec	92,903	cSt
ft^2/sec	0.092903	m^2/s
m^2/s	10.7639	ft^2/sec
m^2/s	1×10^6	cSt
cSt	1×10^{-6}	m^2/sec
cSt	1.0764×10^{-5}	ft^2/sec
absolute viscosity to kinematic viscosity		
cP	$1/\rho$ in g/cm^3	cSt
cP	$6.7195 \times 10^{-4}/\rho$ in lbm/ft^3	ft^2/sec
lbf-sec/ft^2	$32.174/\rho$ in lbm/ft^3	ft^2/sec
kgf·s/m^2	$9.807/\rho$ in kg/m^3	m^2/s
Pa·s	$1000/\rho$ in g/cm^3	cSt
kinematic viscosity to absolute viscosity		
cSt	ρ in g/cm^3	cP
cSt	$0.001 \times \rho$ in lbm/ft^3	Pa·s
m^2/s	$0.10197 \times \rho$ in kg/m^3	kgf·s/m^2
m^2/s	$1000 \times \rho$ in g/cm^3	Pa·s
ft^2/sec	$0.031081 \times \rho$ in lbm/ft^3	lbf-sec/ft^2
ft^2/sec	$1488.2 \times \rho$ in lbm/ft^3	cP

[a] cP: centipoise; cSt: centistoke; P: poise

Example 14.5

Water at 60°F has a specific gravity of 0.999 and a kinematic viscosity of 1.12 cSt. What is the absolute viscosity in lbf-sec/ft^2?

Solution

The density of a liquid expressed in g/cm^3 is numerically equal to its specific gravity.

$$\rho = 0.999\,\text{g/cm}^3$$

The centistoke (cSt) is a measure of kinematic viscosity. Kinematic viscosity is converted first to the absolute viscosity units of centipoise. From Table 14.5,

$$\begin{aligned}\mu_{\text{cP}} &= \nu_{\text{cSt}}\,\rho_{\text{g/cm}^3} \\ &= (1.12)(0.999) = 1.119\,\text{cP}\end{aligned}$$

Next, centipoises are converted to lbf-sec/ft^2.

$$\begin{aligned}\mu_{\text{lbf-sec/ft}^2} &= \mu_{\text{cP}}\left(2.0885 \times 10^{-5}\right) \\ &= (1.119)\left(2.0885 \times 10^{-5}\right) \\ &= 2.34 \times 10^{-5}\ \text{lbf-sec/ft}^2\end{aligned}$$

12. VISCOSITY INDEX

Viscosity index (VI) is a measure of a fluid's sensitivity to changes in viscosity with changes in temperature. It has traditionally been applied to crude and refined oils through use of a 100-point scale.[18] The viscosity is measured at two temperatures: 100°F and 210°F (38°C and 99°C). These temperatures are converted into a viscosity index in accordance with standard ASTM D2270.

13. VAPOR PRESSURE

Molecular activity in a liquid will allow some of the molecules to escape the liquid surface. Strictly speaking, a small portion of the liquid vaporizes. Molecules of the vapor also condense back into the liquid. The vaporization and condensation at constant temperature are equilibrium processes. The equilibrium pressure exerted by these free molecules is known as the *vapor pressure* or *saturation pressure*. (Vapor pressure does not include the pressure of other substances in the mixture.)

Some liquids, such as propane, butane, ammonia, and Freon, have significant vapor pressures at normal temperatures. Liquids near their boiling points or that vaporize easily are said to be *volatile liquids*.[19] Other liquids, such as mercury, have insignificant vapor pressures at the same temperature. Liquids with low vapor pressures are used in accurate barometers.

The tendency toward vaporization is dependent on the temperature of the liquid. *Boiling* occurs when the liquid temperature is increased to the point that the vapor pressure is equal to the local ambient pressure. Thus, a liquid's boiling temperature depends on the local ambient pressure as well as on the liquid's tendency to vaporize.

Vapor pressure is usually considered to be a nonlinear function of temperature only. It is possible to derive correlations between vapor pressure and temperature, and such correlations usually involve a logarithmic transformation of vapor pressure.[20] Vapor pressure can also be graphed against temperature in a (logarithmic) *Cox chart* when values are needed over larger temperature extremes. Although there is also some variation with external pressure, the external pressure effect is negligible under normal conditions.

Typical values of vapor pressure are given in Table 14.6.

Table 14.6 *Typical Vapor Pressures*

fluid	lbf/ft^2, 68°F	kPa, 20°C
mercury	0.00362	0.000173
turpentine	1.115	0.0534
water	48.9	2.34
ethyl alcohol	122.4	5.86
ether	1231	58.9
butane	4550	218
Freon-12	12,200	584
propane	17,900	855
ammonia	18,550	888

14. OSMOTIC PRESSURE

Osmosis is a special case of diffusion in which molecules of the *solvent* move from one fluid to another (i.e., from the *solvent* to the *solution*) in one direction only, usually through a *semipermeable membrane*.[21] Osmosis continues until sufficient solvent has passed through the membrane to make the activity (or solvent pressure) of the solution equal to that of the solvent.[22] The pressure at equilibrium is known as the *osmotic pressure*, π.

[18]Use of the *viscosity index* has been adopted by other parts of the chemical process industry (CPI), including in the manufacture of solvents, polymers, and other synthetics. The 100-point scale may be exceeded (on both ends) for these uses. Refer to standard ASTM D2270 for calculating extreme values of the viscosity index.

[19]Because a liquid that vaporizes easily has an aroma, the term *aromatic liquid* is also occasionally used.

[20]The *Clausius-Clapeyron equation* and *Antoine equation* are two such logarithmic correlations of vapor pressure with temperature.

[21]A semipermeable membrane will be impermeable to the solute but permeable for the solvent.

[22]Two solutions in equilibrium (i.e., whose activities are equal) are said to be in *isopiestic equilibrium*.

Figure 14.6 illustrates an *osmotic pressure apparatus.* The fluid column can be interpreted as the result of an osmotic pressure that has developed through diffusion into the solution. The fluid column will continue to increase in height until equilibrium is reached. Alternatively, the fluid column can be adjusted so that the solution pressure just equals the osmotic pressure that would develop otherwise, in order to prevent the flow of solvent. For the arrangement in Fig. 14.6, the osmotic pressure can be calculated from the difference in fluid level heights.

$$\pi = \rho g h \qquad \text{[SI]} \qquad 14.20(a)$$

$$\pi = \frac{\rho g h}{g_c} \qquad \text{[U.S.]} \qquad 14.20(b)$$

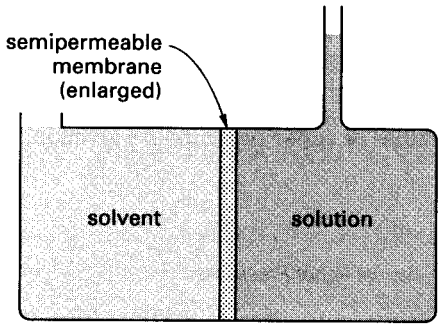


Figure 14.6 *Osmotic Pressure Apparatus*

In dilute solutions, osmotic pressure obeys the ideal gas law. The solute acts like a gas in exerting pressure against the membrane. The solvent exerts no pressure since it can pass through. In Eq. 14.21, M is the molarity (concentration). Consistent units must be used.

$$\pi = MR^*T \qquad 14.21$$

Example 14.6

An aqueous solution is in isopiestic equilibrium with a 0.1 molarity sucrose solution at 22°C. What is the osmotic pressure?

Solution

Referring to Eq. 14.21,

$$M = 0.1 \text{ mol/L of solution}$$

$$R^* = 0.0821 \text{ atm·L/mol·K}$$

$$T = 22°\text{C} + 273 = 295\text{K}$$

$$\pi = MR^*T = \left(0.1 \frac{\text{mol}}{\text{L}}\right)\left(0.0821 \frac{\text{atm·L}}{\text{mol·K}}\right)(295\text{K})$$

$$= 2.42 \text{ atm}$$

15. SURFACE TENSION

The membrane or "skin" that seems to form on the free surface of a fluid is due to the intermolecular cohesive forces and is known as *surface tension*, σ. Surface tension is the reason that insects are able to sit on water and a needle is able to float on it. Surface tension also causes bubbles and droplets to take on a spherical shape, since any other shape would have more surface area per unit volume.

Data on the surface tension of liquids is important in determining the performance of heat-, mass-, and momentum-transfer equipment, including heat transfer devices.[23] Surface tension data is needed to calculate the nucleate boiling point (i.e., the initiation of boiling) of liquids in a pool (using the *Rohsenow equation*) and the maximum heat flux of boiling liquids in a pool (using the *Zuber equation*).

Surface tension can be interpreted as the tension between two points a unit distance apart on the surface or as the amount of work required to form a new unit of surface area in an apparatus similar to that shown in Fig. 14.7. Typical units of surface tension are lbf/ft (ft-lbf/ft^2), dyne/cm, and N/m.

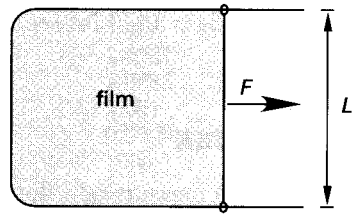

Figure 14.7 *Wire Frame for Stretching a Film*

The apparatus shown in Fig. 14.7 consists of a wire frame with a sliding side that has been dipped in a liquid to form a film. Surface tension is determined by measuring the force necessary to keep the sliding side stationary, against the surface tension pull of the film.[24] (The film does not act like a spring, since the force, F, does not increase as the film is stretched.) Since the film has two surfaces (i.e., two surface tensions), the surface tension is

$$\sigma = \frac{F}{2L} \qquad 14.22$$

Alternatively, surface tension can also be determined by measuring the force required to pull a wire ring out of the liquid, as shown in Fig. 14.8.[25] Since the ring's inner and outer sides are in contact with the liquid,

[23]Surface tension plays a role in processes involving dispersion, emulsion, flocculation, foaming, and solubilization. It is not surprising that surface tension data are particularly important in determining the performance of equipment in the chemical process industry (CPI), such as distillation columns, packed towers, wetted-wall columns, strippers, and phase-separation equipment.

[24]The force includes the weight of the sliding side wire if the frame is oriented vertically, with gravity acting on the sliding side wire to stretch the film.

[25]This apparatus is known as a *Du Novy torsion balance.* The ring is made of platinum with a diameter of 4.00 cm.

the wetted perimeter is twice the circumference. The surface tension is

$$\sigma = \frac{F}{4\pi r} \qquad 14.23$$

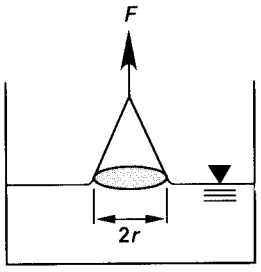

Figure 14.8 *Du Novy Ring Surface Tension Apparatus*

Surface tension depends slightly on the gas in contact with the free surface. Surface tension values are usually quoted for air contact. Typical values of surface tension are listed in Table 14.7.

Table 14.7 *Approximate Values of Surface Tension (air contact)*

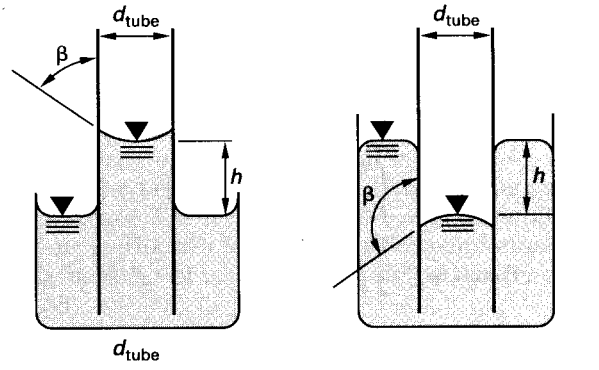
fluid	lbf/ft, 68°F	N/m, 20°C
n-octane	0.00149	0.0217
ethyl alcohol	0.00156	0.0227
acetone	0.00162	0.0236
kerosene	0.00178	0.0260
carbon tetrachloride	0.00185	0.0270
turpentine	0.00186	0.0271
toluene	0.00195	0.0285
benzene	0.00198	0.0289
olive oil	0.0023	0.034
glycerin	0.00432	0.0631
water	0.00499	0.0728
mercury	0.0356	0.519

(Multiply lbf/ft by 14.59 to obtain N/m.)
(Multiply dyne/cm by 0.001 to obtain N/m.)

At temperatures below freezing, the substance will be a solid, so surface tension is a moot point. As the temperature of a liquid is raised, the surface tension decreases because the cohesive forces decrease. Surface tension is zero at a substance's critical temperature. If a substance's critical temperature is known, the *Othmer correlation*, Eq. 14.24, can be used to determine the surface tension at one temperature from the surface tension at another temperature.[26]

$$\sigma_2 = \sigma_1 \left[\frac{T_c - T_2}{T_c - T_1}\right]^{\frac{11}{9}} \qquad 14.24$$

[26] An extensive listing of critical temperatures and surface tension data was presented in "633 Organic Chemicals: Surface Tension Data," *Chemical Engineering Magazine*, March 1991, pp. 140–150.



Surface tension is the reason that the pressure on the inside of bubbles and droplets is greater than on the outside. Equation 14.25 gives the relationship between the surface tension in a hollow bubble surrounded by a gas and the difference between the inside and outside pressures. For a spherical droplet or a bubble in a liquid, where in both cases there is only one surface in tension, the surface tension is twice as large. (r is the radius of the bubble or droplet.)

$$\sigma_{\text{bubble}} = \frac{r(p_{\text{inside}} - p_{\text{outside}})}{4} \qquad 14.25$$

$$\sigma_{\text{droplet}} = \frac{r(p_{\text{inside}} - p_{\text{outside}})}{2} \qquad 14.26$$

16. CAPILLARY ACTION

Capillary action (capillarity) is the name given to the behavior of a liquid in a thin-bore tube. Capillary action is caused by surface tension between the liquid and a vertical solid surface.[27] In water, the adhesive forces between the liquid molecules and the surface are greater than (i.e., dominate) the cohesive forces between the water molecules themselves.[28] The adhesive forces cause the water to attach itself to and climb a solid vertical surface. It can be said that the water "reaches up and tries to wet as much of the interior surface as it can." In so doing, the water rises above the general water surface level. This is illustrated in Fig. 14.9.

(a) adhesive force dominates (b) cohesive force dominates

Figure 14.9 *Capillarity of Liquids*

Figure 14.9 also illustrates that the same surface tension forces that keep a droplet spherical are at work on the surface of the liquid in the tube. The curved liquid surface, known as the *meniscus*, can be considered to be an incomplete droplet. If the inside diameter of the tube is less than approximately 0.1 in (2.5 mm), the meniscus is essentially hemispherical, and $r_{\text{meniscus}} = r_{\text{tube}}$.

[27] In fact, observing the rise of liquid in a capillary tube is another method of determining the surface tension of a liquid.

[28] *Adhesion* is the attractive force between molecules of different substances. *Cohesion* is the attractive force between molecules of the same substance.

For a few other liquids, such as mercury, the molecules have a strong affinity for each other (i.e., the cohesive forces dominate). The liquid avoids contact with the tube surface. In such liquids, the meniscus will be below the general surface level.

Table 14.8 *Contact Angles, β*

materials	angle
mercury–glass	140°
water–paraffin	107°
water–silver	90°
kerosene–glass	26°
glycerin–glass	19°
water–glass	0°
ethyl alcohol–glass	0°

The *angle of contact*, β, is an indication of whether adhesive or cohesive forces dominate. For contact angles less than 90°, adhesive forces dominate. For contact angles greater than 90°, cohesive forces dominate.

Equation 14.27 can be used to predict the capillary rise in a small-bore tube. Surface tension and contact angles can be obtained from Tables 14.7 and 14.8, respectively.

$$h = \frac{4\sigma\cos\beta}{\rho d_{\text{tube}}\, g} \qquad \text{[SI]} \quad \textit{14.27(a)}$$

$$h = \left(\frac{4\sigma\cos\beta}{\rho d_{\text{tube}}}\right) \times \left(\frac{g_c}{g}\right) \qquad \text{[U.S.]} \quad \textit{14.27(b)}$$

$$\sigma = \frac{h\rho d_{\text{tube}}\, g}{4\cos\beta} \qquad \text{[SI]} \quad \textit{14.28(a)}$$

$$\sigma = \left(\frac{h\rho d_{\text{tube}}}{4\cos\beta}\right) \times \left(\frac{g}{g_c}\right) \qquad \text{[U.S.]} \quad \textit{14.28(b)}$$

$$r_{\text{meniscus}} = \frac{d_{\text{tube}}}{2\cos\beta} \qquad \textit{14.29}$$

If it is assumed that the meniscus is hemispherical, then $r_{\text{meniscus}} = r_{\text{tube}}$, $\beta = 0°$, and $\cos\beta = 1.0$, and the above equations can be simplified. (Such an assumption can only be made when the diameter of the capillary tube is less than 0.1 in.)

Example 14.7

To what height will 20°C (68°F) ethyl alcohol rise in a 0.005 in (0.127 mm) internal diameter glass capillary tube? The density of the alcohol is 790 kg/m^3 (49 lbm/ft^3).

SI Solution

$$\sigma = 0.0227 \text{ N/m}$$

$$\beta = 0°$$

The acceleration due to gravity is 9.81 m/s^2. From Eq. 14.27, the height is

$$h = \frac{4\sigma\cos\beta}{\rho d_{\text{tube}}\, g}$$

$$= \frac{(4)\left(0.0227\ \frac{\text{N}}{\text{m}}\right)(1.0)\left(1000\ \frac{\text{mm}}{\text{m}}\right)}{\left(790\ \frac{\text{kg}}{\text{m}^3}\right)(0.127\text{ mm})\left(9.81\ \frac{\text{m}}{\text{sec}^2}\right)}$$

$$= 0.0923 \text{ m}$$

Customary U.S. Solution

From Tables 14.7 and 14.8, respectively, the surface tension and contact angle are

$$\sigma = 0.00156 \text{ lbf/ft}$$

$$\beta = 0°$$

The acceleration due to gravity is 32.2 ft/sec^2. From Eq. 14.27, the height is

$$h = \frac{4\sigma\cos\beta g_c}{\rho d_{\text{tube}}\, g}$$

$$= \frac{(4)\left(0.00156\ \frac{\text{lbf}}{\text{ft}}\right)(1.0)\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)\left(12\ \frac{\text{in}}{\text{ft}}\right)}{\left(49\ \frac{\text{lbm}}{\text{ft}^3}\right)(0.005\text{ in})\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}$$

$$= 0.306 \text{ ft}$$

17. COMPRESSIBILITY[29]

Compressibility (also known as the *coefficient of compressibility*), β, is the fractional change in the volume of a fluid per unit change in pressure in a constant-temperature process.[30] Typical units are 1/psi, 1/psf, 1/atm, and 1/kPa. It is the reciprocal of the bulk modulus, a quantity that is more commonly tabulated than compressibility.

$$\beta = \frac{-\frac{\Delta V}{V_0}}{\Delta p} = \frac{1}{E} \qquad \textit{14.30}$$

Compressibility can also be written in terms of partial derivatives.

$$\beta = \left(\frac{-1}{V_0}\right)\left(\frac{\partial V}{\partial p}\right)_T = \left(\frac{1}{\rho_0}\right)\left(\frac{\partial \rho}{\partial p}\right)_T \qquad \textit{14.31}$$

[29] Compressibility should not be confused with the *thermal coefficient of expansion*, $(1/V_0)\,(\partial V/\partial T)_p$, which is the fractional change in volume per unit temperature change in a constant-pressure process (with units of 1/°F or 1/°C), or the dimensionless *compressibility factor*, Z, used with the ideal gas law.

[30] Other symbols used for compressibility are c, C, and K. Equation 14.30 is written with a negative sign to show that volume decreases as pressure increases.

Compressibility changes only slightly with temperature. The small compressibility of liquids is typically considered to be insignificant, giving rise to the common understanding that liquids are incompressible.

The density of a compressible fluid depends on the fluid's pressure. For small changes in pressure, the density at one pressure can be calculated from the density at another pressure from Eq. 14.32.

$$\rho_2 \approx \rho_1[1 + \beta(p_2 - p_1)] \qquad 14.32$$

Gases, of course, are easily compressed. The compressibility of an ideal gas depends on its pressure, p, its ratio of specific heats, k, and the nature of the process.[31] Depending on the process, the compressibility may be known as *isothermal compressibility* or *(adiabatic) isentropic compressibility.* Of course, compressibility is zero for constant-volume processes and is infinite (or undefined) for constant-pressure processes.

$$\beta_T = \frac{1}{p} \quad \text{[isothermal ideal gas processes]} \qquad 14.33$$

$$\beta_s = \frac{1}{kp} \quad \text{[adiabatic ideal gas processes]} \qquad 14.34$$

Table 14.9 *Approximate Compressibility of Common Liquids at 1 atm*

liquid	temperature	β, 1/psi	β, 1/atm
mercury	32°F	0.027×10^{-5}	0.39×10^{-5}
glycerin	60°F	0.16×10^{-5}	2.4×10^{-5}
water	60°F	0.33×10^{-5}	4.9×10^{-5}
ethyl alcohol	32°F	0.68×10^{-5}	10×10^{-5}
chloroform	32°F	0.68×10^{-5}	10×10^{-5}
gasoline	60°F	1.0×10^{-5}	15×10^{-5}
hydrogen	20K	11×10^{-5}	160×10^{-5}
helium	2.1K	48×10^{-5}	700×10^{-5}

(Multiply 1/psi by 0.14504 to obtain 1/kPa.)
(Multiply 1/psi by 14.696 to obtain 1/atm.)

Example 14.8

Water at 20°C (68°F) and 1 atm has a density of 997 kg/m^3 (62.3 lbm/ft^3). What is the new density if the pressure is isothermally increased from 100 kPa (14.7 psi) to 2760 kPa (400 psi)? Assume that the bulk modulus has a constant value of 2.2×10^6 kPa (320,000 psi).

SI Solution

Compressibility is the reciprocal of the bulk modulus.

$$\beta = \frac{1}{E} = \frac{1}{2.2 \times 10^6 \text{ kPa}} = 4.55 \times 10^{-7} \text{ 1/kPa}$$

All other information needed to use Eq. 14.32 is provided.

$$\begin{aligned}\rho_2 &= \rho_1[1 + \beta(p_2 - p_1)] \\ &= \left(997 \frac{\text{kg}}{\text{m}^3}\right)\left[1 + \left(4.55 \times 10^{-7} \frac{1}{\text{kPa}}\right)\right. \\ &\quad \left.\times(2760 \text{ kPa} - 100 \text{ kPa})\right] \\ &= 998.2 \text{ kg/m}^3\end{aligned}$$

Customary U.S. Solution

Compressibility is the reciprocal of the bulk modulus.

$$\beta = \frac{1}{E} = \frac{1}{320{,}000 \frac{\text{lbf}}{\text{in}^2}} = 0.3125 \times 10^{-5} \text{ in}^2/\text{lbf}$$

All other information needed to use Eq. 14.32 is provided.

$$\begin{aligned}\rho_2 &= \rho_1 [1 + \beta(p_2 - p_1)] \\ &= \left(62.3 \frac{\text{lbm}}{\text{ft}^3}\right)\left[1 + \left(0.3125 \times 10^{-5} \frac{\text{in}^2}{\text{lbf}}\right)\right. \\ &\quad \left.\times \left(400 \frac{\text{lbf}}{\text{in}^2} - 14.7 \frac{\text{lbf}}{\text{in}^2}\right)\right] \\ &= 62.38 \text{ lbm/ft}^3\end{aligned}$$

18. BULK MODULUS

The *bulk modulus*, E, of a fluid is analogous to the modulus of elasticity of a solid.[32] Typical units are psi, atm, and kPa. The term Δp in Eq. 14.35 represents an increase in stress. The term $\Delta V/V_0$ is a *volumetric strain.* Analogous to Hooke's law describing elastic formation, the *bulk modulus* of a fluid (liquid or gas) is given by Eq. 14.35.

$$E = \frac{\text{stress}}{\text{strain}} = \frac{-\Delta p}{\frac{\Delta V}{V_0}} \qquad 14.35(a)$$

$$E = -V_0 \left(\frac{\partial p}{\partial V}\right)_T \qquad 14.35(b)$$

The term *secant bulk modulus* is associated with Eq. 14.35(a) (using finite differences), while the terms *tangent bulk modulus* and *point bulk modulus* are associated with Eq. 14.35(b) (using partial derivatives).

The bulk modulus is the reciprocal of compressibility.

$$E = \frac{1}{\beta} \qquad 14.36$$

[31] For air, $k = 1.4$.

[32] To distinguish it from the modulus of elasticity, the bulk modulus is represented by the symbol B when dealing with solids.

The bulk modulus changes only slightly with temperature. Water's bulk modulus is usually taken as 300,000 psi (2.1×10^6 kPa) unless greater accuracy is required, in which case Table 14.10 or App. 14.A can be used.

Table 14.10 *Approximate Bulk Modulus of Water*

pressure (psi)	32°F	68°F	120°F	200°F	300°F
	(thousands of psi)				
15	292	320	332	308	–
1500	300	330	340	319	218
4500	317	348	362	338	271
15,000	380	410	420	405	350

(Multiply psi by 6.8948 to obtain kPa.)

19. SPEED OF SOUND

The *speed of sound* (*acoustical velocity* or *sonic velocity*), a, in a fluid is a function of its bulk modulus (or, equivalently, of its compressibility).[33] Equation 14.37 gives the speed of sound through a liquid.

$$a = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{1}{\beta\rho}} \quad \text{[SI]} \qquad 14.37(a)$$

$$a = \sqrt{\frac{Eg_c}{\rho}} = \sqrt{\frac{g_c}{\beta\rho}} \quad \text{[U.S.]} \qquad 14.37(b)$$

Equation 14.38 gives the speed of sound in an ideal gas. The temperature, T, must be in degrees absolute (i.e., °R or K). For air, the ratio of specific heats is $k = 1.40$, the molecular weight is 29.0, and the universal gas constant is $R^* = 1545.3$ ft-lbf/lbmol-°R (8314 J/kmol·K).

$$a = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{kp}{\rho}}$$

$$= \sqrt{kRT} = \sqrt{\frac{kR^*T}{\text{MW}}} \quad \text{[SI]} \qquad 14.38(a)$$

$$a = \sqrt{\frac{Eg_c}{\rho}} = \sqrt{\frac{kg_cp}{\rho}}$$

$$= \sqrt{kg_cRT} = \sqrt{\frac{kg_cR^*T}{\text{MW}}} \quad \text{[U.S.]} \qquad 14.38(b)$$

Since k and R are constant for an ideal gas, the speed of sound is a function of temperature only. Equation 14.39 can be used to calculate the new speed of sound when temperature is varied.

$$\frac{a_1}{a_2} = \sqrt{\frac{T_1}{T_2}} \qquad 14.39$$

[33]The symbol c is also used for the sonic velocity.

The *Mach number* of an object is the ratio of the object's speed to the speed of sound in the medium through which it is traveling.

$$\text{M} = \frac{\text{v}}{a} \qquad 14.40$$

The term *subsonic travel* implies $\text{M} < 1$.[34] Similarly, *supersonic travel* implies $\text{M} > 1$, but usually $\text{M} < 5$. Travel above $\text{M} = 5$ is known as *hypersonic travel*. Travel in the transition region between subsonic and supersonic (i.e., $0.8 < \text{M} < 1.2$) is known as *transonic travel*. A *sonic boom* (a shock-wave phenomenon) occurs when an object travels at supersonic speed.

Example 14.9

What is the velocity of sound in 150°F (66°C) water? The density is 61.2 lbm/ft^3 (980 kg/m^3), and the bulk modulus is 328,000 psi (2.26×10^6 kPa).

SI Solution

$$a = \sqrt{\frac{(2.26 \times 10^6 \text{ kPa})\left(1000 \dfrac{\text{Pa}}{\text{kPa}}\right)}{980 \dfrac{\text{kg}}{\text{m}^3}}} = 1519 \text{ m/s}$$

Customary U.S. Solution

From Eq. 14.37,

$$a = \sqrt{\frac{Eg_c}{\rho}}$$

$$= \sqrt{\frac{\left(328{,}000 \dfrac{\text{lbf}}{\text{in}^2}\right)\left(144 \dfrac{\dfrac{\text{lbf}}{\text{ft}^2}}{\dfrac{\text{lbf}}{\text{in}^2}}\right)\left(32.2 \dfrac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)}{61.2 \dfrac{\text{lbm}}{\text{ft}^3}}}$$

$$= 4985 \text{ ft/sec}$$

Example 14.10

What is the velocity of sound in 150°F (66°C) air at standard atmospheric pressure?

SI Solution

$$R = \frac{8314 \dfrac{\text{J}}{\text{kmol·K}}}{29 \dfrac{\text{kg}}{\text{kmol}}} = 286.7 \text{ J/kg·K}$$

$$T = 66°\text{C} + 273 = 339\text{K}$$

$$a = \sqrt{kg_cRT} = \sqrt{(1.4)\left(286.7 \dfrac{\text{J}}{\text{kg·K}}\right)(339\text{K})}$$

$$= 369 \text{ m/s}$$

[34]In the language of compressible fluid flow, this is known as the *subsonic flow regime*.

Customary U.S. Solution

The specific gas constant, R, for air is

$$R = \frac{R^*}{\text{MW}} = \frac{1545.3\ \frac{\text{ft-lbf}}{\text{lbmol-°R}}}{29.0\ \frac{\text{lbm}}{\text{lbmol}}}$$
$$= 53.3\ \text{ft-lbf/lbm-°R}$$

The absolute temperature is

$$T = 150°\text{F} + 460 = 610°\text{R}$$

From Eq. 14.38(b),

$$a = \sqrt{kg_cRT}$$
$$= \sqrt{(1.4)\left(32.2\ \frac{\text{ft-lbm}}{\text{lbf-sec}^2}\right)\left(53.3\ \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(610°\text{R})}$$
$$= 1211\ \text{ft/sec}$$

20. PROPERTIES OF SOLUTIONS

There are few convenient ways of predicting the properties of nonreacting, nonvolatile organic and aqueous solutions (acids, brines, alcohol mixtures, coolants, etc.) and mixtures from the individual properties of the components.

Volumes of two combining organic liquids (e.g., acetone and chloroform) are essentially additive. The volume change upon mixing will seldom be more than a few tenths of a percent. The volume change in aqueous solutions is often slightly greater, but is still limited to a few percent (e.g., 3% for some solutions of methanol and water).

Thus, the specific gravity (density, specific weight, etc.) can be considered to be a volumetric weighting of the individual specific gravities. Most times, however, the specific gravity of a known solution must be calculated from known data regarding one of the various density scales (see Sec. 6) or determined through research.

Most other important fluid properties of aqueous solutions, such as viscosity, compressibility, surface tension, and vapor pressure, have been measured and are usually determined through research.[35] It is important to be aware of the operating conditions of the solution. Data for one concentration or condition should not be used for another concentration or condition.

[35]There is no substitute for a complete fluid properties data book.

PRACTICE PROBLEMS

(Use $g = 32.2\ \text{ft/sec}^2$ or $9.81\ \text{m/s}^2$ unless told to do otherwise in the problem.)

Pressure

1. What is the absolute pressure if a gauge reads 8.7 psi (60 kPa) vacuum?

(A) 4 psi (27 kPa)
(B) 6 psi (41 kPa)
(C) 8 psi (55 kPa)
(D) 10 psi (68 kPa)

The answer is (B).

Viscosity

2. Calculate the kinematic viscosity of air at 80°F (27°C) and 70 psia (480 kPa).

(A) $3.54 \times 10^{-5}\ \text{ft}^2/\text{sec}$ ($3.30 \times 10^{-6}\ \text{m}^2/\text{s}$)
(B) $4.25 \times 10^{-5}\ \text{ft}^2/\text{sec}$ ($3.96 \times 10^{-6}\ \text{m}^2/\text{s}$)
(C) $4.96 \times 10^{-5}\ \text{ft}^2/\text{sec}$ ($4.62 \times 10^{-6}\ \text{m}^2/\text{s}$)
(D) $6.37 \times 10^{-5}\ \text{ft}^2/\text{sec}$ ($5.94 \times 10^{-6}\ \text{m}^2/\text{s}$)

The answer is (A).

Solutions

3. Volumes of an 8% solution, a 10% solution, and a 20% solution of nitric acid are to be mixed in order to get 100 mL of a 12% solution. If the 8% solution contributes half of the volume of nitric acid contributed by the 10% and 20% solutions, what volume of 10% acid solution is required?

(A) 20 mL
(B) 30 mL
(C) 50 mL
(D) 80 mL

The answer is (A).

1. PRESSURE-MEASURING DEVICES

There are many devices for measuring and indicating fluid pressure. Some devices measure gage pressure; others measure absolute pressure. The effects of nonstandard atmospheric pressure and nonstandard gravitational acceleration must be determined, particularly for devices relying on columns of liquid to indicate pressure. Table 15.1 lists the common types of devices and the ranges of pressure appropriate for each.

Table 15.1 *Common Pressure-Measuring Devices*

device	approximate range (in atm)
water manometer	0–0.1
mercury barometer	0–1
mercury manometer	0.001–1
metallic diaphragm	0.01–200
transducer	0.001–700
Bourdon pressure gauge	1–3000
Bourdon vacuum gauge	0.1–1

The *Bourdon pressure gauge* is the most common pressure-indicating device. This mechanical device consists of a coiled hollow tube that tends to straighten out (i.e., unwind) when the tube is subjected to an internal pressure. The degree to which the coiled tube unwinds depends on the difference between the internal and external pressures. A Bourdon gauge directly indicates *gage pressure.* Extreme accuracy is generally not a characteristic of Bourdon gauges.

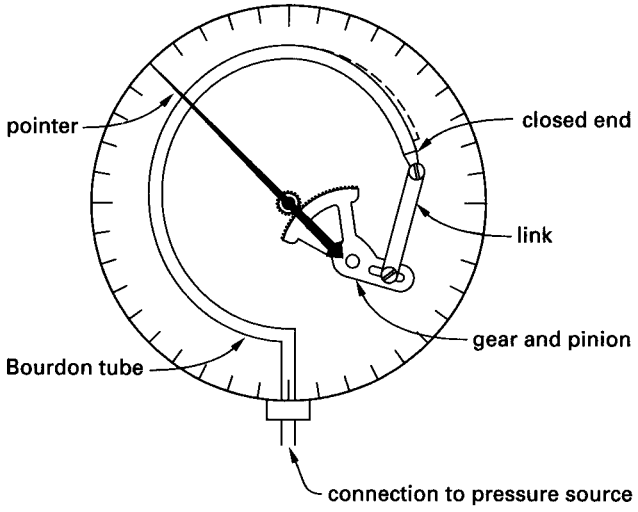

Figure 15.1 *C-Bourdon Pressure Gauge*

In non-SI installations, gauges are always calibrated in psi, unless the dial is marked "altitude" (measuring in feet of water) or "vacuum" (measuring in inches of mercury) on its face. To avoid confusion, the gauge dial will be clearly marked if other units are indicated.

The *barometer* is a common device for measuring the absolute pressure of the atmosphere.[1] It is constructed by filling a long tube open at one end with mercury (or alcohol, or some other liquid) and inverting the tube so that the open end is below the level of a mercury-filled container. If the vapor pressure of the mercury in the tube is neglected, the fluid column will be supported only by the atmospheric pressure transmitted through the container fluid at the lower, open end.

[1]A barometer can be used to measure the pressure inside any vessel. However, the barometer must be completely enclosed in the vessel, which may not be possible. Also, it is difficult to read a barometer enclosed within a tank.

Strain gages, diaphragm gauges, quartz-crystal transducers and other devices using the *piezoelectric effect* are also used to measure stress and pressure, particularly when pressure fluctuates quickly (e.g., as in a rocket combustion chamber). With these devices, calibration is required to interpret pressure from voltage generation or changes in resistance, capacitance, or inductance. These devices are generally unaffected by atmospheric pressure or gravitational acceleration.

Manometers (U-tube manometers) can also be used to indicate small pressure differences, and for this purpose they provide great accuracy. (Manometers are not suitable for measuring pressures much larger than 10 psi (70 kPa), however.) A difference in manometer fluid surface heights is converted into a pressure difference. If one end of a manometer is open to the atmosphere, the manometer indicates gage pressure. It is theoretically possible, but impractical, to have a manometer indicate absolute pressure, since one end of the manometer would have to be exposed to a perfect vacuum.

A *static pressure tube (piezometer tube)* is a variation of the manometer. It is a simple method of determining the static pressure in a pipe or other vessel, regardless of fluid motion in the pipe. A vertical transparent tube is connected to a hole in the pipe wall.[2] (None of the tube projects into the pipe.) The static pressure will force the contents of the pipe up into the tube. The height of the contents will be an indication of gage pressure in the pipe.

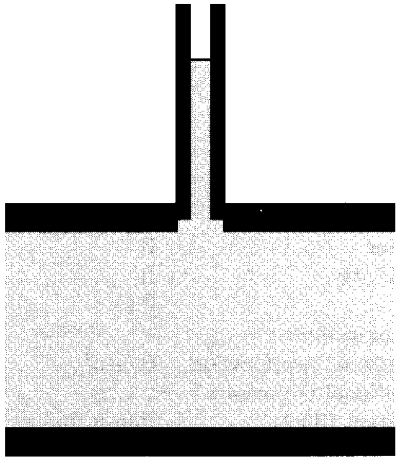

Figure 15.2 *Static Pressure Tube*

The device used to measure the pressure should not be confused with the method used to obtain exposure to the pressure. For example, a static pressure *tap* in a pipe is merely a hole in the pipe wall. A Bourdon gauge, manometer, or transducer can then be used with the tap to indicate pressure.

[2]Where greater accuracy is required, multiple holes may be drilled around the circumference of the pipe and connected through a manifold (*piezometer ring*) to the pressure-measuring device.

Tap holes are generally 1/8 to 1/4 in in diameter, drilled at right angles to the wall, and smooth and flush with the pipe wall. No part of the gauge or connection projects into the pipe. The tap holes should be at least 5 to 10 pipe diameters downstream from any source of turbulence (e.g., a bend, fitting, or valve).

2. MANOMETERS

Figure 15.3 illustrates a simple U-tube manometer used to measure the difference in pressure between two vessels. When both ends of the manometer are connected to pressure sources, the name *differential manometer* is used. If one end of the manometer is open to the atmosphere, the name *open manometer* is used.[3] The open manometer implicitly measures gage pressures.

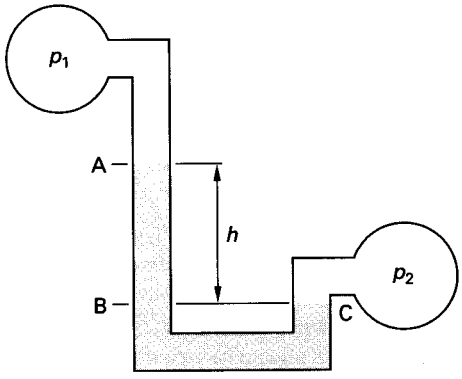

Figure 15.3 *Simple U-Tube Manometer*

Since the pressure at point B in Fig. 15.3 is the same as at point C, the pressure differential produces the vertical fluid column of height h. In Eq. 15.2, A is the area of the tube. Equations 15.2 and 15.3 assume consistent density units. In the absence of any capillary action, the inside diameters of the manometer tubes are irrelevant.

$$F_{\text{net}} = \text{weight of fluid column} \qquad 15.1$$

$$(p_2 - p_1) \times A = \rho_m g h \times A \qquad 15.2$$

$$p_2 - p_1 = \rho_m g h \qquad \text{[SI]} \qquad 15.3$$

In countries that do not use SI units, densities are commonly quoted in pounds per cubic foot. In that case, Eq. 15.3 can be written as

$$p_2 - p_1 = \rho_m \times \frac{g}{g_c} \times h$$

$$= \gamma_m h \qquad \text{[U.S.]} \qquad 15.4$$

The quantity g/g_c has a value of 1.0 lbf/lbm in almost all cases, and thus γ_m is numerically equal to ρ_m with units of lbf/ft^3.

[3]If one of the manometer legs is inclined, the term *inclined manometer* or *draft gauge* is used. Although only the vertical distance between the manometer fluid surfaces should be used to calculate the pressure difference, with small pressure differences it may be more accurate to read the inclined distance (which is larger than the vertical distance) and compute the vertical distance from the angle of inclination.

Equations 15.3 and 15.4 assume that the manometer fluid height is small, or that only low-density gases fill the tubes above the manometer fluid. If a high-density fluid (such as water) is present above the measuring fluid, or if the columns h_1 or h_2 are very long, corrections will be necessary.

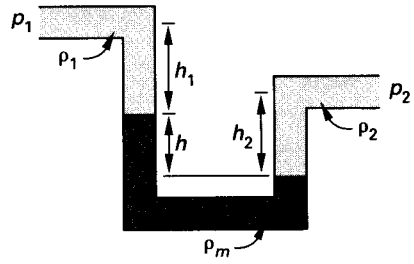

Figure 15.4 *Manometer Requiring Corrections*

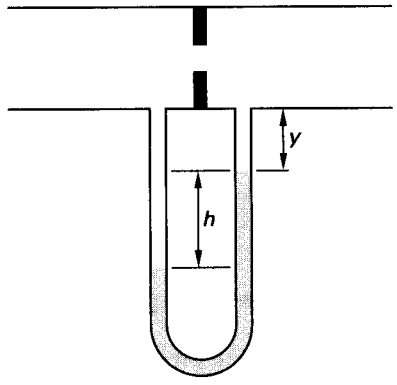
Fluid column h_2 "sits on top" of the manometer fluid, forcing the manometer fluid to the left. This increase must be subtracted out. Similarly, the column h_1 restricts the movement of the manometer fluid. The observed measurement must be increased to correct for this restriction.

$$p_2 - p_1 = g(\rho_m h + \rho_1 h_1 - \rho_2 h_2) \qquad \text{[SI]} \qquad 15.5(a)$$

$$p_2 - p_1 = \frac{g}{g_c} \times (\rho_m h + \rho_1 h_1 - \rho_2 h_2)$$

$$= \gamma_m h + \gamma_1 h_1 - \gamma_2 h_2 \qquad \text{[U.S.]} \qquad 15.5(b)$$

When a manometer is used to measure the pressure difference across an orifice or other fitting (as in Fig. 15.5), it is not necessary to correct the manometer reading for all of the liquid present above the manometer fluid. This is because parts of the correction for both sides of the manometer are the same. Thus, the distance y in Fig. 15.5 is an irrelevant distance.



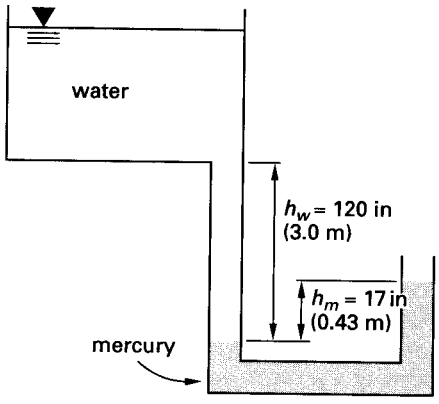


Figure 15.5 *Irrelevant Distance*

Manometer tubes are generally large enough in diameter to avoid significant capillary effects. Corrections for capillarity are seldom necessary.

Example 15.1

The pressure at the bottom of a tank of water (62.4 lbm/ft^3; ρ = 998 kg/m^3) is measured with a mercury manometer. (The density of mercury is 848 lbm/ft^3; 13 575 kg/m^3.) What is the gage pressure at the bottom of the water tank?

SI Solution

From Eq. 15.5(a),

$$\begin{aligned}\Delta p &= g(\rho_m h_m - \rho_w h_w) \\ &= \left(9.81\ \frac{\text{m}}{\text{s}^2}\right)\left[\left(13\,575\ \frac{\text{kg}}{\text{m}^3}\right)(0.43\ \text{m}) \right. \\ &\quad \left. - \left(998\ \frac{\text{kg}}{\text{m}^3}\right)(3.0\ \text{m})\right] \\ &= 27\,892\ \text{Pa (27.9 kPa gage)}\end{aligned}$$

Customary U.S. Solution

From Eq. 15.5(b),

$$\begin{aligned}\Delta p &= \gamma_m h_m - \gamma_w h_w \\ &= \frac{\left(848\ \frac{\text{lbf}}{\text{ft}^3}\right)(17\ \text{in}) - \left(62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(120\ \text{in})}{\left(12\ \frac{\text{in}}{\text{ft}}\right)^3} \\ &= 4.01\ \text{lbf/in}^2\ \text{(psig)}\end{aligned}$$

3. HYDROSTATIC PRESSURE

Hydrostatic pressure is the pressure a fluid exerts on an immersed object or container walls.[4] Pressure is equal to the force per unit area of surface.

$$p = \frac{F}{A} \qquad 15.6$$

[4]The term *hydrostatic* is used with all fluids, not only with water.

Hydrostatic pressure in a stationary, incompressible fluid behaves according to the following characteristics.

- Pressure is a function of vertical depth (and density) only. The pressure will be the same at two points with identical depths.
- Pressure varies linearly with (vertical) depth.
- Pressure is independent of an object's area and size and the weight (mass) of water above the object. Figure 15.6 illustrates the *hydrostatic paradox*. The pressures at depth h are the same in all four columns because pressure depends on depth, not volume.

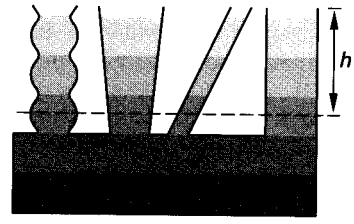

Figure 15.6 Hydrostatic Paradox

- Pressure at a point has the same magnitude in all directions (*Pascal's law*). Thus, pressure is a scalar quantity.
- Pressure is always normal to a surface, regardless of the surface's shape or orientation. (This is a result of the fluid's inability to support shear stress.)
- The resultant of the pressure distribution acts through the *center of pressure*.

4. FLUID HEIGHT EQUIVALENT TO PRESSURE

Pressure varies linearly with depth. The relationship between pressure and depth (i.e., the *hydrostatic head*) for an incompressible fluid is given by Eq. 15.7.

$$p = \rho g h \qquad \text{[SI]} \qquad 15.7(a)$$

$$p = \frac{\rho g h}{g_c} = \gamma h \qquad \text{[U.S.]} \qquad 15.7(b)$$

Since ρ and g are constants, Eq. 15.7 shows that p and h are linearly related. Knowing one determines the other.[5] For example, the height of a fluid column needed to produce a pressure is

$$h = \frac{p}{\rho g} \qquad \text{[SI]} \qquad 15.8(a)$$

$$h = \frac{p g_c}{\rho g} = \frac{p}{\gamma} \qquad \text{[U.S.]} \qquad 15.8(b)$$

[5]In fact, pressure and height of a fluid column can be used interchangeably. The height of a fluid column is known as *head*. For example: "The fan developed a static head of 3 inches of water," or "The pressure head at the base of the water tank was 8 meters." When the term "head" is used, it is essential to specify the fluid.

Table 15.2 lists six important fluid height equivalents that many engineers commit to memory.[6]

Table 15.2 *Approximate Fluid Height Equivalents at 68°F (20°C)*

liquid	height equivalents
water	0.0361 psi/in
water	62.4 psf/ft
water	9.81 kPa/m
water	2.31 ft/psi
mercury	0.491 psi/in
mercury	133.4 kPa/m

A barometer is an example of the measurement of pressure by the height of a fluid column. If the vapor pressure of the barometer liquid is neglected, the atmospheric pressure will be given by Eq. 15.9.

$$p_a = \rho g h \qquad \text{[SI]} \qquad 15.9(a)$$

$$p_a = \frac{\rho g h}{g_c} = \gamma h \qquad \text{[U.S.]} \qquad 15.9(b)$$

If the vapor pressure of the barometer liquid is significant (as it would be with alcohol or water), the vapor pressure effectively reduces the height of the fluid column, as Eq. 15.10 illustrates.

$$p_a - p_v = \rho g h \qquad \text{[SI]} \qquad 15.10(a)$$

$$p_a - p_v = \frac{\rho g h}{g_c} = \gamma h \qquad \text{[U.S.]} \qquad 15.10(b)$$

Example 15.2

A vacuum pump is used to drain a flooded mine shaft of 68°F (20°C) water.[7] The vapor pressure of water at this temperature is 0.34 psi (2.34 kPa). The pump is incapable of lifting the water higher than 400 in (10.16 m). What is the atmospheric pressure?

SI Solution

From Eq. 15.10,

$$\begin{aligned} p_a &= p_v + \rho g h \\ &= 2.34 \text{ kPa} + \frac{\left(998 \frac{\text{kg}}{\text{m}^3}\right)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(10.16 \text{ m})}{1000 \frac{\text{Pa}}{\text{kPa}}} \\ &= 101.8 \text{ kPa} \end{aligned}$$

(alternate SI solution, using Table 15.2)

$$\begin{aligned} p_a &= p_v + \rho g h \\ &= 2.34 \text{ kPa} + \left(9.8 \frac{\text{kPa}}{\text{m}}\right)(10.16 \text{ m}) \\ &= 101.9 \text{ kPa} \end{aligned}$$

Customary U.S. Solution

From Table 15.2, the height equivalent of water is approximately 0.0361 psi/in. Notice that psi/in is the same as lbf/in^3, the units of γ. From Eq. 15.10, the atmospheric pressure is

$$\begin{aligned} p_a &= p_v + \rho g h = \rho_v + \gamma h \\ &= 0.34 \frac{\text{lbf}}{\text{in}^2} + \left(0.0361 \frac{\text{lbf}}{\text{in}^3}\right)(400 \text{ in}) \\ &= 14.78 \text{ lbf/in}^2 \text{ (psia)} \end{aligned}$$

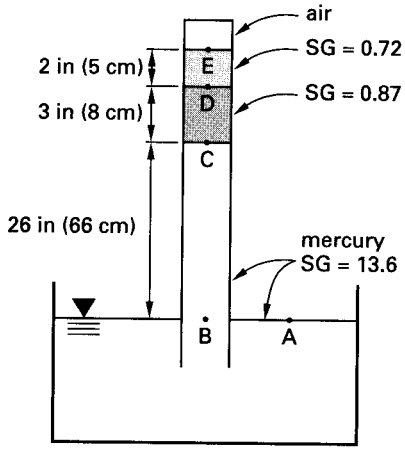
5. MULTIFLUID BAROMETERS

It is theoretically possible to fill a barometer tube with several different immiscible fluids.[8] Upon inversion, the fluids will separate, leaving the most dense fluid at the bottom and the least dense fluid at the top. All of the fluids will contribute, by superposition, to the balance between the external atmospheric pressure and the weight of the fluid column.

$$p_a - p_v = g \sum \rho_i h_i \qquad \text{[SI]} \qquad 15.11(a)$$

$$p_a - p_v = \frac{g}{g_c} \sum \rho_i h_i = \sum \gamma_i h_i \qquad \text{[U.S.]} \qquad 15.11(b)$$

The pressure at any intermediate point within the fluid column is found by starting at a location where the pressure is known, and then adding or subtracting $\rho g h$ to get to the point where the pressure is needed. Usually, the known pressure will be the atmospheric pressure located in the barometer barrel at the level (elevation) of the fluid outside of the barometer.



Example 15.3

Neglecting vapor pressure, what is the pressure of the air (at point E) in the container shown? The external pressure is 1.0 atm.

[6] Of course, these values are recognized to be the approximate specific weights of the liquids.

[7] A reciprocating or other direct-displacement pump would be a better choice to drain a mine.

[8] In practice, barometers are never constructed this way. This theory is more applicable to a category of problems dealing with up-ended containers, as illustrated in Ex. 15.3.

SI Solution

$$p_E = p_{\text{atm}} - g\rho_{\text{water}} \sum (\text{SG}_i)h_i$$

$$= 101\,300 \text{ Pa} - \left(9.81 \frac{\text{m}}{\text{s}^2}\right)\left(1000 \frac{\text{kg}}{\text{m}^3}\right)$$
$$\times [(0.66 \text{ m})(13.6) + (0.08 \text{ m})(0.87)$$
$$+ (0.05 \text{ m})(0.72)]$$
$$= 12\,210 \text{ Pa (12.2 kPa)}$$

Customary U.S. Solution

The pressure at point B is the same as the pressure at point A—1.0 atm. The density of mercury is $13.6 \times 0.0361 = 0.491$ lbm/in^3. The pressure at point C is

$$p_C = 14.7 \text{ psia} - (26 \text{ in})\left(0.491 \frac{\frac{\text{lbf}}{\text{in}^2}}{\text{in}}\right)$$
$$= 1.93 \text{ lbf/in}^2 \text{ (psia)}$$

Similarly, the pressure at point E (and anywhere within the captive air) is

$$p_E = 14.7 \frac{\text{lbf}}{\text{in}^2} - (26 \text{ in})\left(0.491 \frac{\text{lbf}}{\text{in}^3}\right)$$
$$- (3 \text{ in})(0.87)\left(0.0361 \frac{\text{lbf}}{\text{in}^3}\right)$$
$$- (2 \text{ in})(0.72)\left(0.0361 \frac{\text{lbf}}{\text{in}^3}\right)$$
$$= 1.79 \text{ lbf/in}^2 \text{ (psia)}$$

6. PRESSURE ON A HORIZONTAL PLANE SURFACE

The pressure on a horizontal plane surface is uniform over the surface because the depth of the fluid is uniform. The resultant of the pressure distribution acts through the center of pressure of the surface, which corresponds to the centroid of the surface.

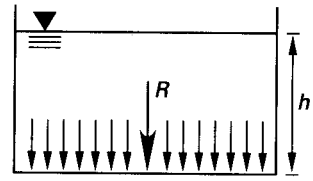


Figure 15.7 *Hydrostatic Pressure on a Horizontal Plane Surface*

The uniform pressure at depth h is given by Eq. 15.12.[9]

$$p = \rho g h \quad \text{[SI]} \qquad 15.12(a)$$

$$p = \frac{\rho g h}{g_c} = \gamma h \quad \text{[U.S.]} \qquad 15.12(b)$$

The total vertical force on the horizontal plane of area A is given by Eq. 15.13.

$$R = pA \qquad 15.13$$

It is tempting, but not always correct, to calculate the vertical force on a submerged surface as the weight of the fluid above it. Such an approach works only when there is no change in the cross-sectional area of the fluid above the surface. This is a direct result of the *hydrostatic paradox*. Figure 15.8 illustrates two containers with the same pressure distribution (force) on their bottom surfaces.

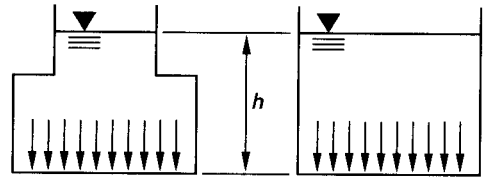

Figure 15.8 *Two Containers with the Same Pressure Distribution*

7. PRESSURE ON A VERTICAL PLANE SURFACE

The pressure on a vertical rectangular plane surface increases linearly with depth. The pressure distribution will be triangular, as in Fig. 15.9(a), if the plane surface extends to the surface; otherwise, the distribution will be trapezoidal, as in Fig. 15.9(b).

[9]The phrase *pressure at a depth* is universally understood to mean the *gage pressure*, as given by Eq. 15.12.

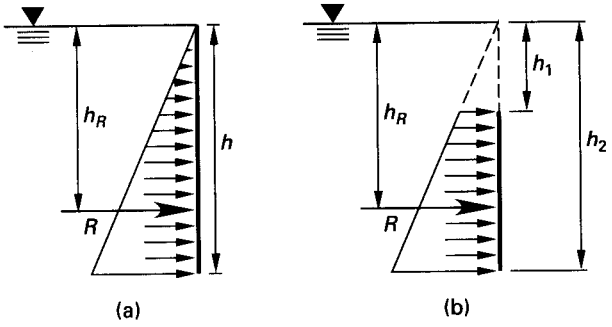

Figure 15.9 *Hydrostatic Pressure on a Vertical Plane Surface*

The resultant force is calculated from the *average pressure.*

$$\overline{p} = \tfrac{1}{2}(p_1 + p_2) \qquad 15.14$$

$$= \tfrac{1}{2}\rho g(h_1 + h_2) \quad \text{[SI]} \qquad 15.15(a)$$

$$\overline{p} = \frac{\frac{1}{2}\rho g(h_1 + h_2)}{g_c} = \tfrac{1}{2}\gamma(h_1 + h_2) \quad \text{[U.S.]} \qquad 15.15(b)$$

$$R = \overline{p}A \qquad 15.16$$

Although the resultant is calculated from the average depth, the resultant does not act at the average depth. The resultant of the pressure distribution passes through the centroid of the pressure distribution. For the triangular distribution of Fig. 15.9(a), the resultant is located at a depth of $h_R = {}^2/_3 h$. For the more general case of Fig. 15.9(b), the resultant is located from Eq. 15.17.

$$h_R = \tfrac{2}{3}\left(h_1 + h_2 - \frac{h_1 h_2}{h_1 + h_2}\right) \qquad 15.17$$

8. PRESSURE ON AN INCLINED PLANE SURFACE

The average pressure and resultant force on an inclined rectangular plane surface are calculated in much the same fashion as for the vertical plane surface. The pressure varies linearly with depth. The resultant is calculated from the average pressure, which, in turn, depends on the average depth.

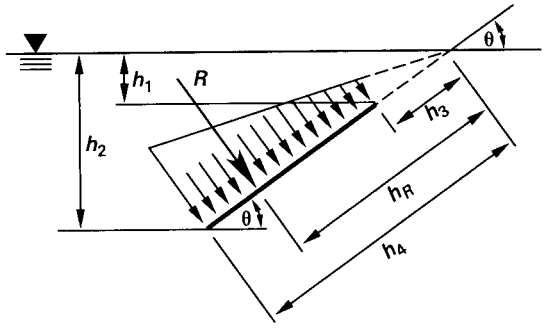

Figure 15.10 *Hydrostatic Pressure on an Inclined Rectangular Plane Surface*

The average pressure and resultant are given by Eqs. 15.18 through 15.21.

$$\overline{p} = \tfrac{1}{2}(p_1 + p_2) \qquad 15.18$$

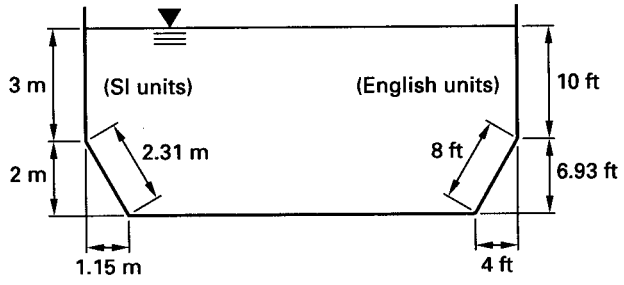
$$\overline{p} = \tfrac{1}{2}\rho g(h_1 + h_2) \qquad 15.19$$

$$\overline{p} = \tfrac{1}{2}\rho g(h_3 + h_4)\sin\theta \quad \text{[SI]} \qquad 15.20(a)$$

$$\overline{p} = \frac{\frac{1}{2}\rho g\,(h_1 + h_2)}{g_c} = \frac{\frac{1}{2}\rho g(h_3 + h_4)\sin\theta}{g_c}$$

$$= \tfrac{1}{2}\gamma(h_1 + h_2) = \tfrac{1}{2}\gamma(h_3 + h_4)\sin\theta \quad \text{[U.S.]} \qquad 15.20(b)$$

$$R = \overline{p}A \qquad 15.21$$



As with the vertical plane surface, the resultant acts at the centroid of the pressure distribution, not at the average depth. Equation 15.17 is rewritten in terms of inclined depths.[10]

$$h_R = \left(\frac{\frac{2}{3}}{\sin\theta}\right)\left(h_1 + h_2 - \frac{h_1 h_2}{h_1 + h_2}\right) \qquad 15.22$$

$$h_R = \left(\tfrac{2}{3}\right)\left(h_3 + h_4 - \frac{h_3 h_4}{h_3 + h_4}\right) \qquad 15.23$$

Example 15.4

The tank shown is filled with water ($\rho = 62.4$ lbm/ft^3; $\rho = 1000$ kg/m^3). (a) What is the force on a 1 ft (1 m) length of the inclined portion of the wall?[11] (b) At what depth (vertical distance) is the resultant located?

[10]Notice that h_R is an inclined distance. If a vertical distance is wanted, it must usually be calculated from h_R and $\sin\theta$. Equation 15.22 can be derived simply by dividing Eq. 15.17 by $\sin\theta$.

[11]Since the width of the tank (the distance into and out of the illustration) is unknown, it is common to calculate the pressure or force per unit width of tank wall. This is the same as calculating the pressure on a 1 ft (1 m) wide section of wall.

SI Solution

(a) The depth of the tank bottom is

$$h_2 = 3\text{ m} + 2\text{ m} = 5\text{ m}$$

From Eq. 15.19, the average pressure on the inclined section is

$$\begin{aligned}\overline{p} &= \left(\tfrac{1}{2}\right)\left(1000\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(3\text{ m} + 5\text{ m}) \\ &= 39\,240\text{ Pa} \quad \text{(gage)}\end{aligned}$$

The total force on a 1 m section of wall is

$$\begin{aligned}R &= \overline{p}A = (39\,240\text{ Pa})(2.31\text{ m})(1\text{ m}) \\ &= 90\,644\text{ N (90.6 kN)}\end{aligned}$$

(b) θ must be known to determine h_R.

$$\theta = \arctan\left(\frac{2\text{ m}}{1.15\text{ m}}\right) = 60^\circ$$

The location of the resultant can be calculated from Eq. 15.23 once h_3 and h_4 are known.

$$h_3 = \frac{3\text{ m}}{\sin 60^\circ} = 3.464\text{ m}$$

$$h_4 = \frac{5\text{ m}}{\sin 60^\circ} = 5.774\text{ m}$$

$$\begin{aligned}h_R &= \left(\tfrac{2}{3}\right)\left(3.464 + 5.774 - \frac{(3.464)(5.774)}{3.464 + 5.774}\right) \\ &= 4.715\text{ m} \quad \text{[inclined]}\end{aligned}$$

The vertical depth at which the resultant acts is

$$\begin{aligned}h &= h_R \sin\theta = (4.715\text{ m})(\sin 60^\circ) \\ &= 4.08\text{ m} \quad \text{[vertical]}\end{aligned}$$

Customary U.S. Solution

(a) The water density is given in traditional U.S. mass units. The specific weight, γ, is

$$\begin{aligned}\gamma = \frac{\rho g}{g_c} &= \frac{\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} \\ &= 62.4\text{ lbf/ft}^3\end{aligned}$$

The depth of the tank bottom is

$$h_2 = 10\text{ ft} + 6.93\text{ ft} = 16.93\text{ ft}$$

From Eq. 15.19, the average pressure on the inclined section is

$$\begin{aligned}\overline{p} &= \left(\tfrac{1}{2}\right)\left(62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(10\text{ ft} + 16.93\text{ ft}) \\ &= 840.2\text{ lbf/ft}^2\text{ (psfg)}\end{aligned}$$

The total force on a 1 ft section of wall is

$$\begin{aligned}R = \overline{p}A &= \left(840.2\ \frac{\text{lbf}}{\text{ft}^2}\right)(8\text{ ft})(1\text{ ft}) \\ &= 6722\text{ lbf}\end{aligned}$$

(b) θ must be known to determine h_R.

$$\theta = \arctan\left(\frac{6.93\text{ ft}}{4\text{ ft}}\right) = 60^\circ$$

The location of the resultant can be calculated from Eq. 15.23 once h_3 and h_4 are known.

$$h_3 = \frac{10\text{ ft}}{\sin 60^\circ} = 11.55\text{ ft}$$

$$h_4 = \frac{16.93\text{ ft}}{\sin 60^\circ} = 19.55\text{ ft}$$

From Eq. 15.23,

$$\begin{aligned}h_R &= \left(\tfrac{2}{3}\right)\left(11.55 + 19.55 - \frac{(11.55)(19.55)}{11.55 + 19.55}\right) \\ &= 15.89\text{ ft} \quad \text{[inclined]}\end{aligned}$$

The vertical depth at which the resultant acts is

$$\begin{aligned}h &= h_R \sin\theta = (15.89\text{ ft})(\sin 60^\circ) \\ &= 13.76\text{ ft} \quad \text{[vertical]}\end{aligned}$$

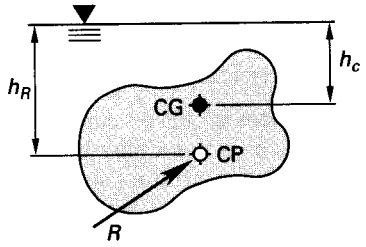
9. PRESSURE ON A GENERAL PLANE SURFACE

Figure 15.11 illustrates a nonrectangular plane surface that may or may not extend to the liquid surface and that may or may not be inclined. As with other regular surfaces, the resultant force depends on the average pressure and acts through the center of pressure (CP). The average pressure is calculated from the depth of the surface's centroid (CG).

$$\overline{p} = \rho g h_c \sin\theta \quad \text{[SI]} \qquad 15.24(a)$$

$$\overline{p} = \frac{\rho g h_c \sin\theta}{g_c} = \gamma h_c \sin\theta \quad \text{[U.S.]} \qquad 15.24(b)$$

$$R = \overline{p}A \qquad 15.25$$



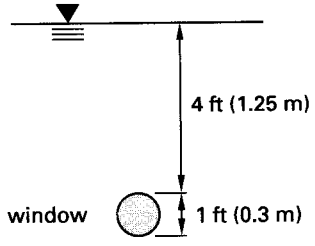


Figure 15.11 *General Plane Surface*

The resultant force acts at depth h_R normal to the plane surface. I_c in Eq. 15.26 is the centroidal area moment of inertia, with dimensions of L^4 (length^4) about an axis parallel to the surface. (Appendix 42.A contains equations for the moment of inertia of common shapes.) Both h_c and h_R are measured parallel to the plane surface. That is, if the plane surface is inclined, h_c and h_R are inclined distances.

$$h_R = h_c + \frac{I_c}{A\,h_c} \qquad 15.26$$

Example 15.5

The top edge of a vertical circular observation window in a submarine is located 4.0 ft (1.25 m) below the surface of the water. The window is 1.0 ft (0.3 m) in diameter. The density of the water is 62.4 lbm/ft^3 (1000 kg/m^3). Neglect the salinity of the water. (a) What is the resultant force on the window? (b) At what depth does the resultant force act?

SI Solution

(a) The radius of the window is

$$r = \frac{0.3\text{ m}}{2} = 0.15\text{ m}$$

$$h_c = 1.25\text{ m} + 0.15\text{ m} = 1.4\text{ m}$$

$$A = \pi(0.15\text{ m})^2 = 0.0707\text{ m}^2$$

$$\overline{p} = \left(1000\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(1.4\text{ m})$$

$$= 13\,734\text{ Pa (gage)}$$

$$R = (13\,734\text{ Pa})(0.0707\text{ m}^2) = 971\text{ N}$$

(b) $$I_c = \left(\frac{\pi}{4}\right)(0.15\text{ m})^4 = 3.976 \times 10^{-4}\text{ m}^4$$

$$h_R = 1.4\text{ m} + \frac{3.976 \times 10^{-4}\text{ m}^4}{(0.0707\text{ m}^2)(1.4\text{ m})}$$

$$= 1.404\text{ m}$$

Customary U.S. Solution

(a) The radius of the window is

$$r = \frac{1\text{ ft}}{2} = 0.5\text{ ft}$$

The depth at which the centroid of the circular window is located is

$$h_c = 4.0\text{ ft} + 0.5\text{ ft} = 4.5\text{ ft}$$

The area of the circular window is

$$A = \pi r^2 = \pi(0.5\text{ ft})^2$$

$$= 0.7854\text{ ft}^2$$

As in Ex. 15.4, the resultant force will be calculated using γ as the weight density.

The average pressure is

$$\overline{p} = \gamma h_c = \left(62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(4.5\text{ ft})$$

$$= 280.8\text{ lbf/ft}^2\text{ (psfg)}$$

The resultant is calculated from Eq. 15.21.

$$R = \overline{p}A = \left(280.8\ \frac{\text{lbf}}{\text{ft}^2}\right)(0.7854\text{ ft}^2)$$

$$= 220.5\text{ lbf}$$

(b) The centroidal area moment of inertia of a circle is

$$I_c = \frac{\pi}{4}r^4 = \left(\frac{\pi}{4}\right)(0.5\text{ ft})^4$$

$$= 0.049\text{ ft}^4$$

From Eq. 15.26, the depth at which the resultant force acts is

$$h_R = 4.5\text{ ft} + \frac{0.049\text{ ft}^4}{(0.7854\text{ ft}^2)(4.5\text{ ft})}$$

$$= 4.514\text{ ft}$$

10. SPECIAL CASES: VERTICAL SURFACES

Several simple wall shapes and configurations recur frequently. Figure 15.12 indicates the location of their hydrostatic pressure resultants (*centers of pressure*). In

all cases, the surfaces are vertical and extend to the liquid's surface.

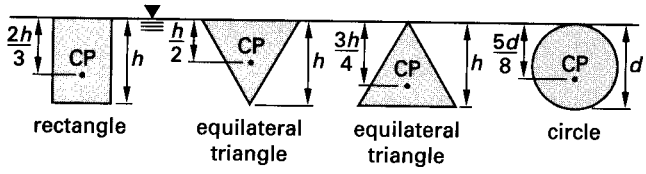

Figure 15.12 *Centers of Pressure for Common Configurations*

11. FORCES ON CURVED AND COMPOUND SURFACES

Figure 15.13 illustrates a curved surface. The resultant force acting on such a curved surface is not difficult to determine, although the x- and y-components of the resultant usually must be calculated first. The magnitude and direction of the resultant are found by conventional methods.

$$R = \sqrt{R_x^2 + R_y^2} \qquad 15.27$$

$$\theta = \arctan\left(\frac{R_y}{R_x}\right) \qquad 15.28$$

The horizontal component of the resultant hydrostatic force is found in the same manner as for a vertical plane surface.

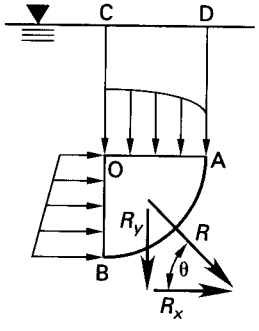

Figure 15.13 *Pressure Distributions on a Curved Surface*

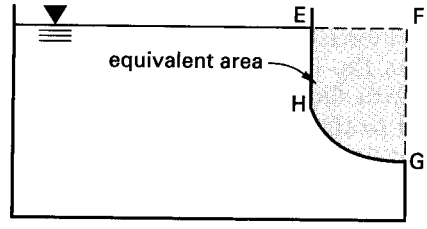
The fact that the surface is curved does not affect the calculation of the horizontal force. In Fig. 15.13, the horizontal pressure distribution on curved surface BA is the same as the horizontal pressure distribution on imaginary projected surface BO.

The vertical component of force on the curved surface is most easily calculated as the weight of the liquid above it.[12] In Fig. 15.13, the vertical component of force on the curved surface BA is the weight of liquid within the area ABCD, with a vertical line of action passing through the centroid of the area ABCD.

Figure 15.14 illustrates a curved surface with no liquid above it. However, it is not difficult to show that the resultant force acting upward on the curved surface HG is equal in magnitude (and opposite in direction) to the force that would be acting downward due to the missing area EFGH. Such an imaginary area used to calculate hydrostatic pressure is known as an *equivalent area.*



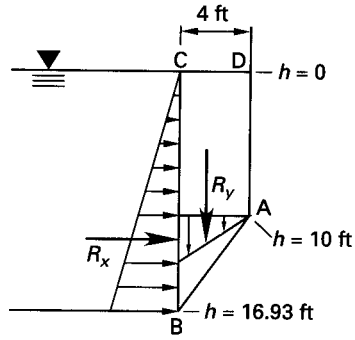


Figure 15.14 *Equivalent Area*

Example 15.6

What is the total force on a 1 ft section of the wall in Ex. 15.4?

Solution

The average depth is

$$\overline{h} = \left(\tfrac{1}{2}\right)(0 + 16.93 \text{ ft}) = 8.465 \text{ ft}$$

The average pressure and horizontal component of the resultant on a 1 ft section of wall are

$$\overline{p} = \gamma\overline{h} = \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)(8.465 \text{ ft})$$

$$= 528.2 \text{ lbf/ft}^2 \text{ (psfg)}$$

$$R_x = \overline{p}A = \left(528.2 \frac{\text{lbf}}{\text{ft}^2}\right)(16.93 \text{ ft})(1 \text{ ft})$$

$$= 8942 \text{ lbf}$$

The volume of a 1 ft section of area ABCD is

$$V_{ABCD} = (1 \text{ ft})\left[(4 \text{ ft})(10 \text{ ft}) + \left(\tfrac{1}{2}\right)(4 \text{ ft})(6.93 \text{ ft})\right]$$

$$= 53.86 \text{ ft}^3$$

[12] Calculating the vertical force component is not in conflict with the hydrostatic paradox as long as the cross-sectional area of liquid above the curved surface does not decrease between the curved surface and the liquid's free surface. If there is a change in the cross-sectional area, the vertical component of force is equal to the weight of fluid in an unchanged cross-sectional area (i.e., the equivalent area).

The vertical component is

$$R_y = \gamma V = \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)(53.86 \text{ ft}^3)$$
$$= 3361 \text{ lbf}$$

The total resultant force is

$$R = \sqrt{(8942 \text{ lbf})^2 + (3361 \text{ lbf})^2}$$
$$= 9553 \text{ lbf}$$

12. TORQUE ON A GATE

When an openable gate or door is submerged in such a manner as to have unequal depths of liquid on either of its sides, or when there is no liquid present on one side of a gate or door, the hydrostatic pressure will act to either open or close the door. If the gate does not open, this pressure is resisted, usually by a latching mechanism on the gate itself.[13] The magnitude of the resisting latch force can be determined from the *hydrostatic torque (hydrostatic moment)* acting on the gate. The moment is almost always taken with respect to the gate hinges.

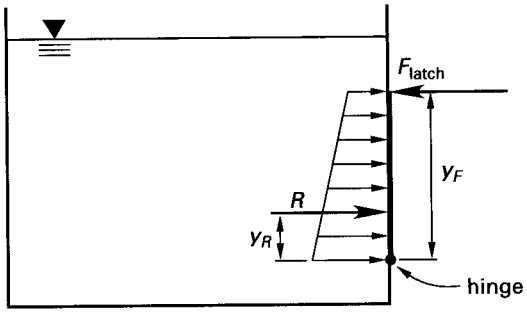

Figure 15.15 *Torque on a Hinge*

The applied moment is calculated as the product of the resultant force on the gate and the distance from the hinge to the resultant on the gate. This applied moment is balanced by the resisting moment, calculated as the latch force times the separation of the latch and hinge.

$$M_{\text{applied}} = M_{\text{resisting}} \qquad 15.29$$
$$R \times y_R = F_{\text{latch}} \times y_F \qquad 15.30$$

13. HYDROSTATIC FORCES ON A DAM

The techniques presented in the preceding sections are applicable to dams. That is, the horizontal force on the dam face can be found as in Ex. 15.6, regardless of inclination or curvature of the dam face. The vertical force on the dam face is calculated as the weight of the water above the dam face. Of course, the vertical force is zero if the dam face is vertical.

Figure 15.16 illustrates a typical dam, defining its *heel, toe,* and *crest.*

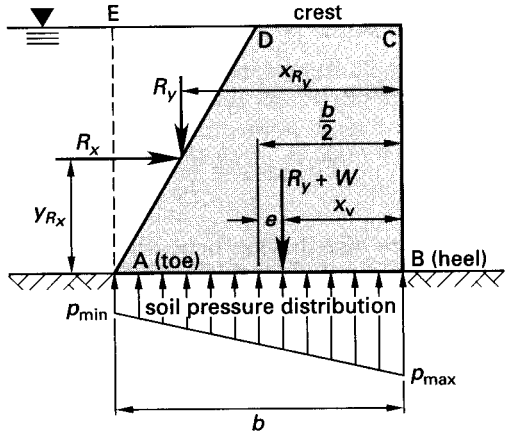

Figure 15.16 *Dam*

However, there are other considerations for gravity dams.[14] Most notably, the dam must not tip over or slide away due to the hydrostatic pressure. Furthermore, the pressure distribution within the soil under the dam is not uniform, and soil loading must not be excessive.

The *overturning moment* is a measure of the horizontal pressure's tendency to tip the dam over, pivoting it about the heel of the dam (point B in Fig. 15.16). (Usually, moments are calculated with respect to the pivot point.) The overturning moment is calculated as the product of the horizontal component of hydrostatic pressure (i.e., the x-component of the resultant) and the vertical distance between the heel and the line of action of the force.

$$M_{\text{overturning}} = R_x \times y_{R_x} \qquad 15.31$$

In most configurations, the overturning is resisted jointly by moments from the dam's own weight, W, and the vertical component of the resultant, R_y (i.e., the weight of area EAD in Fig. 15.16).[15]

$$M_{\text{resisting}} = (R_y \times x_{R_y}) + (W \times x_{\text{CG}}) \qquad 15.32$$

The *factor of safety against overturning* is

$$(\text{FS})_{\text{overturning}} = \frac{M_{\text{resisting}}}{M_{\text{overturning}}} \qquad 15.33$$

[13]Any contribution to resisting force from stiff hinges or other sources of friction is typically neglected.

[14]A *gravity dam* is one that is held in place and orientation by its own mass (weight) and the friction between its base and the ground.

[15]The density of concrete or masonry is usually taken to be approximately 150 lbm/ft^3 (2400 kg/m^3).

In addition to causing the dam to tip over, the horizontal component of hydrostatic force will also cause the dam to tend to slide along the ground. This tendency is resisted by the frictional force between the dam bottom and soil. The frictional force, F_f, is calculated as the product of the *normal force*, N, and the *coefficient of static friction*, μ.

$$F_f = \mu_{\text{static}}\, N = \mu_{\text{static}}(W + R_y) \qquad 15.34$$

The *factor of safety against sliding* is

$$(\text{FS})_{\text{sliding}} = \frac{F_f}{R_x} \qquad 15.35$$

The soil pressure distribution beneath the dam is usually assumed to vary linearly from a minimum to a maximum value. (The minimum value must be greater than zero, since soil cannot be in a state of tension. The maximum pressure should not exceed the allowable soil pressure.) Equation 15.36 predicts the minimum and maximum soil pressures.

$$p_{\max}, p_{\min} = \left(\frac{R_y + W}{b}\right)\left(1 \pm \frac{6e}{b}\right) \qquad 15.36$$

The *eccentricity*, e, in Eq. 15.36 is the distance between the mid-length of the dam and the line of action of the total vertical force, $W + R_y$. (The eccentricity must be less than $b/6$ for the entire base to be in compression.) Notice that distances x_{v} and x_{CG} are different.

$$e = \frac{b}{2} - x_{\text{v}} \qquad 15.37$$

$$x_{\text{v}} = \frac{M_{\text{resisting}}}{R_y + W} \qquad 15.38$$

14. PRESSURE DUE TO SEVERAL IMMISCIBLE LIQUIDS

Figure 15.17 illustrates the non-uniform pressure distribution due to two immiscible liquids (e.g., oil on top and water below).

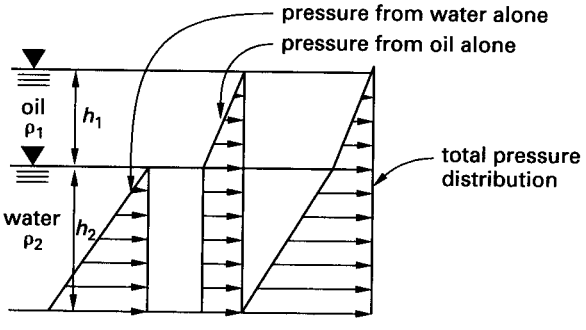

Figure 15.17 *Pressure Distribution from Two Immiscible Liquids*

The pressure due to the upper liquid (oil), once calculated, serves as a *surcharge* to the liquid below (water). The pressure at the tank bottom is given by Eq. 15.39. (The principle can be extended to three or more immiscible liquids as well.)

$$p_{\text{bottom}} = \rho_1 g h_1 + \rho_2 g h_2 \qquad \text{[SI]} \quad 15.39(a)$$

$$p_{\text{bottom}} = \frac{\rho_1 g h_1}{g_c} + \frac{\rho_2 g h_2}{g_c} = \gamma_1 h_1 + \gamma_2 h_2 \qquad \text{[U.S.]} \quad 15.39(b)$$

15. PRESSURE FROM COMPRESSIBLE FLUIDS

Fluid density, thus far, has been assumed to be independent of pressure. In reality, even "incompressible" liquids are slightly compressible. Sometimes, the effect of this compressibility cannot be neglected.

The familiar $p = \rho g h$ equation is a special case of Eq. 15.40. (It is assumed that $h_2 > h_1$. The minus sign in Eq. 15.40 indicates that pressure decreases as elevation (height) increases.)

$$\int_{p_1}^{p_2} \frac{dp}{\rho g} = -(h_2 - h_1) \qquad \text{[SI]} \quad 15.40(a)$$

$$\int_{p_1}^{p_2} \frac{g_c dp}{\rho g} = -(h_2 - h_1) \qquad \text{[U.S.]} \quad 15.40(b)$$

If the fluid is a perfect gas, and if compression is an isothermal (i.e., constant temperature) process, the relationship between pressure and density is given by Eq. 15.41. The isothermal assumption is appropriate, for example, for the earth's *stratosphere* (i.e., above 35,000 ft or 11 000 m), where the temperature is assumed to be constant at approximately −67°F (−55°C).

$$p\upsilon = \frac{p}{\rho} = RT = \text{constant} \qquad 15.41$$

In the isothermal case, Eq. 15.41 can be rewritten as Eq. 15.42. (For air, $R = 53.3$ ft-lbf/lbm-°R; $R = 286.7$ J/kg·K.) Of course, the temperature, T, must be in degrees absolute (i.e., in °R or K). Equation 15.42 is known as the *barometric height relationship*[16] because knowledge of atmospheric temperature and the pressures at two points is sufficient to determine the height difference between the two points.

$$h_2 - h_1 = \left(\frac{RT}{g}\right) \ln\left(\frac{p_1}{p_2}\right) \qquad \text{[SI]} \quad 15.42(a)$$

$$h_2 - h_1 = \left(\frac{g_c RT}{g}\right) \ln\left(\frac{p_1}{p_2}\right) \qquad \text{[U.S.]} \quad 15.42(b)$$

[16]You may recognize this as being equivalent to the work done in an isothermal compression process. The elevation (height) difference $h_2 - h_1$ (with units of feet) can be interpreted as the work done per unit mass during compression (with units of ft-lbf/lbm).

The pressure at an elevation (height) h_2 in a layer of perfect gas that has been isothermally compressed is given by Eq. 15.43.

$$p_2 = p_1 e^{\frac{g(h_1 - h_2)}{RT}} \quad \text{[SI]} \quad \textit{15.43(a)}$$

$$p_2 = p_1 e^{\frac{g(h_1 - h_2)}{g_c RT}} \quad \text{[U.S.]} \quad \textit{15.43(b)}$$

If the fluid is a perfect gas, and if compression is an *adiabatic process*, the relationship between pressure and density is given by Eq. 15.44.[17] k is the *ratio of specific heats*, a property of the gas. ($k = 1.4$ for air, hydrogen, oxygen, and carbon monoxide, among others.)

$$pv^k = p\left(\frac{1}{\rho}\right)^k = \text{constant} \quad \textit{15.44}$$

The following three equations apply to adiabatic compression of an ideal gas.

$$h_2 - h_1 = \left(\frac{k}{k-1}\right)\left(\frac{RT_1}{g}\right)\left[1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right] \quad \text{[SI]} \quad \textit{15.45(a)}$$

$$h_2 - h_1 = \left(\frac{k}{k-1}\right)\left(\frac{g_c}{g}\right)RT_1\left[1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right] \quad \text{[U.S.]} \quad \textit{15.45(b)}$$

$$p_2 = p_1\left[1 - \left(\frac{k-1}{k}\right)\left(\frac{g}{RT_1}\right)(h_2 - h_1)\right]^{\frac{k}{k-1}} \quad \text{[SI]} \quad \textit{15.46(a)}$$

$$p_2 = p_1\left[1 - \left(\frac{k-1}{k}\right)\left(\frac{g}{g_c}\right)\left(\frac{h_2 - h_1}{RT_1}\right)\right]^{\frac{k}{k-1}} \quad \text{[U.S.]} \quad \textit{15.46(b)}$$

$$T_2 = T_1\left[1 - \left(\frac{k-1}{k}\right)\left(\frac{g}{RT_1}\right)(h_2 - h_1)\right] \quad \text{[SI]} \quad \textit{15.47(a)}$$

$$T_2 = T_1\left[1 - \left(\frac{k-1}{k}\right)\left(\frac{g}{g_c}\right)\left(\frac{h_2 - h_1}{RT_1}\right)\right] \quad \text{[U.S.]} \quad \textit{15.47(b)}$$

The three adiabatic compression equations can be used for the more general *polytropic compression* case simply by substituting the *polytropic exponent*, n, for k.[18] Unlike the ratio of specific heats, the polytropic exponent is a function of the process, not the gas. The polytropic compression assumption is appropriate for the earth's *troposphere*.[19] Assuming a linear decrease in temperature with altitude of $-0.00356°\text{F/ft}$ ($-0.00649°\text{C/m}$), a polytropic exponent of $n = 1.235$ can be derived.

Example 15.7

The air pressure and temperature at sea level are 1.0 standard atmosphere and 68°F (20°C), respectively. Assume isentropic compression with $n = 1.235$. What is the pressure at an altitude of 5000 ft (1525 m)?

SI Solution

The absolute temperature of the air is $20°\text{C} + 273 = 293\text{K}$. From Eq. 15.46, the pressure at 1525 m altitude is

$$p_2 = (1.0\text{ atm})\left(1 - \left(\frac{1.235 - 1}{1.235}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right) \times \left[\frac{1525\text{ m}}{\left(286.7\ \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(293\text{K})}\right]\right)^{\frac{1.235}{1.235-1}}$$

$$= 0.834\text{ atm}$$

Customary U.S. Solution

The absolute temperature of the air is $68°\text{F} + 460 = 528°\text{R}$. From Eq. 15.46 (substituting $n = 1.235$ for polytropic compression), the pressure at 5000 ft altitude is

$$p_2 = (1.0\text{ atm})\left(1 - \left(\frac{1.235 - 1}{1.235}\right)\left(\frac{32.2\ \frac{\text{ft}}{\text{sec}^2}}{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}\right) \times \left[\frac{5000\text{ ft}}{\left(53.3\ \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(528°\text{R})}\right]\right)^{\frac{1.235}{1.235-1}}$$

$$= 0.835\text{ atm}$$

[17] There is no heat or energy transfer to or from the ideal gas in an adiabatic process. However, this is not the same as an isothermal process.

[18] Actually, polytropic compression is the general process. Isothermal compression is a special case ($n = 1$) of the polytropic process, as is adiabatic compression ($n = k$).

[19] The *troposphere* is the part of the earth's atmosphere we live in and where most atmospheric disturbances occur. The *stratosphere*, starting at approximately 35,000 ft (11 000 m), is cold, clear, dry, and still. Between the troposphere and the stratosphere is the *tropopause*, a transition layer that contains most of the atmosphere's dust and moisture. Temperature actually increases slightly in the tropopause.

16. EXTERNALLY PRESSURIZED LIQUIDS

If the gas above a liquid in a closed tank is pressurized to a gage pressure of p_t, this pressure will add to the hydrostatic pressure anywhere in the fluid. The pressure at the tank bottom illustrated in Fig. 15.18 is given by Eq. 15.48.

$$p_{\text{bottom}} = p_t + \rho gh \quad \text{[SI]} \qquad 15.48(a)$$

$$p_{\text{bottom}} = p_t + \frac{\rho gh}{g_c} = p_t + \gamma h \quad \text{[U.S.]} \qquad 15.48(b)$$

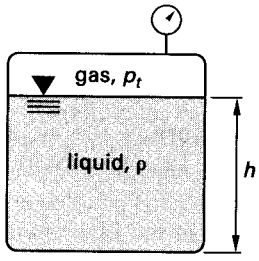

Figure 15.18 *Externally Pressurized Liquid*

17. HYDRAULIC RAM

A *hydraulic ram (hydraulic jack, hydraulic press, fluid press*, etc.) is illustrated in Fig. 15.19. This is a force-multiplying device. A force, F_p, is applied to the *plunger*, and a useful force, F_r, appears at the *ram*. Even though the pressure in the hydraulic fluid is the same everywhere, the forces at the two cylinders will be proportional to their respective cross-sectional areas.[20]

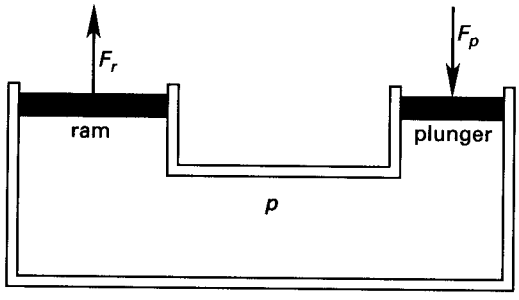

Figure 15.19 *Hydraulic Ram*

Since the pressure is the same everywhere, Eq. 15.49 can be solved for p for the ram and plunger.

$$F = pA = p\pi r^2 \qquad 15.49$$

$$p_p = p_r \qquad 15.50$$

$$\frac{F_p}{A_p} = \frac{F_r}{A_r} \qquad 15.51$$

$$\frac{F_p}{d_p^2} = \frac{F_r}{d_r^2} \qquad 15.52$$

[20] *Pascal's law*: Pressure in a liquid is the same in all directions.

Small, manually actuated hydraulic rams usually have a lever handle to increase the mechanical advantage of the ram from 1.0 to M, as illustrated in Fig. 15.20. In most cases, the pivot and connection mechanism will not be frictionless, and some of the applied force will be used to overcome the friction. This friction loss is accounted for by a *lever efficiency* or *lever effectiveness*, η.

$$M = \frac{L_1}{L_2} \qquad 15.53$$

$$F_p = \eta\, MF_l \qquad 15.54$$

$$\frac{\eta\, MF_l}{A_p} = \frac{F_r}{A_r} \qquad 15.55$$

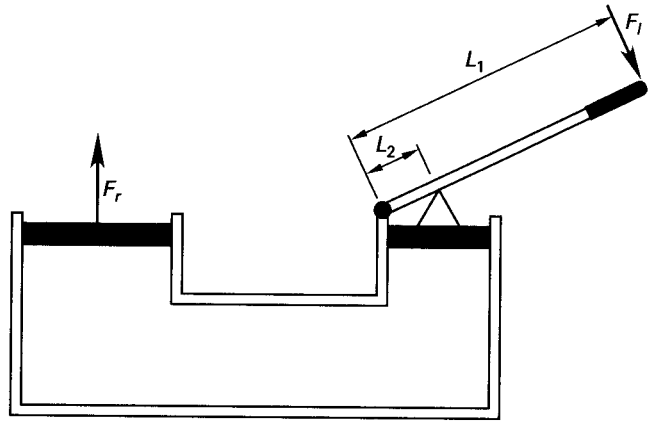

Figure 15.20 *Hydraulic Ram with Mechanical Advantage*

18. BUOYANCY

Buoyant force is an upward force that acts on all objects that are partially or completely submerged in a fluid. The fluid can be a liquid, as in the case of a ship floating at sea, or the fluid can be a gas, as in a balloon floating in the atmosphere.

There is a buoyant force on all submerged objects, not just those that are stationary or ascending. There will be, for example, a buoyant force on a rock sitting at the bottom of a pond. There will also be a buoyant force on a rock sitting exposed on the ground, since the rock is "submerged" in air. A buoyant force due to displaced air also exists, although it may be insignificant, in the case of partially exposed floating objects such as icebergs.

Buoyant force always acts to counteract an object's weight (i.e., buoyancy acts against gravity). The magnitude of the buoyant force is predicted from *Archimedes' principle (the buoyancy theorem)*: The buoyant force on a submerged object is equal to the weight of the displaced fluid.[21] An equivalent statement of Archimedes' principle is: A floating object displaces liquid equal in weight to its own weight.

[21] The volume term in Eq. 15.56 is the total volume of the object only in the case of complete submergence.

$$F_{\text{buoyant}} = \rho g V_{\text{displaced}} \quad \text{[SI]} \quad 15.56(a)$$

$$F_{\text{buoyant}} = \frac{\rho g V_{\text{displaced}}}{g_c} = \gamma V_{\text{displaced}} \quad \text{[U.S.]} \quad 15.56(b)$$

In the case of stationary (i.e., not moving vertically) floating or submerged objects, the buoyant force and object weight are in equilibrium. If the forces are not in equilibrium, the object will rise or fall until equilibrium is reached. That is, the object will sink until its remaining weight is supported by the bottom, or it will rise until the weight of displaced liquid is reduced by breaking the surface.[22]

The specific gravity (SG) of an object submerged in water can be determined from its dry and submerged weights. Neglecting the buoyancy of any surrounding gases,

$$\text{SG} = \frac{W_{\text{dry}}}{W_{\text{dry}} - W_{\text{submerged}}} \quad 15.57$$

Figure 15.21 illustrates an object floating partially exposed in a liquid. Neglecting the insignificant buoyant force from the displaced air (or other gas), the fractions of volume exposed and submerged are easily determined.

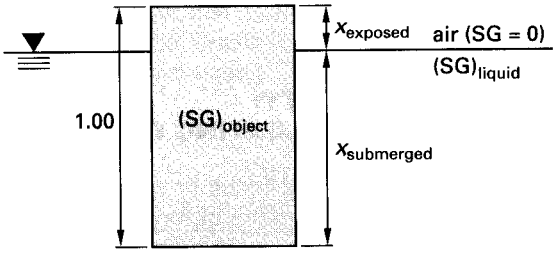

Figure 15.21 *Partially Submerged Object*

$$x_{\text{submerged}} = \frac{\rho_{\text{object}}}{\rho_{\text{liquid}}} = \frac{(\text{SG})_{\text{object}}}{(\text{SG})_{\text{liquid}}} \quad 15.58$$

$$x_{\text{exposed}} = 1 - x_{\text{submerged}} \quad 15.59$$

Figure 15.22 illustrates a somewhat more complicated situation—that of an object floating at the interface between two liquids of different densities. The fractions of immersion in each liquid are given by the following equations.

$$x_1 = \frac{(\text{SG})_2 - (\text{SG})_{\text{object}}}{(\text{SG})_2 - (\text{SG})_1} \quad 15.60$$

$$x_2 = 1 - x_1 = \frac{(\text{SG})_{\text{object}} - (\text{SG})_1}{(\text{SG})_2 - (\text{SG})_1} \quad 15.61$$

[22] An object can also stop rising or falling due to a change in the fluid's density. The buoyant force will increase with increasing depth in the ocean due to an increase in density at great depths. The buoyant force will decrease with increasing altitude in the atmosphere due to a decrease in density at great heights.

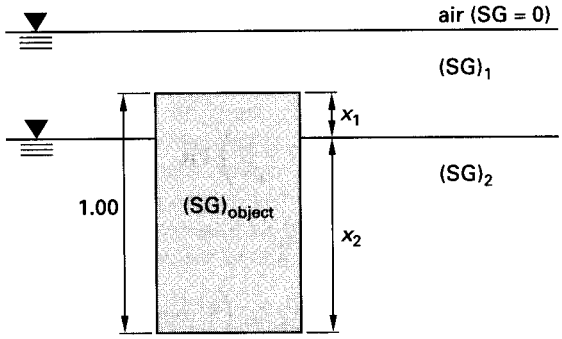

Figure 15.22 *Object Floating in Two Liquids*

A more general case of a floating object is shown in Fig. 15.23. Situations of this type are easily evaluated by equating the object's weight with the sum of the buoyant forces.

In the case of Fig. 15.23 (with two liquids), the following relationships apply.

$$(\text{SG})_{\text{object}} = x_1(\text{SG})_1 + x_2(\text{SG})_2 \quad 15.62$$

$$(\text{SG})_{\text{object}} = (1 - x_0 - x_2)(\text{SG})_1 + x_2(\text{SG})_2 \quad 15.63$$

$$(\text{SG})_{\text{object}} = x_1(\text{SG})_1 + (1 - x_0 - x_1)(\text{SG})_2 \quad 15.64$$

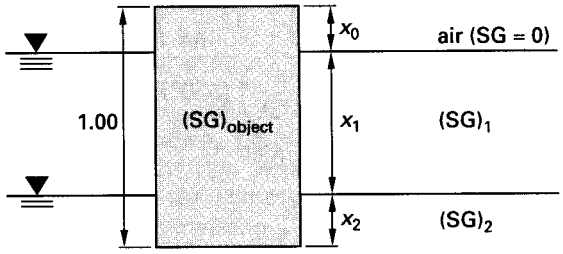

Figure 15.23 *General Two-Liquid Buoyancy Problem*

Example 15.8

An empty polyethylene telemetry balloon and payload have a mass of 500 lbm (225 kg). The balloon is filled with helium when the atmospheric conditions are 60°F (15.6°C) and 14.8 psia (102 kPa). The specific gas constant of helium is 2079 J/kg·K (386.3 ft-lbf/lbm-°R). What volume of helium is required for lift-off from a sea-level platform?

SI Solution

$$\rho_{\text{air}} = \frac{p}{RT} = \frac{1.02 \times 10^5 \text{ Pa}}{\left(286.7 \dfrac{\text{J}}{\text{kg·K}}\right)(15.6°\text{C} + 273)}$$

$$= 1.233 \text{ kg/m}^3$$

$$\rho_{\text{helium}} = \frac{1.02 \times 10^5 \text{ Pa}}{\left(2079 \frac{\text{J}}{\text{kg} \cdot \text{K}}\right)(288.6\text{K})} = 0.17 \text{ kg/m}^3$$

$$m = 225 \text{ kg} + \left(0.17 \frac{\text{kg}}{\text{m}^3}\right) V_{\text{He}}$$

$$m_b = \left(1.233 \frac{\text{kg}}{\text{m}^3}\right) V_{\text{He}}$$

$$225 \text{ kg} + \left(0.17 \frac{\text{kg}}{\text{m}^3}\right) V_{\text{He}} = \left(1.233 \frac{\text{kg}}{\text{m}^3}\right) V_{\text{He}}$$

$$V_{\text{He}} = 211.7 \text{ m}^3$$

Customary U.S. Solution

The gas densities are

$$\rho_{\text{air}} = \frac{p}{RT} = \frac{\left(14.8 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(53.3 \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(60°\text{F} + 460)}$$

$$= 0.07689 \text{ lbm/ft}^3$$

$$\gamma_{\text{air}} = \rho \times \frac{g}{g_c} = 0.07689 \text{ lbf/ft}^3$$

$$\rho_{\text{helium}} = \frac{\left(14.8 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(386.3 \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(520°\text{R})}$$

$$= 0.01061 \text{ lbm/ft}^3$$

$$\gamma_{\text{helium}} = 0.01061 \text{ lbf/ft}^3$$

The total weight of the balloon, payload, and helium is

$$W = 500 \text{ lbf} + \left(0.01061 \frac{\text{lbf}}{\text{ft}^3}\right) V_{\text{He}}$$

The buoyant force is the weight of the displaced air. Neglecting the payload volume, the displaced air volume is the same as the helium volume.

$$F_b = \left(0.07689 \frac{\text{lbf}}{\text{ft}^3}\right) V_{\text{He}}$$

At lift-off, the weight of the balloon is just equal to the buoyant force.

$$W = F_b$$

$$500 \text{ lbf} + \left(0.01061 \frac{\text{lbf}}{\text{ft}^3}\right) V_{\text{He}} = \left(0.07689 \frac{\text{lbf}}{\text{ft}^3}\right) V_{\text{He}}$$

$$V_{\text{He}} = 7544 \text{ ft}^3$$

19. BUOYANCY OF SUBMERGED PIPELINES

Whenever possible, submerged pipelines for river crossings should be completely buried at a level below river scour. This will reduce or eliminate loads and movement due to flutter, scour and fill, drag, collisions, and buoyancy. Submerged pipelines should cross at right angles to the river. For maximum flexibility, ductility, and weighting, pipelines should be made of thick-walled mild steel.

Submerged pipelines should be weighted to achieve a minimum of 20% negative buoyancy (i.e., an average density of 1.2 times the environment, approximately 72 lbm/ft^3 or 1200 kg/m^3). Metal or concrete clamps can be used for this purpose, as well as concrete coatings. Thick steel clamps have the advantage of a smaller lateral exposed area (resulting in less drag from river flow), while brittle concrete coatings are sensitive to pipeline flutter and temperature fluctuations.

Due to the critical nature of many pipelines and the difficulty in accessing submerged pipelines for repair, it is common to provide a parallel auxiliary line. The auxiliary and main lines are provided with crossover and mainline valves, respectively, on high ground at both sides of the river to permit either or both lines to be used.

20. INTACT STABILITY: STABILITY OF FLOATING OBJECTS

A stationary object is said to be in *static equilibrium*. However, an object in static equilibrium is not necessarily stable. For example, a coin balanced on edge is in static equilibrium, but it will not return to the balanced position if it is disturbed. An object is said to be *stable* (i.e., in *stable equilibrium*) if it tends to return to the equilibrium position when slightly displaced.

Stability of floating and submerged objects is known as *intact stability*.[23] There are two forces acting on a stationary floating object: the buoyant force and the object's weight. The buoyant force acts upward through the centroid of the displaced volume (not the object's volume). This centroid is known as the *center of buoyancy*. The gravitational force on the object (i.e., the object's weight) acts downward through the entire object's center of gravity.

For a totally submerged object (e.g., a balloon or submarine) to be stable, the center of buoyancy must be above the center of gravity. The object will be stable because a *righting moment* will be created if the object tips over, since the center of buoyancy will move outward from the center of gravity.

[23]The subject of intact stability, being a part of naval architecture curriculum, is not covered extensively in most fluids books. However, it is covered extensively in basic ship design and naval architecture books.

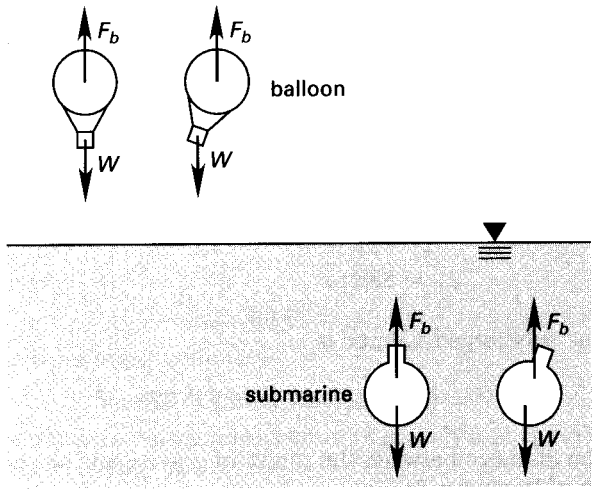

Figure 15.24 *Stability of a Submerged Object*

The stability criterion is different for partially submerged objects (e.g., surface ships). For partially submerged objects to be stable, the *metacenter* must be above the center of gravity. If the vessel shown in Fig. 15.25 heels (i.e., lists or rolls), the location of the center of gravity of the object does not change.[24] However, the center of buoyancy shifts to the centroid of the new submerged section 123. The centers of buoyancy and gravity are no longer in line. The righting couple resists further overturning.

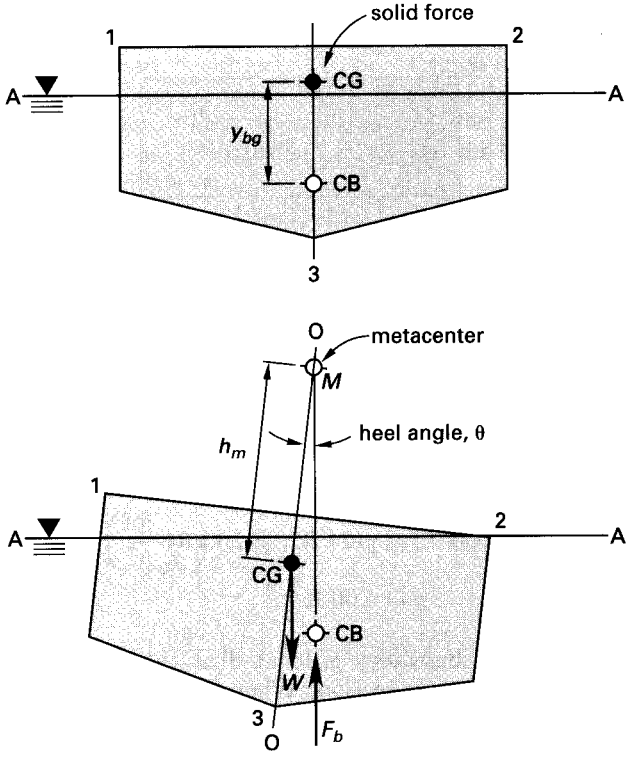

Figure 15.25 *Stability of a Partially Submerged Floating Object*

[24]The verbs *roll, list* and *heel* are synonymous.

This righting couple exists when the extension of the buoyant force, F_b, intersects line O-O above the center of gravity at M, the *metacenter*. If M lies below the center of gravity, an overturning couple will exist. The distance between the center of gravity and the metacenter is called the *metacentric height*, and it is reasonably constant for heel angles less than 10°. Also, for angles less than 10°, the center of buoyancy follows a locus for which the metacenter is the instantaneous center.

The metacentric height is one of the most important and basic parameters in ship design. It determines the ship's ability to remain upright as well as the ship's roll and pitch characteristics.

"Acceptable" minimum values of the metacentric height have been established from experience, and these depend on the ship type and class. For example, many submarines are required to have a metacentric height of 1 ft (0.3 m) when surfaced. This will increase to approximately 3.5 ft (1.2 m) for some of the largest surface ships. If an acceptable metacentric height is not achieved initially, the center of gravity must be lowered or the keel depth increased. The beam width can also be increased slightly to increase the waterplane moment of inertia.

For a surface vessel rolling through an angle less than approximately 10°, the distance between the vertical center of gravity and the metacenter can be found from Eq. 15.65. Variable I is the centroidal area moment of inertia of the original waterline (free surface) cross section about a longitudinal (fore and aft) waterline axis; V is the displaced volume.

If the distance, y_{bg}, separating the centers of buoyancy and gravity is known, Eq. 15.65 can be solved for the metacentric height. y_{bg} is positive when the center of gravity is above the center of buoyancy. This is the normal case. Otherwise, y_{bg} is negative.

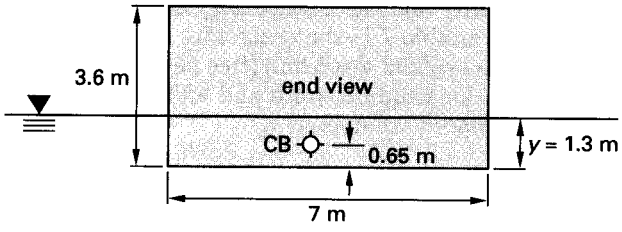
$$y_{bg} + h_m = \frac{I}{V} \qquad 15.65$$

The righting moment (also known as the *restoring moment*) is the stabilizing moment exerted when the ship rolls. Values of the righting moment are typically specified with units of foot-tons (MN·m).

$$M_{\text{righting}} = h_m \gamma_w V_{\text{displaced}} \sin\theta \qquad 15.66$$

The transverse (roll) and longitudinal (pitch) *periods* also depend on the metacentric height. The roll characteristics are found from the differential equation formed by equating the righting moment to the product of the ship's transverse mass moment of inertia and the angular acceleration. Larger metacentric heights result in lower roll periods. If k is the radius of gyration about the roll axis, the roll period is

$$T_{\text{roll}} = \frac{2\pi k}{\sqrt{g h_m}} \qquad 15.67$$



The roll and pitch periods must be adjusted for the appropriate level of crew and passenger comfort. A "beamy" ice-breaking ship will have a metacentric height much larger than normally required for intact stability, resulting in a low, nauseating, roll period. The designer of a passenger ship, however, would have to decrease the intact stability (i.e., decrease the metacentric height) in order to achieve an acceptable ride characteristic. This requires a metacentric height that is less than approximately 6% of the beam length.

Example 15.9

A 600,000 lbm (280 000 kg) rectangular barge has external dimensions of 24 ft width, 98 ft length, and 12 ft height (7 m × 30 m × 3.6 m). It floats in seawater ($\gamma_w = 64.0$ lbf/ft^3; $\rho_w = 1024$ kg/m^3). The center of gravity is 7.8 ft (2.4 m) from the top of the barge as loaded. Find (a) the location of the center of buoyancy when the barge is floating on an even keel, and (b) the approximate location of the metacenter when the barge experiences a 5° heel.

SI Solution

(a) Refer to the following diagram. Let dimension y represent the depth of the submerged barge.

From Archimedes' principle, the buoyant force equals the weight of the barge. This, in turn, equals the weight of the displaced seawater.

$$F_b = W = V\gamma_w = V\rho_w g$$

$$(280\,000 \text{ kg})\left(9.81 \frac{\text{m}}{\text{s}^2}\right) = y(7 \text{ m})(30 \text{ m})\left(1024 \frac{\text{kg}}{\text{m}^3}\right) \times \left(9.81 \frac{\text{m}}{\text{s}^2}\right)$$

$$y = 1.30 \text{ m}$$

The center of buoyancy is located at the centroid of the submerged cross section. When floating on an even keel, the submerged cross section is rectangular with a height of 1.30 m. The height of the center of buoyancy above the keel is

$$\frac{1.30 \text{ m}}{2} = 0.65 \text{ m}$$

(b) While the location of the new center of buoyancy can be determined, the location of the metacenter does not change significantly for small angles of heel. Therefore, for approximate calculations, the angle of heel is not significant.

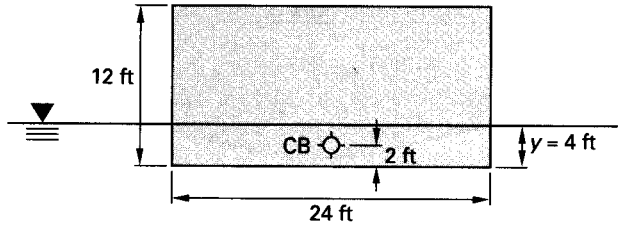
The area moment of inertia of the longitudinal waterline cross section is

$$I = \frac{Lw^3}{12} = \frac{(30 \text{ m})(7 \text{ m})^3}{12} = 858 \text{ m}^4$$

The submerged volume is

$$V = (1.3 \text{ m})(7 \text{ m})(30 \text{ m}) = 273 \text{ m}^3$$

The distance between the center of gravity and the center of buoyancy is



$$y_{bg} = 3.6 \text{ m} - 2.4 \text{ m} - 0.65 \text{ m} = 0.55 \text{ m}$$

The metacentric height measured above the center of gravity is

$$h_m = \frac{I}{V} - y_{bg} = \frac{858 \text{ m}^4}{273 \text{ m}^3} - 0.55 \text{ m} = 2.6 \text{ m}$$

Customary U.S. Solution

(a) Refer to the following diagram. Let dimension y represent the depth of the submerged barge.

From Archimedes' principle, the buoyant force equals the weight of the barge. This, in turn, equals the weight of the displaced seawater.

$$F_b = W = V\gamma_w$$

$$600{,}000 \text{ lbf} = y(24 \text{ ft})(98 \text{ ft})\left(64 \frac{\text{lbf}}{\text{ft}^3}\right)$$

$$y = 4.00 \text{ ft}$$

The center of buoyancy is located at the centroid of the submerged cross section. When floating on an even keel, the submerged cross section is rectangular with a height of 4.00 ft. The height of the center of buoyancy above the keel is

$$\frac{4.00 \text{ ft}}{2} = 2.00 \text{ ft}$$

(b) While the location of the new center of buoyancy can be determined, the location of the metacenter does not change significantly for small angles of heel. Therefore, for approximate calculations, the angle of heel is not significant.

The area moment of inertia of the longitudinal waterline cross section is

$$I = \frac{Lw^3}{12} = \frac{(98\text{ ft})(24\text{ ft})^3}{12}$$
$$= 112{,}900\text{ ft}^4$$

The submerged volume is

$$V = (4\text{ ft})(24\text{ ft})(98\text{ ft}) = 9408\text{ ft}^3$$

The distance between the center of gravity and the center of buoyancy is

$$y_{bg} = 12\text{ ft} - 7.8\text{ ft} - 2.0\text{ ft} = 2.2\text{ ft}$$

The metacentric height measured above the center of gravity is

$$h_m = \frac{I}{V} - y_{bg}$$
$$= \frac{112{,}900\text{ ft}^4}{9408\text{ ft}^3} - 2.2\text{ ft}$$
$$= 9.8\text{ ft}$$

21. FLUID MASSES UNDER EXTERNAL ACCELERATION

Up to this point, fluid masses have been stationary, and gravity has been the only force acting on them. If a fluid mass is subjected to an external acceleration (moved sideways, rotated, etc.), an additional force will be introduced. This force will change the equilibrium position of the fluid surface as well as the hydrostatic pressure distribution.

Figure 26 illustrates a liquid mass subjected to constant accelerations in the vertical and/or horizontal directions. (a_y is negative if the acceleration is downward.) The surface is inclined at the angle predicted by Eq. 15.68. The planes of equal hydrostatic pressure beneath the surface are also inclined at the same angle.[25]

$$\theta = \arctan\left(\frac{a_x}{a_y + g}\right) \qquad 15.68$$

$$p = \rho g h\left(1 + \frac{a_y}{g}\right) \qquad \text{[SI]} \quad 15.69(a)$$

$$p = \left(\frac{\rho g h}{g_c}\right)\left(1 + \frac{a_y}{g}\right) = \gamma h\left(1 + \frac{a_y}{g}\right) \qquad \text{[U.S.]} \quad 15.69(b)$$

[25]Once the orientation of the surface is known, the pressure distribution can be determined without considering the acceleration. The hydrostatic pressure at a point depends only on the height of the liquid above that point. The acceleration affects that height but does not change the $p = \rho g h$ relationship.

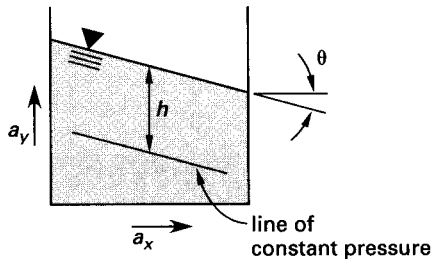


Figure 15.26 *Fluid Mass Under Constant Linear Acceleration*

Figure 15.27 illustrates a fluid mass rotating at constant angular velocity, ω in rad/sec.[26] The resulting surface is parabolic in shape. The elevation of the fluid surface at point A at distance r from the axis of rotation is given by Eq. 15.71. The distance h in Fig. 15.27 is measured from the lowest fluid elevation during rotation. h is not measured from the original elevation of the stationary fluid.

$$\theta = \arctan\left(\frac{\omega^2 r}{g}\right) \qquad 15.70$$

$$h = \frac{(\omega r)^2}{2g} = \frac{v^2}{2g} \qquad 15.71$$

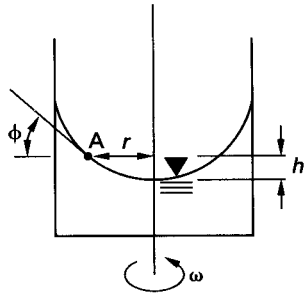

Figure 15.27 *Rotating Fluid Mass*

PRACTICE PROBLEMS

(Use $g = 32.2\text{ ft/sec}^2$ or 9.81 m/s^2 unless told to do otherwise in the problem.)

Buoyancy

1. A blimp contains 10,000 lbm (4500 kg) of hydrogen (specific gas constant = 766.5 ft-lbf/lbm-°R (4124 J/kg·K)) at 56°F (13°C) and 30.2 in Hg (770 mm Hg).

[26]Even though the rotational speed is not increasing, the fluid mass experiences a constant *centripetal acceleration* radially outward from the axis of rotation.

What is its lift if the hydrogen and air are in thermal and pressure equilibrium?

(A) 7.6×10^3 lbf (3.4×10^4 N)
(B) 1.2×10^4 lbf (5.3×10^4 N)
(C) 1.3×10^5 lbf (5.9×10^5 N)
(D) 1.7×10^5 lbf (7.7×10^5 N)

The answer is (C).

2. A hollow 6 ft (1.8 m) diameter sphere floats half-submerged in seawater. What mass of concrete is required as an external anchor to just submerge the sphere completely?

(A) 2700 lbm (1200 kg)
(B) 4200 lbm (1900 kg)
(C) 5500 lbm (2500 kg)
(D) 6300 lbm (2700 kg)

The answer is (D).

1. INTRODUCTION TO FLUID ENERGY UNITS

Several important fluids and thermodynamics equations, such as Bernoulli's equation and the steady-flow energy equation, are special applications of the *conservation of energy* concept. However, it is not always obvious how some formulations of these equations can be termed "energy." For example, elevation (z), with units of feet, is often called *gravitational energy.*[1]

Since every fluids problem is different, energy must be expressed per unit mass (i.e., *specific energy*). With SI formulations, the choice of units is unambiguous: J/kg is the only choice.

$$\frac{\text{J}}{\text{kg}} = \frac{\text{N·m}}{\text{kg}} = \frac{\text{m}^2}{\text{s}^2} \qquad 16.1$$

With problems formulated in English units, specific energy units will be ft-lbf/lbm.[2] (If the consistent set of units ft-lbf/slug is chosen, the same equations can be used with SI and consistent English units, since the primary dimensions are the same, that is, L^2/θ^2.)

$$\frac{\text{ft-lbf}}{\text{slug}} = \frac{\text{ft}^2}{\text{sec}^2} \qquad 16.2$$

The gravitational conversion constant, g_c, must be used if the units ft-lbf/lbm are used for specific fluid energy.

In many cases, the ratio g/g_c appears in equations. Since g and g_c have the same numerical value in most

[1] Foot and ft-lbf/lbm may be thought of as one and the same. Certainly, the set of units ft-lbf/lbm represents energy per unit mass. Unfortunately, lbf and lbm do not really cancel out to yield ft.

[2] Btu could be used for energy, as is common in thermodynamics problems, instead of ft-lbf. However, this is almost never done in fluids problems.

instances, this ratio affects the units without affecting the calculation. Because of this, some engineers omit the term g/g_c entirely. While it is easy to justify such a practice, the resulting equations are not dimensionally consistent.[3]

2. KINETIC ENERGY

Energy is required to accelerate a stationary body. Thus, a moving mass of fluid possesses more energy than an identical, stationary mass. The energy difference is the *kinetic energy* of the fluid.[4] If the kinetic energy is evaluated per unit mass, the term *specific kinetic energy* is used. Equation 16.3 gives the specific kinetic energy corresponding to a velocity, v.

$$E_{\mathrm{v}} = \frac{\mathrm{v}^2}{2} \qquad \text{[SI]} \qquad \textit{16.3(a)}$$

$$E_{\mathrm{v}} = \frac{\mathrm{v}^2}{2g_c} \qquad \text{[U.S.]} \qquad \textit{16.3(b)}$$

The units of specific kinetic energy in consistent units are clearly $\mathrm{m}^2/\mathrm{s}^2$ or $\mathrm{ft}^2/\mathrm{sec}^2$, which coincide with Eqs. 16.1 and 16.2 as representing energy per consistent mass unit. The units in traditional English units are

$$\frac{\left(\frac{\mathrm{ft}}{\mathrm{sec}}\right)^2}{\frac{\text{lbm-ft}}{\text{lbf-sec}^2}} = \frac{\text{ft-lbf}}{\text{lbm}} \qquad \textit{16.4}$$

3. POTENTIAL ENERGY

Work is performed in elevating a body. Thus, a mass of fluid at a high elevation will have more energy than an identical mass of fluid at a lower elevation. The energy difference is the *potential energy* of the fluid.[5] Like kinetic energy, potential energy is usually expressed per unit mass. Equation 16.5 gives the potential energy of fluid at an elevation z.

$$E_z = zg \qquad \text{[SI]} \qquad \textit{16.5(a)}$$

$$E_z = \frac{zg}{g_c} \qquad \text{[U.S.]}[6] \qquad \textit{16.5(b)}$$

The units of potential energy in a consistent system are again $\mathrm{m}^2/\mathrm{s}^2$ or $\mathrm{ft}^2/\mathrm{sec}^2$. The units in a traditional English system are ft-lbf/lbm.

[3]More than being dimensionally inconsistent, the resulting equations will be numerically incorrect in any nonstandard (other than one gravity) gravitational field.

[4]The terms *velocity energy* and *dynamic energy* are used less often.

[5]The term *gravitational energy* is also used.

[6]Since $g = g_c$ (numerically), it is tempting to write $E_z = z$. In fact, many engineers in the United States do just that.

z is the elevation of the fluid. The reference point (i.e., zero elevation point) is entirely arbitrary and can be chosen for convenience. This is because potential energy always appears in a difference equation (i.e., ΔE_z), and the reference point cancels out.

4. PRESSURE ENERGY

Work is performed and energy is expended when a substance is compressed. Thus, a mass of fluid at a high pressure will have more energy than an identical mass of fluid at a lower pressure. The energy difference is the *pressure energy* of the fluid.[7] Pressure energy is usually found in equations along with kinetic and potential energies, and is expressed as energy per unit mass. Equation 16.6 gives the pressure energy of fluid at pressure p.

$$E_p = \frac{p}{\rho} \qquad \textit{16.6}$$

The consistent SI units of pressure energy are

$$\frac{\mathrm{Pa \cdot m}^3}{\mathrm{kg}} = \frac{\mathrm{N \cdot m}}{\mathrm{kg}} = \frac{\mathrm{J}}{\mathrm{kg}} \qquad \textit{16.7}$$

The units of pressure energy in the consistent English system are

$$\frac{\text{lbf-ft}^3}{\text{ft}^2\text{-slug}} = \frac{\text{ft-lbf}}{\text{slug}} \qquad \textit{16.8}$$

The units of pressure energy in the traditional English system are

$$\frac{\text{lbf-ft}^3}{\text{ft}^2\text{-lbm}} = \frac{\text{ft-lbf}}{\text{lbm}} \qquad \textit{16.9}$$

5. BERNOULLI EQUATION

The *Bernoulli equation* is an energy conservation equation based on several reasonable assumptions. The equation assumes the following.

- The fluid is incompressible.
- There is no fluid friction.
- Changes in thermal energy are negligible.[8]

The Bernoulli equation states that the *total energy* of a fluid flowing without friction losses in a pipe is constant.[9] The total energy possessed by the fluid is the

[7]The terms *static energy* and *flow energy* are also used. The name *flow energy* results from the need to push (pressurize) a fluid to get it to flow through a pipe. However, flow energy and kinetic energy are not the same.

[8]In thermodynamics, the fluid flow is said to be *adiabatic*.

[9]Strictly speaking, this is the *total specific energy*, since the energy is per unit mass. However, the word "specific," being understood, is seldom used. Of course, "the total energy of the system" means something else and requires knowing the fluid mass in the system.

sum of its pressure, kinetic, and potential energies. Drawing on Eqs. 16.3, 16.5, and 16.6, the Bernoulli equation is written as

$$E_t = E_p + E_v + E_z \qquad 16.10$$

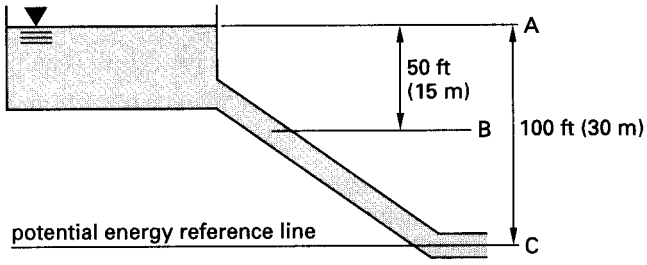
$$E_t = \frac{p}{\rho} + \frac{v^2}{2} + zg \quad \text{[SI]} \qquad 16.11(a)$$

$$E_t = \frac{p}{\rho} + \frac{v^2}{2g_c} + \frac{zg}{g_c} \quad \text{[U.S.]} \qquad 16.11(b)$$

Equation 16.11 is valid for both laminar and turbulent flows. It can also be used for gases and vapors if the incompressibility assumption is valid.[10]

The quantities known as *total head*, h_t, and *total pressure*, p_t, can be calculated from total energy.

$$h_t = \frac{E_t}{g} \quad \text{[SI]} \qquad 16.12(a)$$



$$h_t = E_t \times \frac{g_c}{g} \quad \text{[U.S.]} \qquad 16.12(b)$$

$$p_t = \rho g h_t \quad \text{[SI]} \qquad 16.13(a)$$

$$p_t = \rho h_t \times \frac{g}{g_c} \quad \text{[U.S.]} \qquad 16.13(b)$$

Example 16.1

A pipe draws water from the bottom of a reservoir and discharges it freely at point C, 100 ft (30 m) below the surface. The flow is frictionless. (a) What is the total specific energy at an elevation 50 ft (15 m) below the water surface (i.e., point B)? (b) What is the velocity at point C?

SI Solution

(a) At point A, the velocity and gage pressure are both zero. Therefore, the total energy consists only of potential energy. Point C is chosen as the reference ($z = 0$) elevation.

$$E_A = z_A g = (30 \text{ m})\left(9.81 \frac{\text{m}}{\text{s}^2}\right)$$
$$= 294.3 \text{ m}^2/\text{s}^2 \text{ (J/kg)}$$

[10] A gas or vapor can be considered to be incompressible as long as its pressure does not change by more than 10% between the entrance and exit, and its velocity is less than Mach 0.3 everywhere.

At point B, the fluid is moving and possesses kinetic energy. The fluid is also under hydrostatic pressure and possesses pressure energy. These energy forms have come at the expense of potential energy. (This is a direct result of the Bernoulli equation.) Also, the flow is frictionless. Thus, there is no net change in the total energy between points A and B.

$$E_B = E_A = 294.3 \text{ m}^2/\text{s}^2 \text{ (J/kg)}$$

(b) At point C, the gage pressure and pressure energy are again zero, since the discharge is at atmospheric pressure. The potential energy is zero, since $z = 0$. The total energy of the system has been converted to kinetic energy. From Eq. 16.11,

$$E_t = 294.3 \frac{\text{m}^2}{\text{s}^2} = 0 + \frac{v^2}{2} + 0$$
$$v = 24.3 \text{ m/s}$$

Customary U.S. Solution

(a)
$$E_A = \frac{z_A g}{g_c} = \frac{(100 \text{ ft})\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}$$
$$= 100 \text{ ft-lbf/lbm}$$
$$E_B = E_A = 100 \text{ ft-lbf/lbm}$$

(b)
$$E_t = 100 \frac{\text{ft-lbf}}{\text{lbm}} = 0 + \frac{v^2}{2g_c} + 0$$
$$v^2 = (2)\left(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)\left(100 \frac{\text{ft-lbf}}{\text{lbm}}\right)$$
$$= 6440 \text{ ft}^2/\text{sec}^2$$
$$v = 80.2 \text{ ft/sec}$$

Example 16.2

Water (62.4 lbm/ft^3; 1000 kg/m^3) is pumped up a hillside into a reservoir. The pump discharges water at the rate of 6 ft/sec (2 m/s) and pressure of 150 psig (1000 kPa). Disregarding friction, what is the maximum elevation (above the centerline of the pump's discharge) of the reservoir's water surface?

SI Solution

At the centerline of the pump's discharge, the potential energy is zero. The pressure and velocity energies are

$$E_p = \frac{p}{\rho} = \frac{(1000 \text{ kPa})\left(1000 \frac{\text{Pa}}{\text{kPa}}\right)}{1000 \frac{\text{kg}}{\text{m}^3}} = 1000 \text{ J/kg}$$

$$E_v = \frac{v^2}{2} = \frac{\left(2 \frac{\text{m}}{\text{s}}\right)^2}{2} = 2 \text{ J/kg}$$

The total energy at the pump's discharge is

$$E_{t,1} = E_p + E_v$$
$$= 1000\ \frac{\text{J}}{\text{kg}} + 2\ \frac{\text{J}}{\text{kg}} = 1002\ \text{J/kg}$$

Since the flow is frictionless, the same energy is possessed by the water at the reservoir's surface. Since the velocity and gage pressure at the surface are zero, all of the available energy has been converted to potential energy.

$$E_{t,2} = E_{t,1}$$
$$z_2 g = 1002\ \text{J/kg}$$
$$z_2 = \frac{E_{t,2}}{g} = \frac{1002\ \frac{\text{J}}{\text{kg}}}{9.81\ \frac{\text{m}}{\text{s}^2}} = 102.1\ \text{m}$$

Notice that the volumetric flow rate of the water is not relevant since the water velocity was known. Similarly, the pipe size is not needed.

Customary U.S. Solution

$$E_p = \frac{p}{\rho} = \frac{\left(150\ \frac{\text{lbf}}{\text{in}^2}\right)\left(144\ \frac{\text{in}^2}{\text{ft}^2}\right)}{62.4\ \frac{\text{lbm}}{\text{ft}^3}}$$
$$= 346.15\ \text{ft-lbf/lbm}$$

$$E_v = \frac{v^2}{2g_c} = \frac{\left(6\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)}$$
$$= 0.56\ \text{ft-lbf/lbm}$$

$$E_{t,1} = E_p + E_v$$
$$= 346.15\ \frac{\text{ft-lbf}}{\text{lbm}} + 0.56\ \frac{\text{ft-lbf}}{\text{lbm}} = 346.71\ \text{ft-lbf/lbm}$$

$$E_{t,2} = E_{t,1}$$
$$\frac{z_2 g}{g_c} = 346.71\ \text{ft-lbf/lbm}$$
$$z_2 = \frac{E_{t,2} g_c}{g} = \frac{\left(346.71\ \frac{\text{ft-lbf}}{\text{lbm}}\right)\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)}{32.2\ \frac{\text{ft}}{\text{sec}^2}}$$
$$= 346.71\ \text{ft}$$

6. PITOT TUBE

A *pitot tube* (also known as an *impact tube* or *stagnation tube*) is simply a hollow tube that is placed longitudinally in the direction of fluid flow, allowing the flow to enter one end at the fluid's *velocity of approach*. It is used to measure velocity of flow and finds uses in both subsonic and supersonic applications.

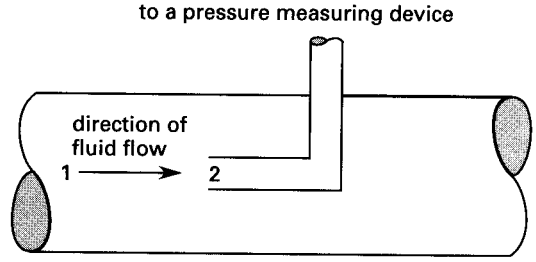


Figure 16.1 *Pitot Tube*

When the fluid enters the pitot tube, it is forced to come to a stop (at the *stagnation point*), and the velocity energy is transformed into pressure energy. If the fluid is a low-velocity gas, the stagnation is assumed to occur without compression heating of the gas. If there is no friction (the common assumption), the process is said to be adiabatic.

Bernoulli's equation can be used to predict the static pressure at the stagnation point. Since the velocity of the fluid within the pitot tube is zero, the upstream velocity can be calculated if the static and stagnation pressures are known.

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} = \frac{p_2}{\rho} \qquad 16.14$$

$$v_1 = \sqrt{\frac{2(p_2 - p_1)}{\rho}} \qquad \text{[SI]} \quad 16.15(a)$$

$$v_1 = \sqrt{\frac{2g_c(p_2 - p_1)}{\rho}} \qquad \text{[U.S.]} \quad 16.15(b)$$

In reality, both friction and heating occur, and the fluid may be compressible. These errors are taken care of by a correction factor known as the *impact factor*, C_i, which is applied to the derived velocity. C_i is usually very close to 1.00 (e.g., 0.99 or 0.995).

$$v_{\text{actual}} = C_i\ v_{\text{indicated}}$$

Since accurate measurements of fluid velocity are dependent on one-dimensional fluid flow, it is essential that any obstructions or pipe bends be more than ten pipe diameters upstream from the pitot tube.

7. IMPACT ENERGY

Impact energy, E_i (also known as *stagnation energy* and *total energy*), is the sum of the kinetic and pressure energy terms.[11] Equation 16.17 is applicable to fluids

[11] It is confusing to label Eq. 16.16 *total* when the gravitational energy term has been omitted. However, the reference point for gravitational energy is arbitrary, and in this application the reference coincides with the centerline of the fluid flow. In truth, the effective pressure developed in a fluid which has been brought to rest adiabatically does not depend on the elevation or altitude of the fluid. This situation is seldom ambiguous. The application will determine which definition of total head or total energy is intended.

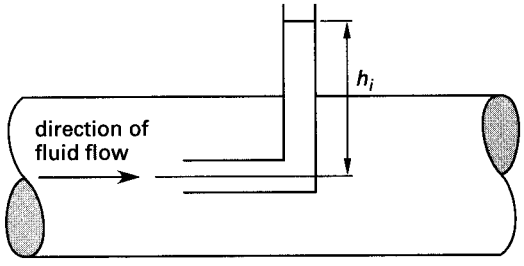
and gases flowing with velocities less than approximately Mach 0.3.

$$E_i = E_p + E_v \qquad 16.16$$

$$E_i = \frac{p}{\rho} + \frac{v^2}{2} \qquad \text{[SI]} \qquad 16.17(a)$$

$$E_i = \frac{p}{\rho} + \frac{v^2}{2g_c} \qquad \text{[U.S.]} \qquad 16.17(b)$$

Impact head, h_i, is calculated from the impact energy in a manner analogous to Eq. 16.12. Impact head represents the height the liquid will rise in a piezometer-pitot tube when the fluid has been brought to rest (i.e., stagnated) in an adiabatic manner. Such a case is illustrated in Fig. 16.2. If a gas or high-velocity, high-pressure fluid is flowing, it will be necessary to use a mercury manometer or pressure gauge to measure stagnation head.



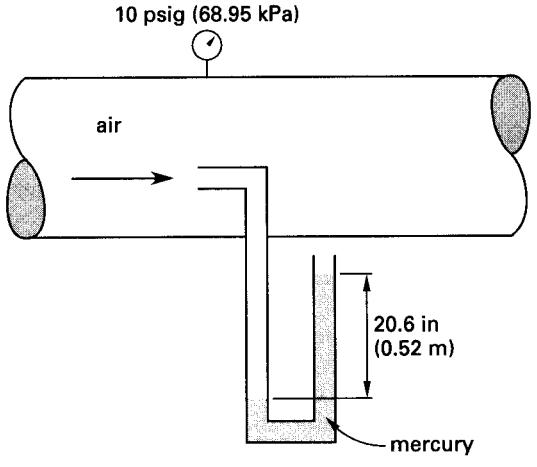


Figure 16.2 *Pitot Tube-Piezometer Apparatus*

Example 16.3

The static pressure of air (0.075 lbm/ft^3; 1.2 kg/m^3) flowing in a pipe is measured by a precision gauge to be 10.00 psig (68.95 kPa). A pitot tube-manometer indicates 20.6 in (0.52 m) of mercury. Losses are insignificant. What is the velocity of the air in the pipe?

SI Solution

From Table 14.2, the density of mercury is 13 600 kg/m^3. The impact pressure is

$$\begin{aligned} p_i &= \rho g h \\ &= \left(13\,600\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)\left(\frac{0.52\ \text{m}}{1000\ \frac{\text{Pa}}{\text{kPa}}}\right) \\ &= 69.38\ \text{kPa} \end{aligned}$$

From Eq. 16.15, the velocity is

$$\begin{aligned} v &= \sqrt{\frac{2(p_i - p_s)}{\rho}} \\ &= \sqrt{\frac{(2)(69.38\ \text{kPa} - 68.95\ \text{kPa})\left(1000\ \frac{\text{Pa}}{\text{kPa}}\right)}{1.2\ \frac{\text{kg}}{\text{m}^3}}} \\ &= 26.8\ \text{m/s} \end{aligned}$$

Customary U.S. Solution

The pitot tube measures impact (stagnation) pressure. From Table 15.2, the fluid height equivalent (specific weight) of mercury is 0.491 psi/in. Therefore, the impact pressure is

$$p_i = (20.6\ \text{in})\left(0.491\ \frac{\text{psi}}{\text{in}}\right) = 10.11\ \text{psig}$$

Since impact pressure is the sum of the static and kinetic (velocity) pressures, the kinetic pressure is

$$\begin{aligned} p_v &= p_i - p_s \\ &= 10.11\ \text{psig} - 10.00\ \text{psig} = 0.11\ \text{psi} \end{aligned}$$

The velocity is calculated from Eq. 16.15.

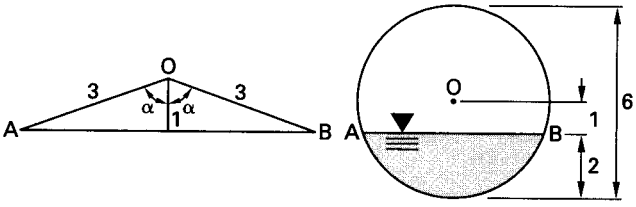
$$\begin{aligned} v &= \sqrt{\frac{2g_c(p_i - p_s)}{\rho}} \\ &= \sqrt{\frac{(2)\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)\left(0.11\ \frac{\text{lbf}}{\text{in}^2}\right)\left(144\ \frac{\text{in}^2}{\text{ft}^2}\right)}{0.075\ \frac{\text{lbm}}{\text{ft}^3}}} \\ &= 117\ \text{ft/sec} \end{aligned}$$

8. HYDRAULIC RADIUS

The *hydraulic radius* is defined as the area in flow divided by the *wetted perimeter*.[12] (The hydraulic radius is not the same as the radius of a pipe.) The area in flow is the cross-sectional area of the fluid flowing. When a fluid is flowing under pressure in a pipe (i.e., *pressure flow*), the area in flow will be the internal area of the pipe. However, the fluid may not completely fill the pipe and may flow simply because of a sloped surface (i.e., *gravity flow* or *open channel flow*).

The wetted perimeter is the length of the line representing the interface between the fluid and the pipe or channel. It does not include the *free surface* length (i.e., the interface between fluid and atmosphere).

$$r_h = \frac{\text{area in flow}}{\text{wetted perimeter}} = \frac{A}{s} \qquad 16.18$$



Consider a circular pipe flowing completely full. The area in flow is πr^2. The wetted perimeter is the entire circumference, $2\pi r$. The hydraulic radius is

$$r_{h,\text{pipe}} = \frac{\pi r^2}{2\pi r} = \frac{r}{2} \qquad 16.19$$

The hydraulic radius of a pipe flowing half full is also $r/2$, since the flow area and wetted perimeter are both halved. However, it is time-consuming to calculate the hydraulic radius for pipe flow at any intermediate depth, due to the difficulty in evaluating the flow area and wetted perimeter. Appendix 16.A greatly simplifies such calculations.

Example 16.4

A pipe (internal diameter = 6 units) carries water with a depth of 2 units flowing under the influence of gravity. (a) Calculate the hydraulic radius analytically. (b) Verify the result by using App. 16.A.

Solution

(a) The equations for a circular segment must be used. The radius is $6/2 = 3$.

Points A, O, and B are used to find the central angle of the circular segment.

$$\begin{aligned}\phi = 2\alpha &= 2\left(\arccos\left(\tfrac{1}{3}\right)\right) \\ &= (2)(70.53^\circ) = 141.06^\circ\end{aligned}$$

ϕ must be expressed in radians.

$$\phi = 2\pi\left(\frac{141.06^\circ}{360^\circ}\right) = 2.46 \text{ rad}$$

The area of the circular segment (i.e., the area in flow) is

$$\begin{aligned}A &= \tfrac{1}{2}r^2(\phi - \sin\phi) \quad [\phi \text{ in radians}] \\ &= (0.5)(3)^2(2.46 \text{ rad} - \sin(2.46 \text{ rad})) \\ &= 8.235 \text{ units}^2\end{aligned}$$

The arc length (i.e., the wetted perimeter) is

$$s = r\phi = (3)(2.46 \text{ rad}) = 7.38 \text{ units}$$

The hydraulic radius is

$$r_h = \frac{A}{s} = \frac{8.235 \text{ units}^2}{7.38 \text{ units}} = 1.12 \text{ units}$$

(b) The ratio d/D is needed to use App. 16.A.

$$\frac{d}{D} = \frac{2 \text{ units}}{6 \text{ units}} = 0.333$$

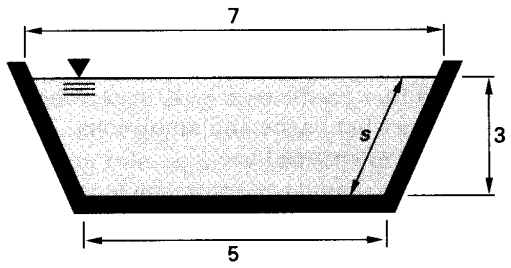
From App. 16.A,

$$\begin{aligned}\frac{r_h}{D} &\approx 0.186 \\ r_h &= (0.186)(6 \text{ units}) = 1.12 \text{ units}\end{aligned}$$

9. EQUIVALENT DIAMETER

Many fluid, thermodynamic, and heat transfer processes are dependent on the physical length of an object. The general name for this controlling variable is *characteristic dimension*. The characteristic dimension in evaluating fluid flow is the *equivalent diameter* (also known as the *hydraulic diameter*). The equivalent diameter for a full-flowing pipe is simply its inside diameter. The equivalent diameters of other cross sections in flow are given in Table 16.1. If the hydraulic radius is known, it can be used to calculate the equivalent diameter.

$$D_e = 4r_h \qquad 16.20$$



[12]The hydraulic radius can also be calculated as one-fourth of the equivalent diameter of the pipe or channel, as will be subsequently shown. That is, $r_h = \frac{1}{4}D_e$.

Table 16.1 *Equivalent Diameters for Common Conduit Shapes*

conduit cross section	D_e
flowing full	
annulus (outer diameter D_o, inner diameter D_i)	$D_o - D_i$
square (side L)	L
rectangle (sides L_1 and L_2)	$\frac{2L_1L_2}{L_1+L_2}$
flowing partially full	
half-filled circle (diameter D)	D
rectangle (h deep, L wide)	$\frac{4hL}{L+2h}$
wide, shallow stream (h deep)	$4h$
triangle (h deep, L broad, s side)	$\frac{hL}{s}$
trapezoid (h deep, a wide at top, b wide at bottom, s side)	$\frac{2h(a+b)}{b+2s}$

Example 16.5

Determine the equivalent diameter and hydraulic radius for the open trapezoidal channel shown.

Solution

$$s = \sqrt{(3)^2 + (1)^2} = 3.16$$

Using Table 16.1,

$$D_e = \frac{2h(a+b)}{b+2s} = \frac{(2)(3)(7+5)}{5+(2)(3.16)} = 6.36$$

From Eq. 16.20,

$$r_h = \frac{D_e}{4} = \frac{6.36}{4} = 1.59$$

10. REYNOLDS NUMBER

The *Reynolds number*, Re, is a dimensionless number interpreted as the ratio of inertial forces to viscous forces in the fluid.[13]

$$\mathrm{Re} = \frac{\text{inertial forces}}{\text{viscous forces}} \qquad 16.21$$

The inertial forces are proportional to the flow diameter, velocity, and fluid density. (Increasing these variables will increase the momentum of the fluid in flow.) The viscous force is represented by the fluid's absolute viscosity, μ. Thus, the Reynolds number is calculated as

$$\mathrm{Re} = \frac{D_e \mathrm{v} \rho}{\mu} \quad \text{[SI]} \qquad 16.22(a)$$

$$\mathrm{Re} = \frac{D_e \mathrm{v} \rho}{g_c \mu} \quad \text{[U.S.]} \qquad 16.22(b)$$

Since μ/ρ is defined as the *kinematic viscosity*, ν, Eq. 16.22 can be simplified.[14]

$$\mathrm{Re} = \frac{D_e \mathrm{v}}{\nu} \qquad 16.23$$

Occasionally, the *mass flow rate per unit area*, $G = \rho \mathrm{v}$, will be known. This variable expresses the quantity of fluid flowing in $\mathrm{kg/m^2 \cdot s}$ or $\mathrm{lbm/ft^2\text{-}sec}$.

$$\mathrm{Re} = \frac{D_e G}{\mu} \quad \text{[SI]} \qquad 16.24(a)$$

$$\mathrm{Re} = \frac{D_e G}{g_c \mu} \quad \text{[U.S.]} \qquad 16.24(b)$$

11. LAMINAR FLOW

Laminar flow gets its name from the word *laminae* (layers). If all of the fluid particles move in paths parallel to the overall flow direction (i.e., in layers), the flow is said to be *laminar*. (The terms *viscous flow* and *streamline flow* are also used.) This occurs in pipeline flow when the Reynolds number is less than (approximately) 2100. Laminar flow is typical when the flow channel is small, the velocity is low, and the fluid is viscous. Viscous forces are dominant in laminar flow.

In laminar flow, a stream of dye inserted in the flow will continue from the source in a continuous, unbroken line with very little mixing of the dye and surrounding liquid. The fluid particle paths coincide with imaginary *streamlines*. (Streamlines and velocity vectors are always tangent to each other.) A "bundle" of these streamlines (i.e., a *streamtube*) constitutes a complete fluid flow.

[13]Engineering authors are not in agreement about the symbol for the Reynolds number. In addition to Re (used in this book), engineers commonly use **Re**, R, $\Re$, $\mathrm{N_{Re}}$, and $\mathrm{N_R}$.

[14]This simplification implies a caveat as well. If the viscosity is known or is given in a problem, the units must be used to determine if this viscosity is μ or ν.

12. TURBULENT FLOW

A fluid is said to be in *turbulent flow* if the Reynolds number is greater than (approximately) 4000. (This is the most common situation.) Turbulent flow is characterized by a three-dimensional movement of the fluid particles superimposed on the overall direction of motion. A stream of dye injected into a turbulent flow will quickly disperse and uniformly mix with the surrounding flow. Inertial forces dominate in turbulent flow. At very high Reynolds numbers, the flow is said to be *fully turbulent*.

13. CRITICAL FLOW

The flow is said to be in a *critical zone* or *transition region* when the Reynolds number is between 2100 and 4000. These numbers are known as the lower and upper *critical Reynolds numbers* for fluid flow, respectively. (Critical Reynolds numbers for other processes are different.) It is difficult to design for the transition region, since fluid behavior is not consistent and few processes operate in the critical zone. In the event a critical zone design is required, the conservative assumption of turbulent flow will result in the greatest value of friction loss.

14. FLUID VELOCITY DISTRIBUTION IN PIPES

With laminar flow, the viscous effects make some fluid particles adhere to the pipe wall. The closer a particle is to the pipe wall, the greater the tendency will be for the fluid to adhere to the pipe wall. The following statements characterize laminar flow.

- The velocity distribution is parabolic.
- The velocity is zero at the pipe wall.
- The velocity is maximum at the center and equal to twice the average velocity.

$$v_{ave} = \frac{\dot{V}}{A} = \frac{v_{max}}{2} \quad \text{[laminar]} \qquad 16.25$$

With turbulent flow, there is generally no distinction made between the velocities of particles near the pipe wall and particles at the pipe centerline.[15] All of the fluid particles are assumed to have the same velocity. This velocity is known as the *average* or *bulk velocity*. It can be calculated from the volume flowing.

$$v_{ave} = \frac{\dot{V}}{A} \quad \text{[turbulent]} \qquad 16.26$$

[15]This disregards the *boundary layer*, a thin layer near the pipe wall, where the velocity goes from zero to v_{ave}.

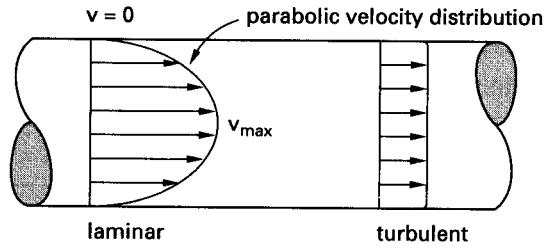


Figure 16.3 *Laminar and Turbulent Velocity Distributions*

In actuality, no flow is completely turbulent, and there is a difference between the *centerline velocity* and the average velocity. The error decreases as the Reynolds number increases. The ratio of v_{ave}/v_{max} starts at approximately 0.75 for Re = 4000 and increases to approximately 0.86 at Re = 10^6. Most problems ignore the difference between v_{ave} and v_{max}, but care should be taken when a centerline measurement (as from a pitot tube) is used to evaluate the average velocity.

For turbulent flow (Re $\approx 10^5$) in a smooth, circular pipe of radius r_o, the velocity at a radial distance r from the centerline is given by the *1/7-power law*:

$$v_r = v_{max}\left(\frac{r_o - r}{r_o}\right)^{\frac{1}{7}} \quad \text{[turbulent flow]} \qquad 16.27$$

The fluid's *velocity profile*, given by Eq. 16.27, is valid in smooth pipes up to a Reynolds number of approximately 100,000. Above that, up to a Reynolds number of approximately 400,000, an exponent of 1/8 fits experimental data better. For rough pipes, the exponent is larger (e.g., 1/5).

The ratio of the average velocity to maximum velocity is known as the *pipe coefficient* or *pipe factor*. Considering all the other coefficients used in pipe flow, these names are somewhat vague and ambiguous. Therefore, they are not in widespread use.

Equation 16.27 can be integrated to determine the average velocity.

$$v_{ave} = \left(\frac{49}{60}\right) v_{max} = 0.817 v_{max} \quad \text{[turbulent flow]} \qquad 16.28$$

When the flow is laminar, the velocity profile within a pipe will be parabolic and of the form of Eq. 16.29. (Equation 16.27 is for turbulent flow and does not describe a parabolic velocity profile.) The velocity at a radial distance r from the centerline in a pipe of radius r_o is

$$v_r = v_{max}\left(\frac{r_o - r}{r_o}\right)^2 \quad \text{[laminar flow]} \qquad 16.29$$

When the velocity profile is parabolic, the flow rate and pressure drop can easily be determined. The average velocity is half of the maximum velocity given in the velocity profile equation.

$$v_{ave} = \tfrac{1}{2} v_{max} \quad \text{[laminar flow]} \qquad 16.30$$

The average velocity is used to determine the flow quantity and friction loss. The friction loss is determined by traditional means.

$$\dot{V} = Av_{ave} \qquad 16.31$$

The kinetic energy of laminar flow can be found by integrating the velocity profile equation, resulting in Eq. 16.32.

$$E_v = v_{ave}^2 \quad \text{[laminar flow]} \quad \text{[SI]} \qquad 16.32(a)$$

$$E_v = \frac{v_{ave}^2}{g_c} \quad \text{[laminar flow]} \quad \text{[U.S.]} \qquad 16.32(b)$$

15. ENERGY GRADE LINE

The *energy grade line* (EGL) is a graph of the total energy (total specific energy) along a length of pipe.[16] In a frictionless pipe without pumps or turbines, the total specific energy is constant, and the EGL will be horizontal. (This is a restatement of the Bernoulli equation.)

$$\text{elevation of EGL} = h_p + h_v + h_z \qquad 16.33$$

The *hydraulic grade line* (HGL) is the graph of the sum of the pressure and gravitational heads, plotted as a position along the pipeline. Since the pressure head can increase at the expense of the velocity head, the HGL can increase in elevation if the flow area is increased.

$$\text{elevation of HGL} = h_p + h_z \qquad 16.34$$

The difference between the EGL and the HGL is the velocity head, h_v, of the fluid.

$$h_v = \text{elevation of EGL} - \text{elevation of HGL} \qquad 16.35$$

The following rules apply to these grade lines in a frictionless environment without pumps or turbines.

- The EGL is always horizontal.
- The HGL is always equal to or below the EGL.
- For still ($v = 0$) fluid at a free surface, EGL = HGL (i.e., the EGL coincides with the fluid surface in a reservoir).
- If flow velocity is constant (i.e., flow in a constant-area pipe), the HGL will be horizontal and parallel to the EGL, regardless of pipe orientation or elevation.
- When the flow area decreases, the HGL decreases.
- When the flow area increases, the HGL increases.
- In a free jet (i.e., a stream of water from a hose), the HGL coincides with the jet elevation, following a parabolic path.

[16]The term *energy line* (EL) is also used.

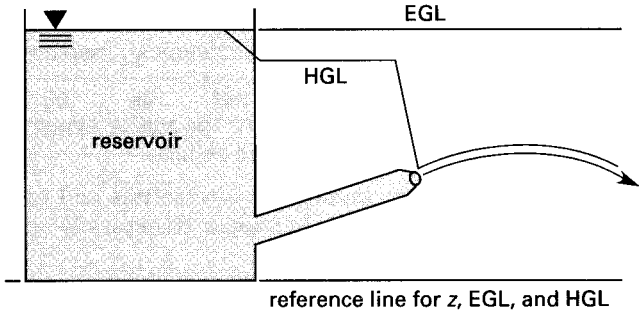

Figure 16.4 *Energy and Hydraulic Grade Lines Without Friction*

16. SPECIFIC ENERGY

Specific energy is a term that is used primarily with open channel flow. It is the total energy with respect to the channel bottom, consisting of pressure and velocity energy terms only.

$$E_{specific} = E_p + E_v \qquad 16.36$$

Since the channel bottom is chosen as the reference elevation ($z = 0$) for gravitational energy, there is no contribution by gravitational energy to specific energy.

$$E_{specific} = \frac{p}{\rho} + \frac{v^2}{2} \quad \text{[SI]} \qquad 16.37(a)$$

$$E_{specific} = \frac{p}{\rho} + \frac{v^2}{2g_c} \quad \text{[U.S.]} \qquad 16.37(b)$$

However, since p is the hydrostatic pressure at the channel bottom due to a fluid depth, d, p/ρ can be interpreted as the depth of the fluid.

$$h_{specific} = d + \frac{v^2}{2g} \qquad 16.38$$

Specific energy is constant when the flow depth and width are constant (i.e., *uniform flow*). A change in channel width will cause a change in flow depth, and since width is not part of the equation for specific energy, there will be a corresponding change in specific energy. There are other ways that specific energy can decrease, also.[17]

17. PIPE MATERIALS AND SIZES

Many materials are used for pipes. The material used depends on the application. Water supply distribution, wastewater collection, and air conditioning refrigerant lines all place different demands on pipe material performance. Pipe materials are chosen on the basis of strength to withstand internal pressures, strength

[17]Specific energy changes dramatically in a *hydraulic jump* or *hydraulic drop*.

to withstand external loads from backfill and traffic, smoothness, corrosion resistance, chemical inertness, cost, and other factors.

The following are characteristics of the major types of commercial pipe materials that are in use.

- *asbestos cement*: immune to electrolysis and corrosion, light in weight but weak structurally; environmentally limited
- *concrete*: durable, water-tight, low maintenance, smooth interior
- *copper and brass*: used primarily for water, condensate, and refrigerant lines; in some cases, easily bent by hand, good thermal conductivity
- *ductile cast iron*: long-lived, strong, impervious, heavy, scour-resistant, but costly
- *plastic* (PVC and ABS):[18] chemically inert, resistant to corrosion, very smooth, lightweight, low cost
- *steel*: high strength, ductile, resistant to shock, very smooth interior, but susceptible to corrosion
- *vitrified clay*: resistant to corrosion, acids (e.g., hydrogen sulfide from septic sewage), scour, and erosion

Table 16.2 lists recommendations for pipe materials in several common applications.

Table 16.2 *Recommended Pipe Materials by Application*

service	pipe material
most refrigerants (suction, liquid, and hot gas lines)	hard copper tubing (type L);[a] standard wall steel pipe, lap-welded or seamless
chilled water	hard copper tubing; plain (black) or galvanized steel pipe[b]
condenser or quad make-up water	hard copper tubing; plain or galvanized steel pipe[b]
steam or condensate	hard copper tubing; steel pipe[b]
hot water	hard copper tubing; steel pipe

[a]Soft copper may be used for $^1/_4$ in (6.3 mm) and $^3/_8$ in (9.5 mm) (outside diameter) with wall thicknesses of 0.30 in (7.6 mm) and 0.32 in (8.1 mm), respectively. Soft copper refrigeration lines are commonly used up to $1^3/_8$ in (35 mm) (outside diameter). Mechanical joints should not be used with soft copper tubing larger than $^7/_8$ in (22 mm).

[b]Standard wall steel pipe or type-M hard copper tubing are usually satisfactory for air conditioning applications. However, the pressure rating of the pipe material should be checked at the design temperature.

The required wall thickness of a pipe is proportional to the pressure the pipe must carry. However, not all pipes operate at high pressures. Therefore, pipes and tubing may be available in different wall thicknesses (*schedules, series,* or *types*). Steel pipe, for example, is available in schedules 40, 80, and others.[19]

For initial estimates, the approximate schedule of steel pipe can be calculated from Eq. 16.39. p is the operating pressure in psig; S is the allowable stress in the pipe material; and E is the *joint efficiency*, also known as the *joint quality factor* (typically 1.00 for seamless pipe, 0.85 for electric resistance-welded pipe, 0.80 for electric fusion-welded pipe, and 0.60 for furnace butt-welded pipe). For seamless carbon steel (A53) pipe used below 650°F (340°C), the allowable stress is approximately 12,000 to 15,000 psi. So, with butt-welded joints, a value of 6500 psi is often used for the product SE.

$$\text{schedule} \approx \frac{1000p}{SE} \qquad 16.39$$

Steel pipe is available in black (i.e., plain) and galvanized (inside, outside, or both) varieties. Steel pipe is manufactured in plain-carbon and stainless varieties. AISI 316 stainless is particularly corrosion resistant.

The actual dimensions of some pipes (concrete, clay, some cast iron, etc.) coincide with their *nominal dimensions*. For example, a 12 in concrete pipe has an inside diameter of 12 in, and no further refinement is needed. However, some pipes and tubing (e.g., steel pipe, copper and brass tubing, and some cast iron) are called out by a nominal diameter that has nothing to do with the internal diameter of the pipe. For example, a 16 in schedule-40 steel pipe has an actual inside diameter of 15 in. In some cases, the nominal size does not coincide with the external diameter, either.

PVC (polyvinyl chloride) pipe is used extensively as water and sewer pipe due to its combination of strength, ductility, and corrosion resistance. Manufactured lengths are approximately 10 to 13 ft (3 to 3.9 m) for sewer pipe and 20 ft (6 m) for water pipe, with integral gasketed joints or solvent-weld bells. Infiltration is very low (less than 50 gal/in-mile-day), even in the wettest environments. The low Manning's roughness constant (0.009 typical) allows PVC sewer pipe to be used with flatter grades or smaller diameters. PVC pipe is resistant to corrosive soils and sewerage gases and is generally resistant to abrasion from pipe-cleaning tools.

It is essential that tables of pipe sizes, such as App. 16.B, be used when working problems involving steel and copper pipes since there is no other way to obtain the inside diameters of such pipes.[20]

[18]PVC: polyvinyl chloride; ABS: acrylonitrile-butadiene-styrene.

[19]Other schedules of steel pipe, such as 30, 60, 120, etc., also exist, but in limited sizes, as Table 16.3 indicates. Schedule-40 pipe roughly corresponds to the standard weight (S) designation used in the past. Schedule-80 roughly corresponds to the extra-strong (X) designation. There is no uniform replacement for double-extra-strong (XX) pipe.

[20]It is a characteristic of standard steel pipes that the schedule number does not affect the outside diameter of the pipe. An 8 in schedule-40 pipe has the same exterior dimensions as an 8 in schedule-80 pipe. However, the interior flow area will be less for the schedule-80 pipe.

Table 16.3 *Dimensions of Commercial Steel Pipe*[a] *(English Units)*

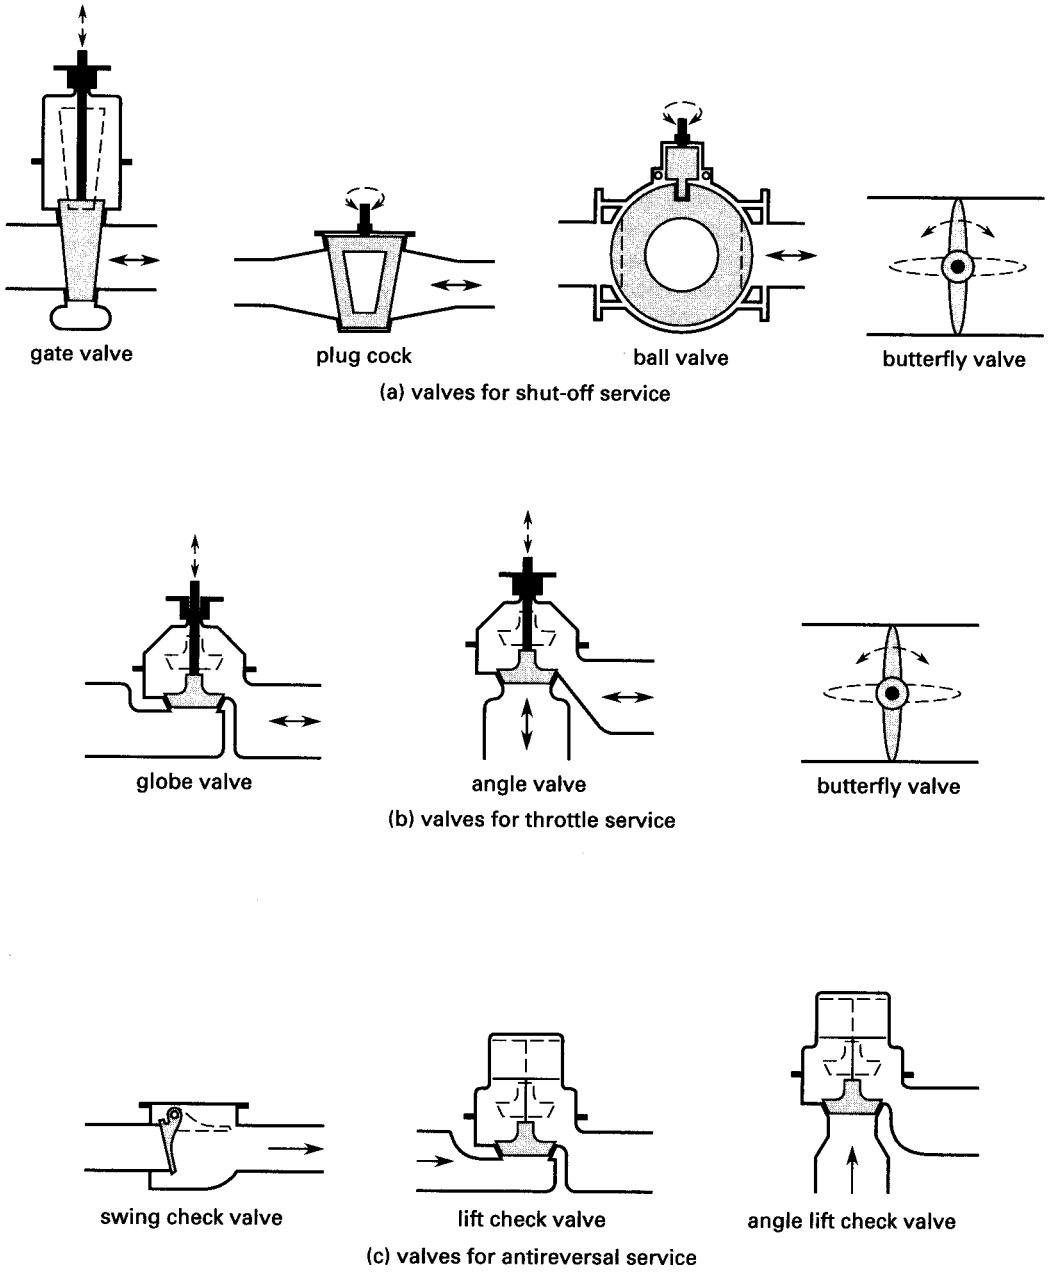
18. MANUFACTURED PIPE STANDARDS

There are many different standards governing pipe diameters and wall thicknesses. A pipe's nominal outside diameter is rarely sufficient to determine the internal dimensions of the pipe. A manufacturing specification and class or category are usually needed to completely specify pipe dimensions.



Cast iron and ductile iron (CI/DI) pipes are produced to AWWA C151 standards. Gasketed PVC sewer pipe up to 15 in inside diameter are produced to ASTM D3034 standards. Gasketed sewer PVC pipe from 18 in to 28 in are produced to ASTM F679 standards. PVC pressure pipe for water distribution is manufactured to AWWA C900 standards. Truss pipe is manufactured to ASTM D2680 standards. Reinforced concrete pipe (RCP) is manufactured to ASTM C76 standards.

19. PAINTS, COATINGS, AND LININGS

Various materials are used to protect steel and ductile iron pipes against rust and other forms of corrosion. *Red primer* is a shop-applied rust inhibiting primer applied to prevent short-term rust prior to shipment and the application of subsequent coatings. *Asphaltic coating* ("tar" coating) is applied to the exterior of underground pipes. *Bituminous coating* refers to a similar coating made from tar pitch. Both asphaltic and bituminous coatings should be completely removed or sealed with a synthetic resin prior to the pipe being finish-coated, since their oils may bleed through otherwise.

Though bituminous materials (i.e., asphaltic materials) continue to be cost effective, epoxy-based products are now extensively used. Epoxy products are delivered as a two-part formulation (a polyamide resin and liquid chemical hardener) that is mixed together prior to application. *Coal tar epoxy*, also referred to as *epoxy coal tar*, a generic name, sees frequent use in pipes exposed to high humidity, seawater, other salt solutions, and crude oil. Though suitable for coating steel penstocks of hydroelectric installations, coal tar epoxy is generally not suitable for potable water delivery systems. Though it is self-priming, appropriate surface preparation is required for adequate adhesion. It has a density of 1.9 to 2.3 lbm/gal (230 to 280 g/L).

Figure 16.5 *Types of Valves*

20. TYPES OF VALVES

Valves used for *shutoff service* (e.g., gate, plug, ball, and butterfly valves) are used fully open or fully closed. *Gate valves* offer minimum resistance to flow. They are used in clean fluid and slurry services when valve operation is infrequent. Many turns of the handwheels are required to raise or lower their gates. *Plug valves* provide for tight shutoff. A 90° turn of their handles is sufficient to rotate the plugs fully open or closed. *Ball valves* offer an unobstructed flow path and tight shutoff. They are often used with slurries and viscous fluids, as well as with cryogenic fluids. A 90° turn of their handles rotates the balls fully open or closed. *Butterfly valves* (when specially designed with appropriate seats) can be used for shutoff operation. They are particularly applicable to large flows of low-pressure (vacuum up to 150 psig (1 MPa)) gases or liquids. Their straight-through, open-disk design results in minimal solids build-up and low pressure drops.

Other valve types (e.g., globe, needle, Y-, angle, and butterfly valves) are more suitable for *throttling service. Globe valves* provide positive shutoff and precise metering on clean fluids. However, since the seat is parallel to the direction of flow and the fluid makes two right-angle turns, there is substantial resistance and pressure drop through them, as well as relatively fast erosion of the seat. Globe valves are intended for infrequent operation. *Needle valves* are similar to globe valves, except that the plug is a tapered, needle-like cone. Needle valves provide accurate metering of small flows of clean fluids. Needle valves are applicable to cryogenic fluids. *Y-valves* are similar to globe valves in operation, but their seats are inclined to the direction of flow, offering more of a straight-through passage and unobstructed flow than the globe valve. *Angle valves* are essentially globe valves where the fluid makes a 90° turn. They can be used for throttling and shut-off of clean or viscous fluids and slurries. *Butterfly valves* are often used for throttling services with the same limitations and benefits as those listed for shutoff use.

Other valves are of the *check* (*nonreverse-flow*) variety. These react automatically to changes in pressure to prevent reversals of flow. Special check valves can also prevent excess flow. Figure 16.5 illustrates *swing, lift,* and *angle lift check valves.*

PRACTICE PROBLEMS

Use the following values unless told to do otherwise in the problem:

$$g = 32.2 \text{ ft/sec}^2 \ (9.81 \text{ m/s}^2)$$
$$\rho_{\text{water}} = 62.4 \text{ lbm/ft}^3 \ (1000 \text{ kg/m}^3)$$
$$p_{\text{atmospheric}} = 14.7 \text{ psia } (101.3 \text{ kPa})$$

Hydraulic Radius

1. A 10 in (25 cm) composition pipe is compressed by a tree root until its inside height is only 7.2 in (18 cm). What is its approximate hydraulic radius when flowing half full? State your assumptions.

(A) 2.2 in (5.5 cm)
(B) 2.7 in (6.9 cm)
(C) 3.2 in (8.1 cm)
(D) 4.5 in (11.4 cm)

The answer is (A).

2. A pipe with an inside diameter of 18.812 in contains water to a depth of 15.7 in. What is the hydraulic radius? (Work in customary U.S. units only.)

(A) 4.39 in
(B) 5.08 in
(C) 5.72 in
(D) 6.51 in

The answer is (C).

Table 16.4 *Characteristics of Common Valve Types*

valve type	fluid condition	switching frequency	pressure drop (fully open)	control response	maximum pressure, atm	maximum temperature, °C
ball	clean	low	low	very poor	160	300
butterfly	clean	low	low	poor	50	400
diaphragm	clean to slurried	very high	low to medium	very good	16	150
gate	clean	low	low	very poor	50	400
globe	clean	high	medium to high	very good	80	300
plug	clean	low	low	very poor	160	300

1. HYDRAULICS AND HYDRODYNAMICS

This chapter investigates fluid moving through pipes, measurements with venturis and orifices, and other motion-related topics such as model theory, lift and drag, and pumps. In a strict interpretation, any fluid-related phenomenon that is not hydro*statics* should be hydro*dynamics*. However, tradition has separated the study of moving fluids into the fields of hydraulics and hydrodynamics.

In a general sense, *hydraulics* is the study of the practical laws of fluid flow and resistance in pipes and open channels. Hydraulic formulas are often developed from experimentation, empirical factors, and curve fitting, without an attempt to justify why the fluid behaves the way it does.

On the other hand, *hydrodynamics* is the study of fluid behavior based on theoretical considerations. Hydrodynamicists start with Newton's laws of motion and try to develop models of fluid behavior. Models developed in this manner are complicated greatly by the inclusion of viscous friction and compressibility. Therefore, hydrodynamic models assume a perfect fluid with constant density and zero viscosity. The conclusions reached by hydrodynamicists can differ greatly from those reached by hydraulicians.[1]

2. CONSERVATION OF MASS

Fluid mass is always conserved in fluid systems, regardless of the pipeline complexity, orientation of the flow, or which fluid is flowing. This single concept is often sufficient to solve simple fluid problems.

$$\dot{m}_1 = \dot{m}_2 \qquad 17.1$$

When applied to fluid flow, the conservation of mass law is known as the *continuity equation.*

$$\rho_1 A_1 \mathrm{v}_1 = \rho_2 A_2 \mathrm{v}_2 \qquad 17.2$$

If the fluid is incompressible, then $\rho_1 = \rho_2$.

$$A_1 \mathrm{v}_1 = A_2 \mathrm{v}_2 \qquad 17.3$$

$$\dot{V}_1 = \dot{V}_2 \qquad 17.4$$

Various units and symbols are used for *volumetric flow rate.* (Though this book uses $\dot{V}$, the symbol Q is often used when the flow rate is expressed in gallons.)

[1] Perhaps the most disparate conclusion is *D'Alembert's paradox.* In 1744, D'Alembert derived theoretical results "proving" that there is no resistance to bodies moving through an ideal (non-viscous) fluid.

MGD (millions of gallons per day) and mgpcd (millions of gallons per capita day) are units commonly used in municipal water works problems. MMSCFD (millions of standard cubic feet per day) may be used to express gas flows.

Calculation of flow rates is often complicated by the interdependence between flow rate and friction loss. Each affects the other. Hence, many pipe flow problems must be solved iteratively. Usually, a reasonable friction factor is assumed and is used to calculate an initial flow rate. The flow rate establishes the flow velocity, from which a revised friction factor can be determined.

3. MAXIMUM VELOCITIES IN PIPES

Fluid friction in pipes is kept at acceptable levels by maintaining reasonable fluid velocities. Table 17.1 lists typical maximum fluid velocities.

Table 17.1 *Typical Maximum Fluid Velocities*

	maximum velocity	
fluid and application	ft/sec	m/s
water: city service	2–5	0.6–1.5
water: boiler feed	10	3
air: compressor suction	75–200	23–60
air: compressor discharge	100–250	30–75
refrigerant: suction	15–35	4.5–11
refrigerant: discharge	35–60	11–18
steam, saturated: heating	65–100	20–30
steam, saturated: miscellaneous	100–200	30–60
steam, superheated: turbine feed	160–250	50–75

4. STREAM POTENTIAL AND STREAM FUNCTION

An application of hydrodynamic theory is the derivation of the stream function from stream potential. The *stream potential function (velocity potential function)*, Φ, is the algebraic sum of the component velocity potential functions.[2]

$$\Phi = \Phi_x(x,y) + \Phi_y(x,y) \qquad 17.5$$

The velocity component of the resultant in the x-direction is

$$u = \frac{\partial \Phi}{\partial x} \qquad 17.6$$

[2]The two-dimensional derivation of the stream function can be extended to three dimensions, if necessary. The stream function can also be expressed in the cylindrical coordinate system.

The velocity component of the resultant in the y-direction is

$$v = \frac{\partial \Phi}{\partial y} \qquad 17.7$$

The total derivative of the stream potential function is

$$\begin{aligned} d\Phi &= \frac{\partial \Phi}{\partial x}dx + \frac{\partial \Phi}{\partial y}dy \\ &= u\,dx + v\,dy \end{aligned} \qquad 17.8$$

An *equipotential line* is a line along which the function Φ is constant (i.e., $d\Phi = 0$). The slope of the equipotential line is derived from Eq. 17.8.

$$\left.\frac{dy}{dx}\right|_{\text{equipotential}} = -\frac{u}{v} \qquad 17.9$$

For flow through a porous, permeable medium, pressure will be constant along equipotential lines (i.e., along lines of constant Φ). However, for an ideal, nonviscous fluid flowing in a frictionless environment, Φ has no physical significance. Even though Φ has a theoretical basis, it does not coincide with any measurable physical quantity.

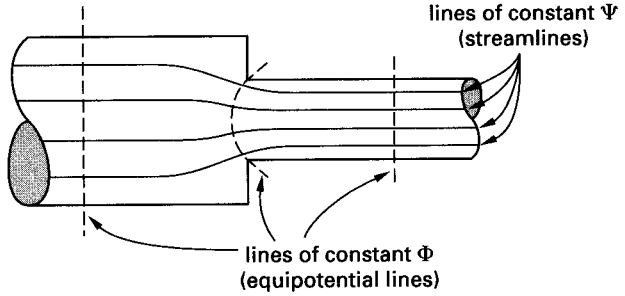

Figure 17.1 *Equipotential Lines and Streamlines*

The *stream function (Lagrange stream function)*, $\Psi(x,y)$, defines the direction of flow at a point.

$$u = \frac{\partial \Psi}{\partial y} \qquad 17.10$$

$$v = -\frac{\partial \Psi}{\partial x} \qquad 17.11$$

The stream function can also be written in total derivative form.

$$\begin{aligned} d\Psi &= \frac{\partial \Psi}{\partial x}dx + \frac{\partial \Psi}{\partial y}dy \\ &= -v\,dx + u\,dy \end{aligned} \qquad 17.12$$

The stream function, $\Psi(x,y)$, satisfies Eq. 17.12. For a given streamline, $d\Psi = 0$, and each streamline is a line representing a constant value of Ψ. A streamline is perpendicular to an equipotential line.

$$\left.\frac{dy}{dx}\right|_{\text{streamline}} = \frac{v}{u} \qquad 17.13$$

Example 17.1

The stream potential function for water flowing through a particular valve is

$$\Phi = 3xy - 2y$$

What is the stream function, Ψ?

Solution

First, work with Φ to obtain u and v.

$$u = \frac{\partial\Phi}{\partial x} = \frac{\partial(3xy - 2y)}{\partial x} = 3y$$
$$v = \frac{\partial\Phi}{\partial y} = 3x - 2$$

u and v are also related to the stream function, Ψ. From Eq. 17.10,

$$u = \frac{\partial\Psi}{\partial y}$$
$$\partial\Psi = u\,\partial y$$
$$\Psi = \int 3y\,dy = \tfrac{3}{2}y^2 + \text{ some function of } x + C_1$$

Similarly, from Eq. 17.11,

$$v = -\frac{\partial\Psi}{\partial x}$$
$$\partial\Psi = -v\,\partial x$$
$$\Psi = -\int (3x - 2)\,dx$$
$$= 2x - \tfrac{3}{2}x^2 + \text{ some function of } y + C_2$$

Ψ is found by superposition of these two results.

$$\Psi = \tfrac{3}{2}y^2 + 2x - \tfrac{3}{2}x^2 + C$$

5. HEAD LOSS DUE TO FRICTION

The original Bernoulli equation was based on an assumption of frictionless flow. In actual practice, friction occurs during fluid flow. This friction "robs" the fluid of energy, so that the fluid at the end of a pipe section has less energy than it does at the beginning.[3]

$$E_1 > E_2 \qquad 17.14$$

[3]The friction generates minute amounts of heat. The heat is lost to the surroundings.

Most formulas for calculating friction loss use the symbol h_f to represent the *head loss due to friction*.[4] This loss is added into the original Bernoulli equation to restore the equality. Of course, the units of h_f must be the same as the units for the other terms in the Bernoulli equation. If the Bernoulli equation is written in terms of energy, the units will be ft-lbf/lbm or J/kg.

$$E_1 = E_2 + E_f \qquad 17.15$$

Consider the constant-diameter, horizontal pipe in Fig. 17.2. An incompressible fluid is flowing at a steady rate. Since the elevation of the pipe does not change, the potential energy is constant. Since the pipe has a constant area, the kinetic energy (velocity) is constant. Therefore, the friction energy loss must show up as a decrease in pressure energy. Since the fluid is incompressible, this can only occur if the pressure decreases in the direction of flow.

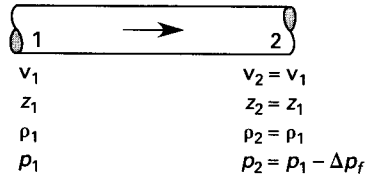

Figure 17.2 *Pressure Drop in a Pipe*

6. RELATIVE ROUGHNESS

It is intuitive that pipes with rough inside surfaces will experience greater friction losses than smooth pipes.[5] *Specific roughness*, ϵ, is a parameter that measures the average size of imperfections inside the pipe. Table 17.2 lists values of ϵ for common pipe materials. (Also, see App. 17.A.)

Table 17.2 *Values of Specific Roughness for Common Pipe Materials*

material	ϵ, ft	ϵ, m
plastic (PVC, ABS)	0.000005	1.5×10^{-6}
copper and brass	0.000005	1.5×10^{-6}
steel	0.0002	6.0×10^{-5}
plain cast iron	0.0008	2.4×10^{-4}
concrete	0.004	1.2×10^{-3}

[4]Other names and symbols for this friction loss are *friction head loss* (h_L), *lost work* (LW), *friction heating* ($\mathcal{F}$), *skin friction loss* (F_f), and *pressure drop due to friction* (Δp_f). All terms and symbols mean basically the same thing, although the units may need to be converted.

[5]Surprisingly, this intuitive statement is valid only for turbulent flow. The roughness does not (ideally) affect the friction loss for laminar flow.

However, an imperfection the size of a sand grain will have much more effect in a small-diameter hydraulic line than in a large-diameter sewer. Therefore, the *relative roughness*, ϵ/D, is a better indicator of pipe roughness. Both ϵ and D have units of length (e.g., feet or meters), and the relative roughness is dimensionless.

7. FRICTION FACTOR

The *Darcy friction factor*, f, is one of the parameters used to calculate friction loss.[6] The friction factor is not constant, but decreases as the Reynolds number (fluid velocity) increases, up to a certain point known as *fully turbulent flow* (or *rough-pipe flow*). Once the flow is fully turbulent, the friction factor remains constant and depends only on the relative roughness and not on the Reynolds number. For very smooth pipes, fully turbulent flow is achieved only at very high Reynolds numbers.

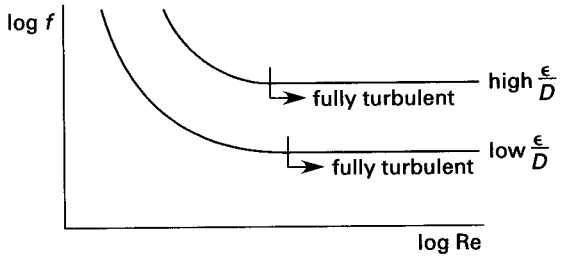

Figure 17.3 *Friction Factor as a Function of Reynolds Number*

The friction factor is not dependent on the material of the pipe but is affected by the roughness. For example, for a given Reynolds number, the friction factor will be the same for any smooth pipe material (glass, plastic, smooth brass and copper, etc.).

The friction factor is determined from the relative roughness, ϵ/D, and the Reynolds number, Re, by various methods. These methods include explicit and implicit equations, the Moody diagram, and tables. The values obtained are based on experimentation, primarily the work of J. Nikuradse in the early 1930s.

When a moving fluid initially encounters a parallel surface (as when a moving gas encounters a flat plate or when a fluid first enters the mouth of a pipe), the flow will generally not be turbulent, even for very rough surfaces. The flow will be laminar for a certain *critical distance* before becoming turbulent.

[6]There are actually two friction factors: the Darcy friction factor and the *Fanning friction factor*, f_{Fanning}, also known as the *skin friction coefficient* and *wall shear stress factor*. Both factors are in widespread use, sharing the same symbol, f. Civil and (most) mechanical engineers use the Darcy friction factor. The Fanning friction factor is encountered more often in the chemical industry. One can be derived from the other: $f_{\text{Darcy}} = 4f_{\text{Fanning}}$.

Friction Factors for Laminar Flow

The easiest method of obtaining the friction factor for laminar flow (Re < 2100) is to calculate it. Equation 17.16, known as the *Darcy equation*, illustrates that roughness is not a factor in determining the frictional loss in ideal laminar flow.

$$f = \frac{64}{\text{Re}} \qquad 17.16$$

Friction Factors for Turbulent Flow: by Formula

One of the earliest attempts to predict the friction factor for turbulent flow in smooth pipes resulted in the *Blasius equation* (claimed "valid" for $3000 < \text{Re} < 100{,}000$).

$$f = \frac{0.316}{\text{Re}^{0.25}} \qquad 17.17$$

The *Nikuradse equation* can also be used to determine the friction factor for smooth pipes (i.e., when $\epsilon/D = 0$). Unfortunately, this equation is implicit in f and must be solved iteratively.

$$\frac{1}{\sqrt{f}} = 2.0\ \log_{10}\left(\text{Re}\sqrt{f} - 0.80\right) \qquad 17.18$$

The *Karman-Nikuradse equation* predicts the fully turbulent friction factor (i.e., when Re is very large).

$$\frac{1}{\sqrt{f}} = 1.74 - 2\ \log_{10}\left(\frac{2\epsilon}{D}\right) \qquad 17.19$$

The most widely known method of calculating the friction factor for any pipe roughness and Reynolds number is another implicit formula, the *Colebrook equation*. Most other equations are variations of this equation. (Notice that the relative roughness, ϵ/D, is used to calculate f.)

$$\frac{1}{\sqrt{f}} = -2\ \log_{10}\left(\frac{\frac{\epsilon}{D}}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}}\right) \qquad 17.20$$

A suitable approximation would appear to be the Swamee-Jain equation, which claims to have less than 1% error (as measured against the Colebrook equation) for relative roughnesses between 0.000001 and 0.01, and for Reynolds numbers between 5000 and 100,000,000.[7] Even with a 1% error, this equation produces more accurate results than can be read from the Moody diagram.

$$f = \frac{0.25}{\left[\log_{10}\left(\frac{\frac{\epsilon}{D}}{3.7} + \frac{5.74}{\text{Re}^{0.9}}\right)\right]^2} \qquad 17.21$$

[7]*ASCE Hydraulic Division Journal*, Vol. 102, May 1976, p. 657. This is not the only explicit approximation to the Colebrook equation in existence.

Friction Factors for Turbulent Flow: by Moody Chart

The *Moody friction factor chart*, Fig. 17.4, presents the friction factor graphically as a function of Reynolds number and relative roughness. There are different lines for selected discrete values of relative roughness. Due to the complexity of this graph, it is easy to mislocate the Reynolds number or use the wrong curve. Nevertheless, the Moody chart remains the most common method of obtaining the friction factor.

Friction Factors for Turbulent Flow: by Table

Appendix 17.B (based on the Colebrook equation), or a similar table, will usually be the most convenient method of obtaining friction factors for turbulent flow.

Example 17.2

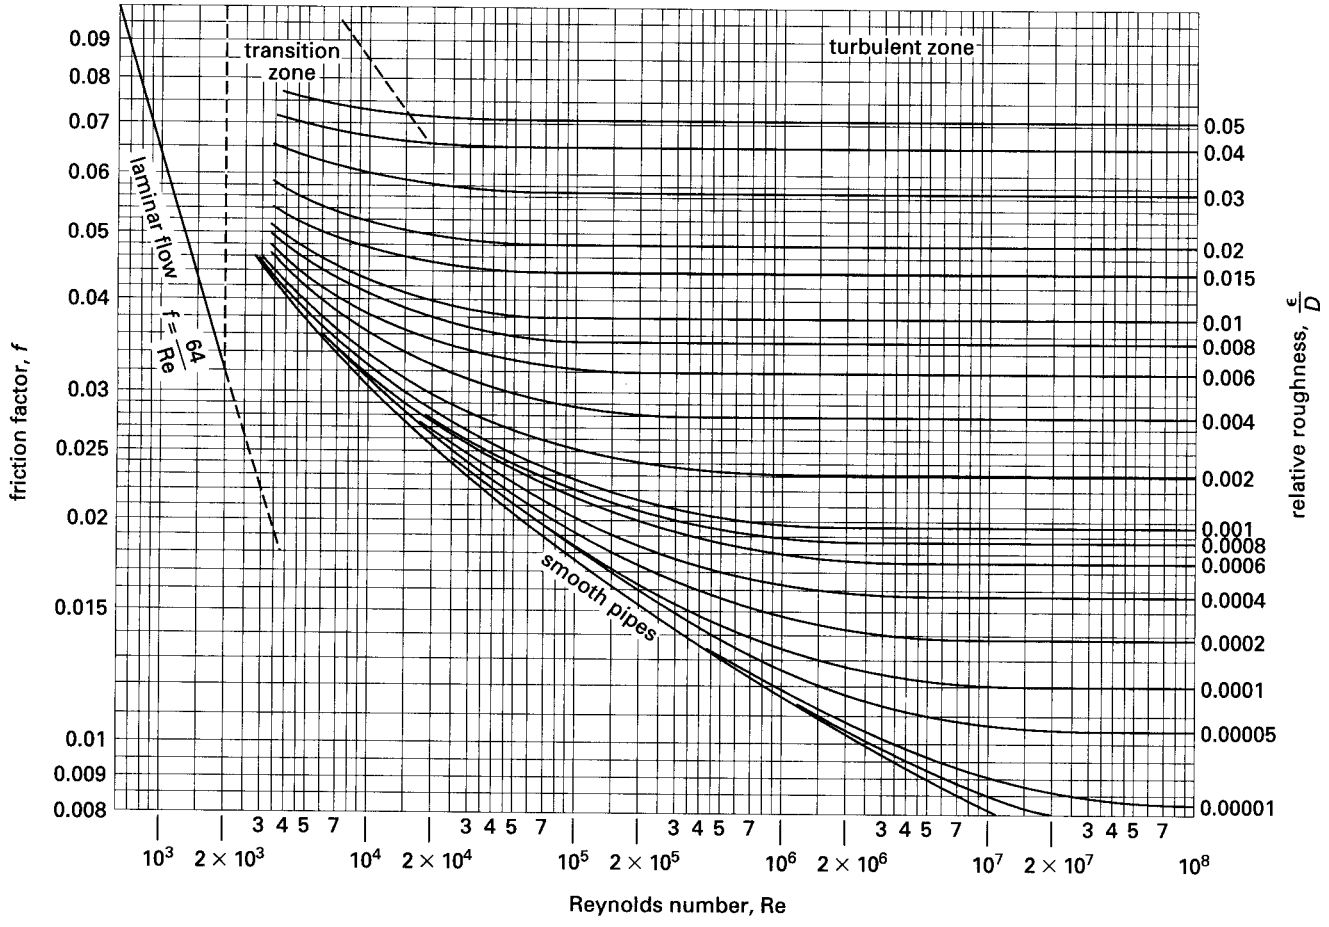
Determine the friction factor for a Reynolds number of Re = 400,000 and a relative roughness of $\epsilon/D = 0.004$ using (a) the Moody diagram, (b) App. 17.B, and (c) the Swamee-Jain approximation. (d) Check the table value of f with the Colebrook equation.

Solution

(a) From Fig. 17.4, the friction factor is approximately 0.028.

(b) Appendix 17.B lists the friction factor as 0.0287.

(c) From Eq. 17.21,



$$f = \frac{0.25}{\left[\log_{10}\left(\frac{0.004}{3.7} + \frac{5.74}{(400{,}000)^{0.9}}\right)\right]^2}$$

$$= 0.0288$$

(d) From Eq. 17.20,

$$\frac{1}{\sqrt{0.0287}} = -2\ \log_{10}\left(\frac{0.004}{3.7} + \frac{2.51}{(400{,}000)\sqrt{0.0287}}\right)$$

$$5.903 = 5.903$$

Figure 17.4 *Moody Friction Factor Chart*

8. ENERGY LOSS DUE TO FRICTION: LAMINAR FLOW

Two methods are available for calculating the frictional energy loss for fluids experiencing laminar flow. The most common is the *Darcy equation* (also known as the *Weisbach equation* or the *Darcy-Weisbach equation*), which can be used for both laminar and turbulent flow.[8] One of the advantages to using the Darcy equation is that the assumption of laminar flow does not need to be confirmed if f is known.

$$h_f = \frac{fLv^2}{2Dg} \qquad 17.22$$

$$E_f = h_f g = \frac{fLv^2}{2D} \qquad \text{[SI]} \quad 17.23(a)$$

$$E_f = h_f \times \left(\frac{g}{g_c}\right) = \frac{fLv^2}{2Dg_c} \qquad \text{[U.S.]} \quad 17.23(b)$$

If the flow is truly laminar and the fluid is flowing in a circular pipe, then the *Hagen-Poiseuille equation* can be used.

$$E_f = \frac{32\mu vL}{D^2\rho} \qquad \text{[SI]} \quad 17.24(a)$$

$$E_f = \frac{32\mu vLg_c}{D^2\rho} \qquad \text{[U.S.]} \quad 17.24(b)$$

An alternate form of the Hagen-Poiseuille equation substitutes $\dot{V}/A$ for v.

$$E_f = \frac{128\mu\dot{V}L}{\pi D^4\rho} \qquad \text{[SI]} \quad 17.25(a)$$

$$E_f = \frac{128\mu\dot{V}Lg_c}{\pi D^4\rho} \qquad \text{[U.S.]} \quad 17.25(b)$$

If necessary, h_f can be converted to an actual pressure drop in psi or Pa by multiplying by the fluid density.

$$\Delta p = h_f \times \rho g \qquad \text{[SI]} \quad 17.26(a)$$

$$\Delta p = h_f \times \rho\left(\frac{g}{g_c}\right) \qquad \text{[U.S.]} \quad 17.26(b)$$

Values of the Darcy friction factor, f, are often quoted for new, clean pipe. The friction head losses and pumping power requirements calculated from these values are minimal values. Depending on the nature of the service, scale and impurity buildup within pipes may decrease the pipe diameters over time. Since the frictional loss is proportional to the fifth power of the diameter, such diameter decreases can produce dramatic increases in the friction loss.

$$\frac{h_{f,\text{scaled}}}{h_{f,\text{new}}} = \left(\frac{D_{\text{new}}}{D_{\text{scaled}}}\right)^5 \qquad 17.27$$

[8]The difference is that the friction factor can be derived by hydrodynamics: $f = 64/\text{Re}$. For turbulent flow, f is empirical.

Equation 17.27 accounts only for the decrease in diameter. Any increase in roughness (i.e., friction factor) will produce a proportional increase in friction loss.

Because the "new, clean" condition is transitory in most applications, an uprating factor of 10 to 30% is often applied to either the friction factor, f, or the head loss, h_f. Of course, even larger increases should be considered when extreme fouling is expected.

Another approach eliminates the need to estimate the scaled pipe diameter. This simplistic approach multiplies the initial friction loss by a factor based on the age of the pipe. For example, for schedule-40 pipe 4 to 10 in (10 to 25 cm) in diameter, the multipliers of 1.4, 2.2, and 5.0 have been proposed for pipe ages of 5, 10, and 20 years, respectively. For larger pipes, the corresponding multipliers are 1.3, 1.6, and 2.0. Obviously, use of these values should be based on a clear understanding of the method's limitations.

9. ENERGY LOSS DUE TO FRICTION: TURBULENT FLOW

The *Darcy equation* is used almost exclusively to calculate the head loss due to friction for turbulent flow.

$$h_f = \frac{fLv^2}{2Dg} \qquad 17.28$$

The head loss can be converted to pressure drop.

$$\Delta p = h_f \times \rho g \qquad \text{[SI]} \quad 17.29(a)$$

$$\Delta p = h_f \times \rho\left(\frac{g}{g_c}\right) \qquad \text{[U.S.]} \quad 17.29(b)$$

In problems where the pipe size is unknown, it will be impossible to obtain an accurate initial value of the friction factor, f (since f depends on velocity). In such problems, an iterative solution will be necessary.

It is not uncommon for civil engineers to use the *Hazen-Williams equation* to calculate head loss. This method requires knowledge of the Hazen-Williams *roughness coefficient*, C, values of which are widely tabulated.[9] (See App. 17.A.) The advantage of using this equation is that C does not depend on the Reynolds number.

$$h_f = \frac{(3.022)(\text{v})^{1.85}L}{(C)^{1.85}(D)^{1.165}} \qquad \text{[U.S.]} \quad 17.30$$

Or, in terms of other units,

$$h_f = \frac{(10.44)(L)(\dot{V}_{\text{gpm}})^{1.85}}{(C)^{1.85}(d_{\text{inches}})^{4.8655}} \qquad \text{[U.S.]} \quad 17.31$$

[9]An approximate value of $C = 140$ is often chosen for initial calculations for new water pipe. $C = 100$ is more appropriate for water pipe that has been in service for some time. For sludge, C values are 20 to 40% lower than the equivalent water pipe values.

The Hazen-Williams equation is empirical and is not dimensionally homogeneous. It is taken as a matter of faith that the units of h_f are feet.

The Hazen-Williams equation should be used only for turbulent flow. It gives good results for liquids that have kinematic viscosities around 1.2×10^{-5} ft^2/sec (1.1×10^{-6} m^2/s), which corresponds to the viscosity of 60°F (16°C) water. At extremely high and low temperatures, the Hazen-Williams equation can be 20% or more in error for water.

Example 17.3

50°F water is pumped through 1000 ft of 4 in, schedule-40 welded steel pipe at the rate of 300 gpm. What friction loss (in ft-lbf/lbm) is predicted by the Darcy equation?

Solution

First, it is necessary to collect data on the pipe and water. The fluid viscosity, pipe dimensions, and other parameters can be found from the appendices.

$$\nu = 1.41 \times 10^{-5} \text{ ft}^2/\text{sec} \quad \text{[App. 14.A]}$$

$$\epsilon = 0.0002 \text{ ft} \quad \text{[App. 17.A]}$$

$$D = 0.3355 \text{ ft} \quad \text{[App. 16.B]}$$

$$A = 0.0884 \text{ ft}^2 \quad \text{[App. 16.B]}$$

The flow quantity is converted from gallons per minute to cubic feet per second.

$$\dot{V} = (300 \text{ gpm}) \left(0.002228 \frac{\frac{\text{ft}^3}{\text{sec}}}{\text{gpm}} \right) = 0.6684 \text{ ft}^3/\text{sec}$$

The velocity is

$$\text{v} = \frac{\dot{V}}{A} = \frac{0.6684 \frac{\text{ft}^3}{\text{sec}}}{0.0884 \text{ ft}^2} = 7.56 \text{ ft/sec}$$

The Reynolds number is

$$\text{Re} = \frac{D\text{v}}{\nu} = \frac{(0.3355 \text{ ft}) \left(7.56 \frac{\text{ft}}{\text{sec}} \right)}{1.41 \times 10^{-5} \frac{\text{ft}^2}{\text{sec}}}$$

$$= 1.8 \times 10^5$$

The relative roughness is

$$\frac{\epsilon}{D} = \frac{0.0002}{0.3355} = 0.0006$$

From the friction factor table (or the Moody friction factor chart), $f = 0.0195$.

Equation 17.23(b) is used to calculate the friction loss.

$$E_f = h_f \times \left(\frac{g}{g_c} \right) = \frac{fLv^2}{2Dg_c}$$

$$= \frac{(0.0195)(1000 \text{ ft}) \left(7.56 \frac{\text{ft}}{\text{sec}} \right)^2}{(2)(0.3355 \text{ ft}) \left(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2} \right)}$$

$$= 51.6 \text{ ft-lbf/lbm}$$

Example 17.4

Calculate the head loss due to friction for the pipe in Ex. 17.3 using the Hazen-Williams formula. Assume $C = 100$.

Solution

Substituting the parameters derived in Ex. 17.3 into Eq. 17.30,

$$h_f = \frac{(3.022) \left(7.56 \frac{\text{ft}}{\text{sec}} \right)^{1.85} (1000 \text{ ft})}{(100)^{1.85} (0.3355 \text{ ft})^{1.165}} = 90.8 \text{ ft}$$

Alternatively, the given data can be substituted directly into Eq. 17.31.

$$h_f = \frac{(10.44)(1000 \text{ ft})(300 \text{ gpm})^{1.85}}{(100)^{1.85} (4.026 \text{ in})^{4.8655}} = 90.9 \text{ ft}$$

10. FRICTION LOSS FOR WATER FLOW IN STEEL PIPES

Friction loss and velocity for water flowing through steel pipe (as well as for other liquids and other pipe materials) in table and chart form are widely available. (Appendix 17.C is an example of such a table.) These tables and charts are unable to compensate for the effects of fluid temperature and different pipe roughness. Unfortunately, the assumptions made in developing the tables and charts are seldom listed. Another disadvantage is that the values can be read to only a few significant figures.

Since water's specific volume is essentially constant within the normal temperature range, tables and charts can be used to determine water velocity. Friction loss data, however, should be considered accurate to only ±20%. Alternatively, a 20% safety margin should be established in choosing pumps and motors.

Tables and charts almost always give the friction loss per 100 ft or 10 m of pipe. The pressure drop is proportional to the length, so the value read can be scaled for other pipe lengths. Flow velocity is independent of pipe length.

11. FRICTION LOSS IN NONCIRCULAR DUCTS

The frictional energy loss by a fluid flowing in a rectangular, annular, or other noncircular duct can be calculated from the Darcy equation by using the *equivalent diameter (hydraulic diameter)*, D_e, in place of the diameter variable, D.[10] The friction factor, f, is determined in any of the conventional manners.

12. FRICTION LOSS FOR STEAM AND GASES

The Darcy equation can be used to calculate the frictional energy loss for all incompressible liquids, not just for water. Alcohol, gasoline, fuel oil, and refrigerants, for example, are all handled well, since the effect of viscosity is considered in determining the friction factor, f.[11]

In fact, the Darcy equation is commonly used with noncondensing vapors and compressed gases, such as air, nitrogen, and steam.[12] In such cases, reasonable accuracy will be achieved as long as the fluid is not moving too fast (i.e., less than Mach 0.3) and is incompressible. The fluid is assumed to be incompressible if the pressure (or density) change along the section of interest is less than 10% of the starting pressure.

If possible, it is preferred to base all calculations on the average properties of the fluid.[13] Specifically, the fluid velocity would normally be calculated as

$$\mathrm{v} = \frac{\dot{m}}{\rho_{\text{ave}} A} \qquad 17.32$$

However, the average density of a gas depends on the average pressure, which is unknown at the start of a problem. The solution is to write the Reynolds number and Darcy equation in terms of the constant mass flow rate per unit area, G, instead of velocity, v, which varies.

$$G = \mathrm{v}_{\text{ave}} \rho_{\text{ave}} \qquad 17.33$$

$$\mathrm{Re} = \frac{DG}{\mu} \qquad \text{[SI]} \qquad 17.34(a)$$

$$\mathrm{Re} = \frac{DG}{g_c \mu} \qquad \text{[U.S.]} \qquad 17.34(b)$$

$$\Delta p_f = p_1 - p_2 = \rho_{\text{ave}} h_f = \frac{fLG^2}{2D\rho_{\text{ave}}} \qquad 17.35$$

[10] Although it is used for both, this approach is better suited for turbulent flow than for laminar flow. Also, the accuracy of this method decreases as the flow area becomes more noncircular. The friction drop in long, narrow slits is poorly predicted, for example. However, there is no other convenient method of predicting friction drop. Experimentation should be used with a particular flow geometry if extreme accuracy is required.

[11] Since viscosity is not an explicit factor in the formula, it should be obvious that the Hazen-Williams equation is primarily used for water.

[12] Use of the Darcy equation is limited only by the availability of the viscosity data needed to calculate the Reynolds number.

[13] Of course, the entrance (or exit) conditions can be used if great accuracy is not needed.

Assuming a perfect gas with a molecular weight of MW, the ideal gas law can be used to calculate ρ_{ave} from the absolute temperature, T, and $p_{\text{ave}} = (p_1 + p_2)/2$.

$$p_1^2 - p_2^2 = \frac{fLG^2 R^* T}{D(\mathrm{MW})} \qquad \text{[SI]} \qquad 17.36(a)$$

$$p_1^2 - p_2^2 = \frac{fLG^2 R^* T}{Dg_c(\mathrm{MW})} \qquad \text{[U.S.]} \qquad 17.36(b)$$

To summarize, use the following guidelines when working with compressible gases or vapors flowing in a pipe or duct. (a) If the pressure drop, based on the entrance pressure, is less than 10%, the fluid can be assumed to be incompressible, and the gas properties can be evaluated at any point known along the pipe. (b) If the pressure drop is between 10% and 40%, use of the midpoint properties will yield reasonably accurate friction losses. (c) If the pressure drop is greater than 40%, the pipe can be divided into shorter sections and the losses calculated for each section, or exact calculations based on compressible flow theory must be made.

Calculating a friction loss for steam flow can be frustrating if steam viscosity data are unavailable. Generally, the steam viscosities listed in compilations of heat transfer data are sufficiently accurate. Various empirical methods are also in use. For example, the *Babcock formula* (Eq. 17.37) for pressure drop when steam with a specific volume of v flows in a pipe of diameter d is

$$\Delta p_{\text{psi}} = (0.470)\left(\frac{d_{\text{in}} + 3.6}{d_{\text{in}}^6}\right)(\dot{m}_{\text{lbm/sec}})^2 L_{\text{ft}} v \qquad 17.37$$

Use of empirical formulas is not limited to steam. Theoretical formulas (e.g., the *complete isothermal flow equation*) and specialized empirical formulas (e.g., the *Weymouth*, *Panhandle*, and *Spitzglass formulas*) have been developed, particularly by the gas pipeline industry. Each of these provides reasonable accuracy within their operating limits. However, none should be used without knowing the assumptions and operational limitations that were used in their derivations.

Example 17.5

0.0011 kg/s of 25°C nitrogen gas flows isothermally through a 175 m section of smooth tubing (inside diameter = 0.012 m). The viscosity of the nitrogen is 1.8×10^{-5} Pa·s. The pressure of the nitrogen is 200 kPa originally. At what pressure is the nitrogen delivered?

SI Solution

The flow area of the pipe is

$$A = \frac{\pi}{4} D^2 = \frac{\pi(0.012\ \text{m})^2}{4} = 1.131 \times 10^{-4}\ \text{m}^2$$

The mass flow rate per unit area is

$$G = \frac{\dot{m}}{A} = \frac{0.0011 \ \frac{\text{kg}}{\text{s}}}{1.131 \times 10^{-4} \ \text{m}^2} = 9.73 \ \text{kg/m}^2\text{·s}$$

The Reynolds number is

$$\text{Re} = \frac{DG}{\mu} = \frac{(0.012 \ \text{m})\left(9.73 \ \frac{\text{kg}}{\text{m}^2\text{·s}}\right)}{1.8 \times 10^{-5} \ \text{Pa·s}} = 6487$$

The flow is turbulent, and the pipe is said to be smooth. Therefore, the friction factor is interpolated (from App. 17.B) as 0.0347.

The molecular weight of nitrogen is 28.0 kg/kmol. The temperature must be in degrees absolute: $T = 25°\text{C} + 273 = 298\text{K}$. The universal gas constant is 8314.3 J/kmol·K.

From Eq. 17.36, the final pressure is

$$p_2^2 = p_1^2 - \frac{fLG^2R^*T}{D(\text{MW})}$$

$$= (200{,}000 \ \text{Pa})^2 - (0.0347)(175 \ \text{m})\left(9.73 \ \frac{\text{kg}}{\text{m}^2\text{·s}}\right)^2 \times \frac{\left(8314.3 \ \frac{\text{J}}{\text{kmol·K}}\right)(298\text{K})}{(0.012 \ \text{m})\left(28 \frac{\text{kg}}{\text{kmol}}\right)}$$

$$= 4 \times 10^{10} \ \text{Pa}^2 - 4.24 \times 10^9 \ \text{Pa}^2 = 3.576 \times 10^{10} \ \text{Pa}^2$$

$$p_2 = \sqrt{3.576 \times 10^{10} \ \text{Pa}^2} = 1.89 \times 10^5 \ \text{Pa} \ \ (189 \ \text{kPa})$$

The percentage drop in pressure should not be more than 10%.

$$\frac{200 \ \text{kPa} - 189 \ \text{kPa}}{200 \ \text{kPa}} = 0.055 \ (5.5\%) \quad \text{[OK]}$$

Example 17.6

Superheated steam at 140 psi and 500°F enters a 200 ft long steel pipe with an internal diameter of 3.826 in. The pipe is insulated so that there is no heat loss. (a) Use the Babcock formula to determine the maximum velocity such that the steam does not experience more than a 10% drop in pressure. (b) Verify the velocity by calculating the pressure drop with the Darcy equation.

Solution

(a) From superheated steam tables, the specific volume of the steam is 3.954 ft^3/lbm. The maximum pressure drop is 10% of 140 psi or 14 psi.

From Eq. 17.37,

$$\Delta p_{\text{psi}} = (0.470)\left(\frac{d_{\text{in}} + 3.6}{d_{\text{in}}^6}\right)(\dot{m}_{\text{lbm/sec}})^2 L_{\text{ft}} v$$

$$14 \ \text{psi} = (0.470)\left[\frac{3.826 \ \text{in} + 3.6}{(3.826 \ \text{in})^6}\right]\dot{m}^2 \times (200 \ \text{ft})\left(3.954 \ \frac{\text{ft}^3}{\text{lbm}}\right)$$

$$\dot{m} = 3.99 \ \text{lbm/sec} \ (4 \ \text{lbm/sec})$$

(b) Assume a Darcy friction factor of 0.02 (typical for turbulent flow in steel pipe). The steam flow velocity is

$$\text{v} = \frac{Q}{A} = \frac{\dot{m}}{\rho A} = \frac{\dot{m}v}{A}$$

$$= \frac{\left(4 \ \frac{\text{lbm}}{\text{sec}}\right)\left(3.954 \ \frac{\text{ft}^3}{\text{lbm}}\right)}{\left(\frac{\pi}{4}\right)\left(\frac{3.826 \ \text{in}}{12 \ \frac{\text{in}}{\text{ft}}}\right)^2}$$

$$= 198 \ \text{ft/sec}$$

$$h_f = \frac{f\text{Lv}^2}{2Dg}$$

$$= \frac{(0.02)(200 \ \text{ft})\left(198 \ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(\frac{3.826 \ \text{in}}{12 \ \frac{\text{in}}{\text{ft}}}\right)\left(32.2 \ \frac{\text{ft}}{\text{sec}^2}\right)}$$

$$= 7637 \ \text{ft of steam}$$

$$\Delta p = \rho h_f \times \left(\frac{g}{g_c}\right) = \left(\frac{h_f}{v}\right) \times \left(\frac{g}{g_c}\right)$$

$$= \left[\frac{7637 \ \text{ft}}{\left(3.954 \ \frac{\text{ft}^3}{\text{lbm}}\right)\left(144 \ \frac{\text{in}^2}{\text{ft}^2}\right)}\right] \times \left(\frac{32.2 \ \frac{\text{ft}}{\text{sec}^2}}{32.2 \ \frac{\text{ft-lbm}}{\text{lbf-sec}^2}}\right)$$

$$= 13.4 \ \text{lbf/in}^2 \ \text{(psi)}$$

13. EFFECT OF VISCOSITY ON HEAD LOSS

Friction loss in a pipe is affected by the fluid viscosity. For both laminar and turbulent flow, viscosity is considered when the Reynolds number is calculated. When

viscosities substantially increase without a corresponding decrease in flow rate, two things usually happen: (a) the friction loss greatly increases, and (b) the flow becomes laminar.

It is sometimes necessary to estimate head loss for a new fluid viscosity based on head loss at an old fluid viscosity. The estimation procedure used depends on the flow regimes for the new and old fluids.

For laminar flow, the friction factor is directly proportional to the viscosity. If the flow is laminar for both fluids, the ratio of new-to-old head losses will be equal to the ratio of new-to-old viscosities. Thus, if a flow is already known to be laminar at one viscosity and the fluid viscosity increases, a simple ratio will define the new friction loss.

If both flows are fully turbulent, the friction factor will not change. If flow is fully turbulent and the viscosity decreases, the Reynolds number will increase. Theoretically, this will have no effect on the friction loss.

There are no analytical ways of estimating the change in friction loss when the flow regime changes between laminar and turbulent or between semiturbulent and fully turbulent. Various graphical methods are used, particularly by the pump industry, for calculating power requirements.

14. FRICTION LOSS WITH SLURRIES AND NON-NEWTONIAN FLUIDS

A *slurry* is a mixture of a liquid (usually water) and a solid (e.g., coal, paper pulp, foodstuffs). The liquid is generally used as the transport mechanism (i.e., the *carrier*) for the solid.

Friction loss calculations for slurries vary in sophistication depending on what information is available. In many cases, only the slurry's specific gravity is known. In that case, use is made of the fact that friction loss can be reasonably predicted by multiplying the friction loss based on the pure carrier (e.g., water) by the specific gravity of the slurry.

Another approach is possible if the density and viscosity in the operating range are known. The traditional Darcy equation (Eq. 17.28) and Reynolds number can be used for thin slurries as long as the flow velocity is high enough to keep solids from settling. (Settling is more of a concern for laminar flow. With turbulent flow, the direction of velocity components fluctuates, assisting the solids to remain in suspension.)

The most analytical approach to slurries or other non-Newtonian fluids requires laboratory-derived rheological data. Non-Newtonian viscosity (η, in Pa·s) is fitted to data of the shear rate (dv/dy, in s^{-1}) according to two common models: the power-law model and the Bingham-plastic model. (These two models are applicable to both laminar and turbulent flow, although each has its advantages and disadvantages.)

The *power-law model* has two empirical constants, m and n, that must be determined.

$$\eta = m\left(\frac{dv}{dy}\right)^{n-1} \qquad 17.38$$

The *Bingham-plastic model* also requires finding two empirical constants: the yield stress τ_0 (in Pa) and the Bingham-plastic limiting viscosity μ_∞ (in Pa·s).

$$\eta = \frac{\tau_0}{\frac{dv}{dy} + \mu_\infty} \qquad 17.39$$

Once m and n (or τ_0 and μ_∞) have been determined, the friction factor is determined from one of various models (e.g., Buckingham-Reiner, Dodge-Metzner, Metzner-Reed, Hanks-Ricks, Darby, or Hanks-Dadia). Specialized texts and articles cover these models in greater detail. The friction loss is calculated from the traditional Moody equation.

15. MINOR LOSSES

In addition to the frictional energy lost due to viscous effects, friction losses also result from fittings in the line, changes in direction, and changes in flow area. These losses are known as *minor losses*, since they are usually much smaller in magnitude than the pipe wall frictional loss.[14] Two methods are used to calculate minor losses: equivalent lengths and loss coefficients.

With the *method of equivalent lengths*, each fitting or other flow variation is assumed to produce friction equal to the pipe wall friction from an *equivalent length* of pipe. For example, a 2 in globe valve may produce the same amount of friction as 54 ft (its equivalent length) of 2 in pipe. The equivalent lengths for all minor losses are added to the pipe length term, L, in the Darcy equation. This method can be used with all liquids, but it is generally limited to turbulent flow.

$$L_t = L + \sum L_e \qquad 17.40$$

Equivalent lengths are simple to use, but the method depends on having a table of equivalent length values. The actual value for a fitting will depend on the fitting manufacturer, as well as the fitting material (e.g., brass, cast iron, or steel) and the method of attachment (e.g.,

[14]Example and practice problems often include the instruction to "Ignore minor losses." In some industries, valves are considered to be "components," not fittings. In such cases, instructions to "Ignore minor losses in fittings" would be ambiguous, since minor losses in valves would be included in the calculations. However, this interpretation is rare in examples and practice problems.

weld, thread, or flange).[15] Because of these many variations, it may be necessary to use a "generic table" of equivalent lengths during the initial design stages. (See Table 17.3 and App. 17.D.)

Table 17.3 *Typical Equivalent Lengths (schedule-40, screwed steel fittings)*

fitting type	pipe size 1″	2″	4″
	equivalent length, ft		
angle valve	17.0	18.0	18.0
coupling or union	0.29	0.45	0.65
gate valve	0.84	1.5	2.5
globe valve	29.0	54.0	110.0
long radius 90° elbow	2.7	3.6	4.6
regular 45° elbow	1.3	2.7	5.5
regular 90° elbow	5.2	8.5	13.0
swing check valve	11.0	19.0	38.0
tee, flow through line (run)	3.2	7.7	17.0
tee, flow through stem	6.6	12.0	21.0
180° return bend	5.2	8.5	13.0

An alternative method of calculating the minor loss for a fitting is to use the *method of loss coefficients.* Each fitting has a *loss coefficient*, K, associated with it, which, when multiplied by the kinetic energy, gives the loss. Thus, a loss coefficient is the minor loss expressed in fractions (or multiples) of the velocity head.

$$h_m = Kh_v \qquad 17.41$$

The loss coefficient for any minor loss can be calculated if the equivalent length is known. However, there is no advantage to using one method over the other, except for consistency in calculations.

$$K = \frac{fL_e}{D} \qquad 17.42$$

Exact friction loss coefficients for bends, fittings, and valves are unique to each manufacturer. Furthermore, except for contractions, enlargements, exits, and entrances, the coefficients decrease fairly significantly (according to the fourth power of the diameter ratio) with increases in valve size. Therefore, a single K value is seldom applicable to an entire family of valves. Nevertheless, generic tables and charts have been developed. These compilations can be used for initial estimates as long as the general nature of the data is recognized.

[15] In the language of pipe fittings, a *threaded fitting* is known as a *screwed fitting*, even though no screws are used.

Table 17.4 *Typical Loss Coefficients*[a]

device	K
angle valve	5
bend, close return	2.2
butterfly valve[b]	
2 to 8 in	$45f_t$
10 to 14 in	$35f_t$
16 to 24 in	$25f_t$
check valve, swing, fully open	2.3
corrugated bends	1.3 to 1.6 times value for smooth bend
standard 90° elbow	0.9
long radius 90° elbow	0.6
45° elbow	0.42
gate valve	
fully open	0.19
1/4 closed	1.15
1/2 closed	5.6
3/4 closed	24
globe valve	10
meter	
disk or wobble	3.4 to 10
rotary (star or cog-wheel piston)	10
reciprocating piston	15
turbine wheel (double flow)	5 to 7.5
tee, standard	1.8

[a] The actual loss coefficient will usually depend on the size of the valve. Average values are given.
[b] Loss coefficients for butterfly valves are calculated from the friction factors for the pipes with complete turbulent flow.

Loss coefficients for specific fittings and valves must be known in order to be used. They cannot be derived theoretically. However, the loss coefficients for certain changes in flow area can be calculated from the following equations.[16]

- *sudden enlargements:* (D_1 is the smaller of the two diameters)

$$K = \left[1 - \left(\frac{D_1}{D_2}\right)^2\right]^2 \qquad 17.43$$

- *sudden contractions:* (D_1 is the smaller of the two diameters)

$$K = \tfrac{1}{2}\left[1 - \left(\frac{D_1}{D_2}\right)^2\right] \qquad 17.44$$

- *pipe exit:* (projecting exit, sharp-edged or rounded)

$$K = 1.0 \qquad 17.45$$

[16] No attempt is made to imply great accuracy with these equations. Correlation between actual and theoretical losses is fair.

- *pipe entrance:*

  reentrant: $K = 0.78$

  sharp-edged: $K = 0.50$

  rounded:

$\frac{\text{bend radius}}{D}$	K
0.02	0.28
0.04	0.24
0.06	0.15
0.10	0.09
0.15	0.04

- *tapered diameter changes:*

$$\beta = \frac{\text{small diameter}}{\text{large diameter}} = \frac{D_1}{D_2}$$

ϕ = wall-to-horizontal angle

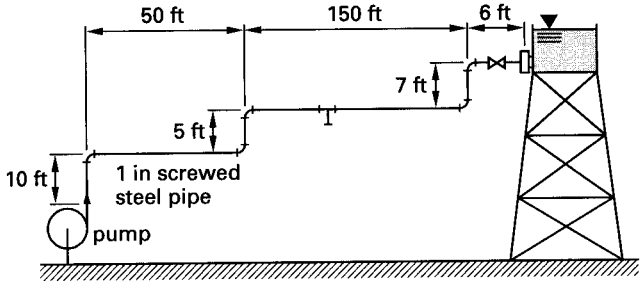
enlargement, $\phi \leq 22°$:

$$K = 2.6 \sin\phi \, (1 - \beta^2)^2 \qquad 17.46$$

enlargement, $\phi > 22°$:

$$K = (1 - \beta^2)^2 \qquad 17.47$$

contraction, $\phi \leq 22°$:



$$K = 0.8 \sin\phi \, (1 - \beta^2) \qquad 17.48$$

contraction, $\phi > 22°$:

$$K = 0.5 \sqrt{\sin\phi} \, (1 - \beta^2) \qquad 17.49$$

Example 17.7

Determine the total equivalent length of the piping system shown. The pipeline contains one gate valve, five regular 90° elbows, one tee (flow through the run), and 228 ft of straight pipe. All fittings are 1 in screwed steel pipe. Disregard entrance and exit losses.

Solution

From Table 17 3, the individual and total equivalent lengths are

1	gate valve	1×0.84	=	0.84
5	regular elbows	5×5.2	=	26.0
1	tee run	1×3.2	=	3.2
	straight pipe			228.0
			total L_t =	258.0 ft

16. VALVE FLOW COEFFICIENTS

Valve flow capacities depend on the geometry of the inside of the valve. The *flow coefficient*, C_v, for a valve (particularly a control valve) relates the flow quantity (in gallons per minute) of a fluid with specific gravity to the pressure drop (in pounds per square inch). (The flow coefficient for a valve is not the same as the coefficient of flow for an orifice or venturi meter.) As Eq. 17.50 shows, the flow coefficient is not dimensionally homogeneous and is specifically limited to English units.

$$Q_{gpm} = C_v \sqrt{\frac{\Delta p_{psi}}{SG}} \qquad 17.50$$

When selecting a control valve for a particular application, the value of C_v is first calculated. Depending on the application and installation, C_v may be further modified by dividing by *piping geometry* and *Reynolds number factors*. (These additional procedures are often specified by the valve manufacturer.) Then, a valve with the required value of C_v is selected.

Although the flow coefficient concept is generally limited to control valves, its use can be extended to all fittings and valves. The relationship between C_v and the loss coefficient, K, is

$$C_v = \frac{29.9 d_{in}^2}{\sqrt{K}} \qquad 17.51$$

17. SHEAR STRESS IN CIRCULAR PIPES

Shear stress in fluid always acts to oppose the motion of the fluid. (That is the reason the term *frictional force* is occasionally used.) Shear stress for a fluid in laminar flow can always be calculated from the basic definition of absolute viscosity.

$$\tau = \mu \frac{dv}{dy} \qquad 17.52$$

In the case of the flow in a circular pipe, dr can be substituted for dy in the expression for *shear rate (velocity gradient)*, dv/dy.

$$\tau = \mu \frac{dv}{dr} \qquad 17.53$$

Equation 17.54 calculates the shear stress between fluid layers a distance r from the pipe centerline from the pressure drop across a length L of the pipe.[17] Equation 17.54 is valid for both laminar and turbulent flows.

$$\tau = \frac{(p_1 - p_2)r}{2L} \quad \left[r \leq \tfrac{D}{2}\right] \qquad 17.54$$

[17] In highly turbulent flow, shear stress is not caused by viscous effects but rather by momentum effects. Equation 17.54 is derived from a shell momentum balance. Such an analysis requires the concept of *momentum flux*. In a circular pipe with laminar flow, momentum flux is maximum at the pipe wall, zero at the flow centerline, and varies linearly in between.

The quantity $(p_1 - p_2)$ can be calculated from the Darcy equation (Eq. 17.28). If v is the average flow velocity, the shear stress at the wall (where $r = D/2$) is

$$\tau_{\text{wall}} = \frac{f\rho v^2}{8} \quad \text{[SI]} \quad 17.55(a)$$

$$\tau_{\text{wall}} = \frac{f\rho v^2}{8g_c} \quad \text{[U.S.]} \quad 17.55(b)$$

Equation 17.54 can be rearranged somewhat to give the relationship between the pressure gradient and the shear stress at the wall.

$$\frac{dp}{dL} = \frac{4\tau_{\text{wall}}}{D} \quad 17.56$$

Equation 17.55 can be combined with the Hagen-Poiseuille equation (Eq. 17.24) if the flow is laminar. (v in Eq. 17.57 is the average velocity of fluid flow.)

$$\tau = \frac{16\mu v r}{D^2} \quad \left[r \le \tfrac{D}{2}\right] \quad 17.57$$

At the pipe wall, $r = D/2$ and the shear stress is maximum. Therefore,

$$\tau_{\text{wall}} = \frac{8\mu v}{D} \quad 17.58$$

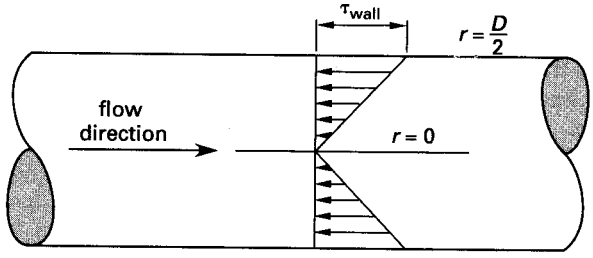


Figure 17.5 *Shear Stress Distribution in a Circular Pipe*

18. INTRODUCTION TO PUMPS AND TURBINES[18]

A *pump* adds energy to the fluid flowing through it. The amount of energy that a pump puts into the fluid stream can be determined by the difference between the total energy on either side of the pump. In most situations, a pump will add primarily pressure energy. The specific energy added (a positive number) on a per-unit mass basis (i.e., ft-lbf/lbm or J/kg) is given by Eq. 17.59.

$$E_A = E_{t,2} - E_{t,1} \quad 17.59$$

[18]Pumps and turbines are covered in greater detail in Chap. 18.

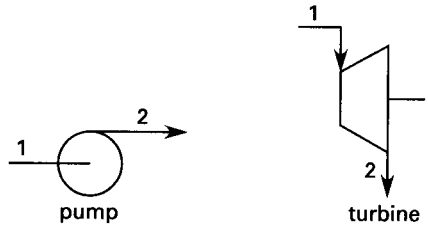

Figure 17.6 *Pump and Turbine Representation*

The *head added* by a pump is

$$h_A = \frac{E_A}{g} \quad \text{[SI]} \quad 17.60(a)$$

$$h_A = \frac{E_A g_c}{g} \quad \text{[U.S.]} \quad 17.60(b)$$

The specific energy added by a pump can also be calculated from the input power if the mass flow rate is known. The input power to the pump will be the output power of the electric motor or engine driving the pump.

$$E_A = \frac{\left(1000 \frac{\text{W}}{\text{kW}}\right)(P_{\text{kW,input}})(\eta_{\text{pump}})}{\dot{m}} \quad \text{[SI]} \quad 17.61(a)$$

$$E_A = \frac{\left(550 \frac{\text{ft-lbf}}{\text{sec-hp}}\right)(P_{\text{hp,input}})(\eta_{\text{pump}})}{\dot{m}} \quad \text{[U.S.]} \quad 17.61(b)$$

The *water horsepower* (WHP, also known as the *hydraulic horsepower* and *theoretical horsepower*) is the amount of power actually entering the fluid.

$$\text{WHP} = (P_{\text{hp,input}})\,\eta_{\text{pump}} \quad 17.62$$

A *turbine* extracts energy from the fluid flowing through it. As with a pump, the energy extraction can be obtained by evaluating the Bernoulli equation on both sides of the turbine and taking the difference. The energy extracted (a positive number) on a per-unit mass basis is given by Eq. 17.63.

$$E_E = E_{t,1} - E_{t,2} \quad 17.63$$

19. EXTENDED BERNOULLI EQUATION

The original Bernoulli equation assumes frictionless flow and does not consider the effects of pumps and turbines. When friction is present and when there are minor losses such as fittings and other energy-related devices in a pipeline, the energy balance is affected. The *extended Bernoulli equation* takes these additional factors into account.

$$(E_p + E_v + E_z)_1 + E_A = (E_p + E_v + E_z)_2 + E_E + E_f + E_m \quad 17.64$$

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} + z_1 g + E_A = \frac{p_2}{\rho} + \frac{v_2^2}{2} + z_2 g + E_E + E_f + E_m \quad \text{[SI]} \quad 17.65(a)$$

$$\frac{p_1}{\rho} + \frac{v_1^2}{2g_c} + \frac{z_1 g}{g_c} + E_A = \frac{p_2}{\rho} + \frac{v_2^2}{2g_c} + \frac{z_2 g}{g_c} + E_E + E_f + E_m \quad \text{[U.S.]} \quad 17.65(b)$$

As defined, E_A, E_E, and E_f are all positive terms. None of the terms in Eq. 17.64 is negative.

The concepts of sources and sinks can be used to decide whether the friction, pump, and turbine terms appear on the left or right side of the Bernoulli equation. An *energy source* puts energy into the system. The incoming fluid and a pump contribute energy to the system. An *energy sink* removes energy from the system. The leaving fluid, friction, and a turbine remove energy from the system. In an energy balance, all energy must be accounted for, and the energy sources just equal the energy sinks.

$$\sum E_{\text{sources}} = \sum E_{\text{sinks}} \quad 17.66$$

Therefore, the energy added by a pump always appears on the entrance side of the Bernoulli equation. Similarly, the frictional energy loss always appears on the discharge side.

20. ENERGY AND HYDRAULIC GRADE LINES WITH FRICTION[19]

The *energy grade line* (EGL, also known as *total energy line*) is a graph of the total energy versus position in a pipeline. Since a pitot tube measures total (stagnation) energy, EGL will always coincide with the elevation of a pitot-piezometer fluid column. When friction is present, the EGL will always slope down, in the direction of flow. Figure 17.7 illustrates the EGL for a complex pipe network. The difference between $\text{EGL}_{\text{frictionless}}$ and $\text{EGL}_{\text{with friction}}$ is the energy loss due to friction.

Notice that the EGL line in Figure 17.7 is discontinuous at point 2, since the friction in pipe section B-C cannot be portrayed without disturbing the spatial correlation of points in the figure. Since the friction loss is proportional to v^2, the slope is steeper when the fluid velocity increases (i.e., when the pipe decreases in flow area), as it does in section D-E. Disregarding air friction, the EGL becomes horizontal at point 6 when the fluid becomes a free jet.

The *hydraulic grade line* (HGL) is a graph of the sum of pressure and potential energies versus position in the pipeline. (That is, the EGL and HGL differ by the kinetic energy.) The HGL will always coincide with

[19]The energy grade line and hydraulic grade line were covered in Ch. 16 for the frictionless case.

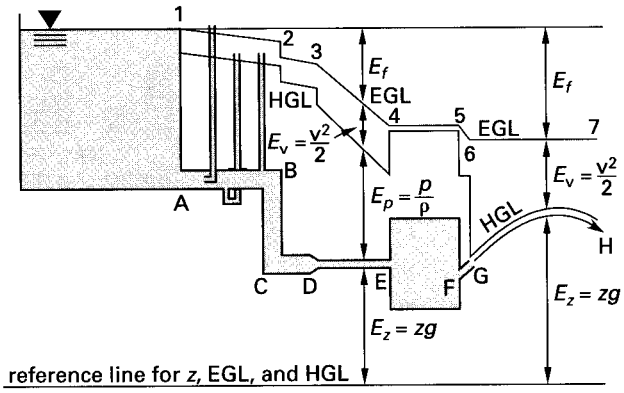

Figure 17.7 *Energy and Hydraulic Grade Lines*

the height of the fluid column in a static piezometer tube. The reference point for elevation is arbitrary, and the pressure energy is usually referenced to atmospheric pressure. Thus, the pressure energy, E_p, for a free jet will be zero, and the HGL will consist only of the potential energy, as shown in section G-H.

The easiest way to draw the energy and hydraulic grade lines is to start with the EGL. The EGL can be drawn simply by recognizing that the rate of divergence from the horizontal $\text{EGL}_{\text{frictionless}}$ line is proportional to v^2. Then, since EGL and HGL differ by the velocity head, the HGL can be drawn parallel to the EGL when the pipe diameter is constant. The larger the pipe diameter, the closer the two lines will be.

The EGL for a pump will increase in elevation by E_A across the pump. (The actual energy "path" taken by the fluid is unknown, and a dotted line is used to indicate a lack of knowledge about what really happens in the pump.) The placement of the HGL for a pump will depend on whether the pump increases the fluid velocity and elevation as well as the fluid pressure. In most cases, only the pressure will be increased. Figure 17.8 illustrates the HGL for the case of a pressure increase only.

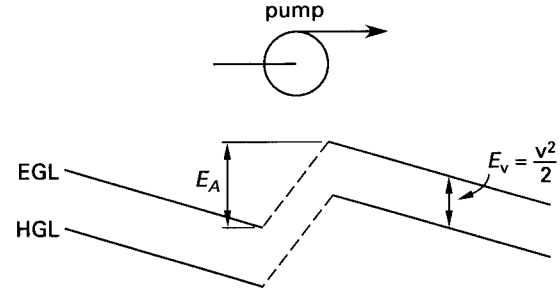

Figure 17.8 *EGL and HGL for a Pump*

The EGL and HGL for minor losses (fittings, contractions, expansions, etc.) are shown in Fig. 17.9.

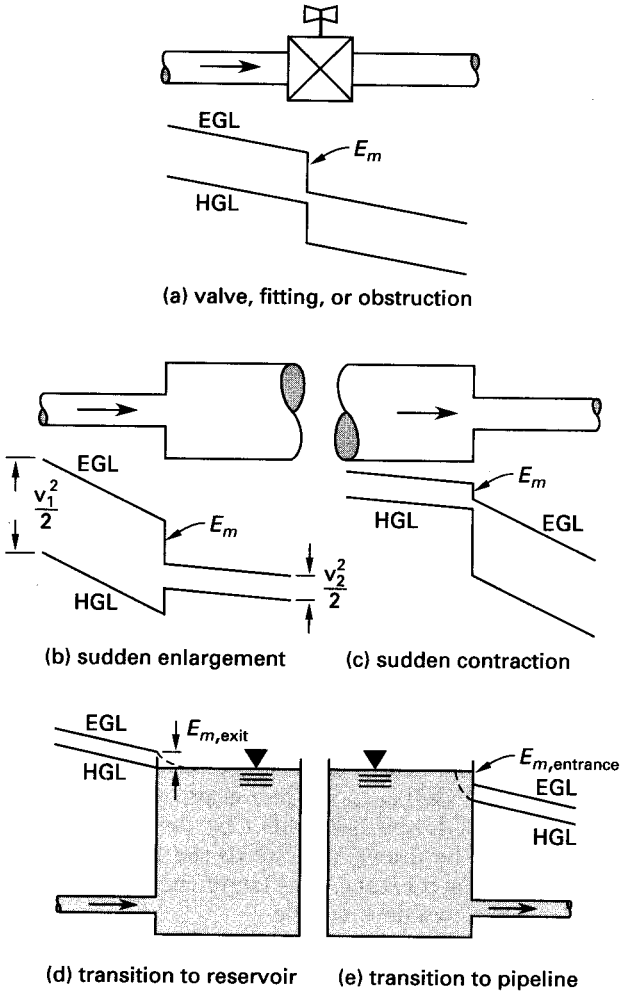

Figure 17.9 *EGL and HGL for Minor Losses*

21. DISCHARGE FROM TANKS

The velocity of a jet issuing from an orifice in a tank can be determined by comparing the total energies at the free fluid surface and the jet itself. At the fluid surface, $p_1 = 0$ (atmospheric) and $v_1 = 0$. (v_1 is known as the *velocity of approach.*) The only energy the fluid has is potential energy. At the jet, $p_2 = 0$. All of the potential energy difference $(z_1 - z_2)$ has been converted to kinetic energy. The theoretical velocity of the jet can be derived from the Bernoulli equation. Equation 17.67 is known as the equation for *Torricelli's speed of efflux.*

$$v_t = \sqrt{2gh} \qquad 17.67$$

$$h = z_1 - z_2 \qquad 17.68$$

The actual jet velocity is affected by the orifice geometry. The *coefficient of velocity*, C_v, is an empirical factor that accounts for the friction and turbulence at the orifice. Typical values of C_v are given in Table 17.5.

$$v_o = C_v\sqrt{2gh} \qquad 17.69$$

$$C_v = \frac{\text{actual velocity}}{\text{theoretical velocity}} = \frac{v_o}{v_t} \qquad 17.70$$

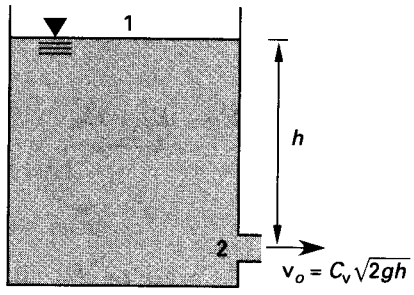

Figure 17.10 *Discharge from a Tank*

The specific energy loss due to turbulence and friction at the orifice is calculated as a multiple of the jet's kinetic energy.

$$E_f = \left(\frac{1}{C_v^2} - 1\right)\left(\frac{v_o^2}{2}\right) = \left(1 - C_v^2\right) gh \quad \text{[SI]} \qquad 17.71(a)$$

$$E_f = \left(\frac{1}{C_v^2} - 1\right)\left(\frac{v_o^2}{2g_c}\right) = \left(1 - C_v^2\right) h \times \left(\frac{g}{g_c}\right)$$

[U.S.] 17.71(b)

The total head producing discharge (*effective head*) is the difference in elevations that would produce the same velocity from a frictionless orifice.

$$h_{\text{effective}} = C_v^2 h \qquad 17.72$$

The orifice guides quiescent water from the tank into the jet geometry. Unless the orifice is very smooth and the transition is gradual, momentum effects will continue to cause the jet to contract after it has passed through. The velocity calculated from Eq. 17.69 is usually assumed to be the velocity at the *vena contracta*, the section of smallest cross-sectional area.

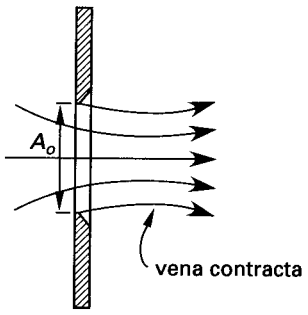

Figure 17.11 *Vena Contracta of a Fluid Jet*

For a thin plate or sharp-edged orifice, the vena contracta is often assumed to be located approximately one half an orifice diameter past the orifice, although the distance can vary from $0.3D_o$ to $0.8D_o$. The area of the vena contracta can be calculated from the orifice area and the *coefficient of contraction*, C_c. For water flowing with a high Reynolds number through a small sharp-edged orifice, the contracted area is approximately 61 to 63% of the orifice area.

Table 17.5 *Approximate Orifice Coefficients for Turbulent Water*

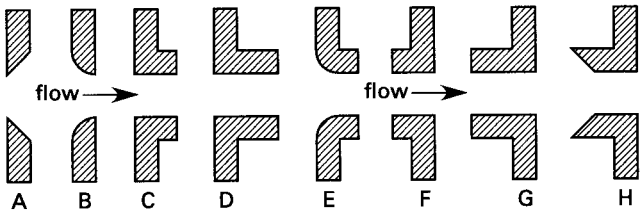

illustration	description	C_d	C_c	C_v
A	sharp-edged	0.62	0.63	0.98
B	round-edged	0.98	1.00	0.98
C	short tube (fluid separates from walls)	0.61	1.00	0.61
D	sharp tube (no separation)	0.82	1.00	0.82
E	sharp tube with rounded entrance	0.97	0.99	0.98
F	reentrant tube, length less than one-half of pipe diameter	0.54	0.55	0.99
G	reentrant tube, length 2 to 3 pipe diameters	0.72	1.00	0.72
H	Borda	0.51	0.52	0.98
(none)	smooth, well-tapered nozzle	0.98	0.99	0.99

$$A_{\text{vena contracta}} = C_c A_o \qquad 17.73$$

$$C_c = \frac{\text{area of vena contracta}}{\text{orifice area}} \qquad 17.74$$

The theoretical discharge rate from a tank is $\dot{V} = A_o\sqrt{2gh}$. However, this relationship needs to be corrected for friction and contraction by multiplying by C_v and C_c. The *coefficient of discharge*, C_d, is the product of the coefficients of velocity and contraction.

$$\dot{V} = C_c v_o A_o = C_d v_t A_o = C_d A_o\sqrt{2gh} \qquad 17.75$$

$$C_d = C_v C_c = \frac{\text{actual discharge}}{\text{theoretical discharge}} \qquad 17.76$$

22. DISCHARGE FROM PRESSURIZED TANKS

If the gas or vapor above the liquid in a tank is at gage pressure p, and the discharge is to atmospheric pressure, the head causing discharge will be

$$h = z_1 - z_2 + \frac{p}{\rho g} \quad \text{[SI]} \qquad 17.77(a)$$

$$h = z_1 - z_2 + \left(\frac{p}{\rho}\right) \times \left(\frac{g_c}{g}\right) \quad \text{[U.S.]} \qquad 17.77(b)$$

The discharge velocity can be calculated from Eq. 17.69 using the increased discharge head.

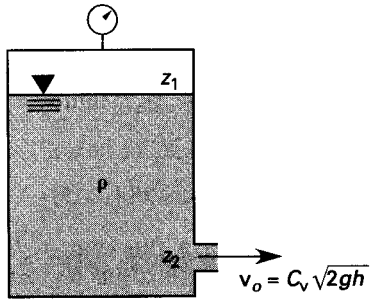

Figure 17.12 *Discharge from a Pressurized Tank*

23. COORDINATES OF A FLUID STREAM

Fluid discharged from an orifice in a tank gets its initial velocity from the conversion of potential energy. After discharge, no additional energy conversion occurs, and all subsequent velocity changes are due to external forces.

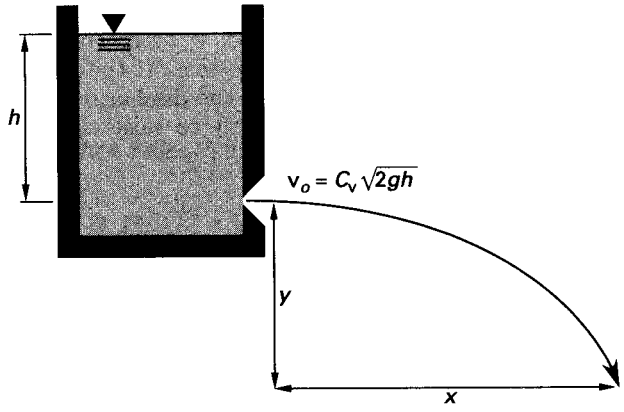

Figure 17.13 *Coordinates of a Fluid Stream*

In the absence of air friction (drag), there are no retarding or accelerating forces in the x-direction on the fluid stream. The x-component of velocity is constant.

$$v_x = v_o \qquad 17.78$$

$$x = v_o t = v_o\sqrt{\frac{2y}{g}} = 2C_v\sqrt{hy} \qquad 17.79$$

After discharge, the fluid stream is acted upon by a constant gravitational acceleration. The y-component of velocity is zero at discharge but increases linearly with time.

$$v_y = gt \qquad 17.80$$

$$y = \frac{gt^2}{2} = \frac{gx^2}{2v_o^2} = \frac{x^2}{4hC_v^2} \qquad 17.81$$

24. TIME TO EMPTY A TANK

If the fluid in an open or vented tank is not replenished at the rate of discharge, the static head forcing discharge through the orifice will decrease with time. If the tank has a varying cross section, A_t, Eq. 17.82 specifies the basic relationship between the change in elevation and elapsed time. (The negative sign indicates that z decreases as t increases.)

$$\dot{V}dt = -A_t dz \qquad 17.82$$

If A_t can be expressed as a function of h, Eq. 17.83 can be used to determine the time to lower the fluid elevation from z_1 to z_2.

$$t = \int_{z_1}^{z_2} \frac{-A_t dz}{C_d A_o\sqrt{2gz}} \qquad 17.83$$

For a tank with a constant cross-sectional area, A_t, the time required to lower the fluid elevation is

$$t = \frac{2A_t(\sqrt{z_1} - \sqrt{z_2})}{C_d A_o\sqrt{2g}} \qquad 17.84$$

If a tank is replenished at a rate of $\dot{V}_{in}$, Eq. 17.85 can be used to calculate the discharge time. If the tank is replenished at a rate greater than the discharge rate, t in Eq. 17.85 will represent the time to raise the fluid level from z_1 to z_2.

$$t = \int_{z_1}^{z_2} \frac{A_t dz}{(C_d A_o\sqrt{2gz}) - \dot{V}_{in}} \qquad 17.85$$

Example 17.8

A tank 15 ft in diameter discharges 150°F water ($\rho = 61.20$ lbm/ft^3) through a sharp-edged 1.0 in diameter orifice ($C_d = 0.62$) in the bottom. The original water depth is 12 ft. The tank is continually pressurized to 50 psig. What is the time to empty the tank?

Solution

The area of the orifice is

$$A_o = \frac{\pi D^2}{4} = \frac{\pi(1\text{ in})^2}{(4)\left(12\ \frac{\text{in}}{\text{ft}}\right)^2} = 0.00545\text{ ft}^2$$

The tank area constant with respect to z is

$$A_t = \frac{\pi D^2}{4} = \frac{\pi(15\text{ ft})^2}{4} = 176.7\text{ ft}^2$$

The total initial head includes the effect of the pressurization.

$$z_1 = 12\text{ ft} + \left[\frac{\left(50\ \frac{\text{lbf}}{\text{in}^2}\right)\left(144\ \frac{\text{in}^2}{\text{ft}^2}\right)}{61.2\ \frac{\text{lbm}}{\text{ft}^3}}\right]\left(\frac{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}{32.2\ \frac{\text{ft}}{\text{sec}^2}}\right)$$

$$= 12\text{ ft} + 117.6\text{ ft} = 129.6\text{ ft}$$

When the fluid has reached the level of the orifice, the fluid potential head will be zero, but the pressurization will remain.

$$z_2 = 117.6\text{ ft}$$

The time to empty the tank is given by Eq. 17.84.

$$t = \frac{(2)(176.7\text{ ft}^2)\left(\sqrt{129.6\text{ ft}} - \sqrt{117.6\text{ ft}}\right)}{(0.62)(0.00545\text{ ft}^2)\sqrt{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}}$$

$$= 7036\text{ sec}$$

25. DISCHARGE FROM LARGE ORIFICES

When an orifice diameter is large compared with the discharge head, the jet velocity at the top edge of the orifice will be less than the velocity at the bottom edge. Since the velocity is related to the square root of the head, the distance used to calculate the effective jet velocity should be measured from the fluid surface to a point above the centerline of the orifice.

This correction is generally neglected, however, since it is small for heads of more than twice the orifice diameter. Furthermore, if an orifice is intended to work regularly with small heads, the orifice should be calibrated in place. The discrepancy can then be absorbed into the discharge coefficient, C_d.

26. CULVERTS

A *culvert* is a water path (usually a large diameter pipe) used to channel water around or through an obstructing feature. In most instances, a culvert is used to restore a natural water path obstructed by a manufactured feature. For example, when a road is built across (perpendicular to) a natural ravine or arroyo, a culvert can be used to channel water under the road.

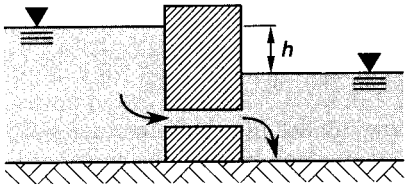

Figure 17.14 *Simple Pipe Culvert*

Because culverts usually operate only partially full and with low heads, Torricelli's equation does not apply. Therefore, most culvert designs are empirical. However, if the entrance and exit of a culvert are both submerged, the culvert will flow full, and the discharge will be independent of the barrel slope. Equation 17.86 can be used to calculate the discharge.

$$\dot{V} = C_d A\sqrt{2gh} \qquad 17.86$$

If the culvert is long (more than 60 ft or 20 m), or if the entrance is not gradual, the available energy will be divided between friction and velocity heads. The effective head used in Eq. 17.86 should be

$$h_{\text{effective}} = h - h_{f,\text{barrel}} - h_{m,\text{entrance}} \qquad 17.87$$

The friction loss in the barrel can be found in the usual manner, from either the Darcy equation or the Hazen-Williams equation. The entrance loss is calculated using the standard method of loss coefficients. Representative values of the loss coefficient, K, are given in Table 17.6. Since the fluid velocity is not initially known but is needed to find the friction factor, a trial-and-error solution will be necessary.

Table 17.6 *Representative Loss Coefficients for Culvert Entrances*

entrance	K
smooth and gradual transition	0.08
flush vee or bell shape	0.10
projecting vee or bell shape	0.15
flush, square-edged	0.50
projecting, square-edged	0.90

27. SIPHONS

A *siphon* is a bent or curved tube that carries fluid from a container at a high elevation to another container at a lower elevation. Normally, it would not seem difficult to have a fluid flow to a lower elevation. However, the fluid seems to flow "uphill" in a siphon. Figure 17.15 illustrates a siphon.

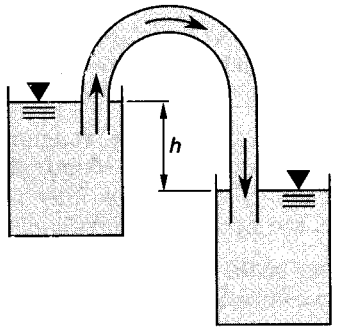

Figure 17.15 *Siphon*

Starting a siphon requires the tube to be completely filled with liquid. Then, since the fluid weight is greater in the longer arm than in the shorter arm, the fluid in the longer arm "falls" out of the siphon, "pulling" more liquid into the shorter arm and over the bend.

Operation of a siphon is essentially independent of atmospheric pressure. The theoretical discharge is the same as predicted by the Torricelli equation. A correction for discharge is necessary, but little data is available on typical values of C_d. Therefore, siphons should be tested and calibrated in place.

$$\dot{V} = C_d A\text{v} = C_d A\sqrt{2gh} \qquad 17.88$$

28. SERIES PIPE SYSTEMS

A system of pipes in series consists of two or more lengths of different-diameter pipes connected together. In the case of the series pipe from a reservoir discharging to the atmosphere shown in Fig. 17.16, the available head will be split between the velocity head and the friction loss.

$$h = h_{\text{v}} + h_f \qquad 17.89$$

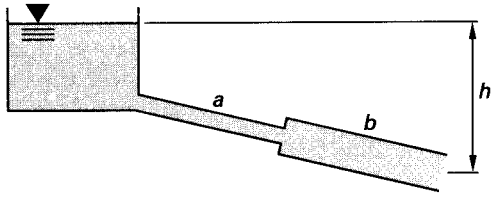

Figure 17.16 *Series Pipe System*

If the flow rate or velocity in any part of the system is known, the friction loss can easily be found as the sum of the friction losses in the individual sections. The solution is somewhat more simple than first appears, since the velocity of all sections can be written in terms of only one velocity.

$$h_{f,t} = h_{f,a} + h_{f,b} \qquad 17.90$$

$$A_a\text{v}_a = A_b\text{v}_b \qquad 17.91$$

If neither the velocity nor the flow quantity is known, a trial-and-error solution will be required, since a friction factor must be known to calculate h_f. A good starting point is to assume fully turbulent flow.

When velocity and flow rate are both unknown, the following procedure using the Darcy friction factor can be used.[20]

step 1: Calculate the relative roughness, ϵ/D, for each section. Use the Moody diagram to determine f_a and f_b for fully turbulent flow (i.e., the horizontal portion of the curve).

step 2: Write all of the velocities in terms of one unknown velocity.

$$\dot{V}_a = \dot{V}_b \qquad 17.92$$

$$\mathrm{v}_b = \left(\frac{A_a}{A_b}\right)\mathrm{v}_a \qquad 17.93$$

step 3: Write the total friction loss in terms of the unknown velocity.

$$\begin{aligned} h_{f,t} &= \frac{f_a L_a \mathrm{v}_a^2}{2D_a g} + \left(\frac{f_b L_b}{2D_b g}\right)\left(\frac{A_a}{A_b}\right)^2 \mathrm{v}_a^2 \\ &= \left(\frac{\mathrm{v}_a^2}{2g}\right)\left(\left(\frac{f_a L_a}{D_a}\right) + \left(\frac{f_b L_b}{D_b}\right)\left(\frac{A_a}{A_b}\right)^2\right) \end{aligned} \qquad 17.94$$

step 4: Solve for the unknown velocity using the Bernoulli equation between the free reservoir surface ($p = 0$, $\mathrm{v} = 0$, $z = h$) and the discharge point ($p = 0$, if free discharge; $z = 0$). Include pipe friction, but disregard minor losses for convenience.

$$\begin{aligned} h &= \frac{\mathrm{v}_b}{2g} + h_{f,t} \\ &= \left(\frac{\mathrm{v}_a^2}{2g}\right)\left(\left(\frac{A_a}{A_b}\right)^2\left(1 + \frac{f_b L_b}{D_b}\right) + \frac{f_a L_a}{D_a}\right) \end{aligned} \qquad 17.95$$

step 5: Using the value of v_a, calculate v_b. Calculate the Reynolds number and check the values of f_a and f_b from step 4. Repeat steps 3 and 4 if necessary.

29. PARALLEL PIPE SYSTEMS

A *pipe loop* is a set of two pipes placed in parallel, both originating and terminating at the same junction. Adding a second pipe in parallel with a first is a standard method of increasing the capacity of a line.

[20]If Hazen-Williams constants are given for the pipe sections, the procedure for finding the unknown velocities is similar, although considerably more difficult since v^2 and $\mathrm{v}^{1.85}$ cannot be combined. A first approximation, however, can be obtained by replacing $\mathrm{v}^{1.85}$ in the Hazen-Williams equation for friction loss. A trial and error method can then be used to find velocity.

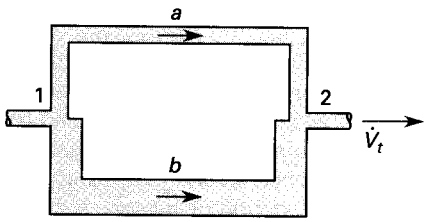

Figure 17.17 *Parallel Pipe System*

There are three principles that govern the distribution of flow between the two branches.

- The flow divides in such a manner as to make the head loss in each branch the same.

$$h_{f,a} = h_{f,b} \qquad 17.96$$

- The head loss between the two junctions is the same as the head loss in each branch.

$$h_{f,1-2} = h_{f,a} \qquad 17.97$$

- The total flow rate is the sum of the flow rates in the two branches.

$$\dot{V}_t = \dot{V}_a + \dot{V}_b \qquad 17.98$$

If the pipe diameters are known, Eq. 17.96 through Eq. 17.98 can be solved simultaneously for the branch velocities. In such problems, it is common to neglect minor losses, the velocity head, and the variation in the friction factor, f, with velocity.

If the parallel system has only two branches, the unknown branch flows can be determined by solving Eqs. 17.99 and 17.101 simultaneously.

$$\frac{f_a L_a \mathrm{v}_a^2}{2D_a g} = \frac{f_b L_b \mathrm{v}_b^2}{2D_b g} \qquad 17.99$$

$$\dot{V}_a + \dot{V}_b = \dot{V}_t \qquad 17.100$$

$$\left(\frac{\pi}{4}\right)\left(D_a^2 \mathrm{v}_a + D_b^2 \mathrm{v}_b\right) = \dot{V}_t \qquad 17.101$$

However, if the parallel system has three or more branches, it is easier to use the following iterative procedure. This procedure can be used for problems (a) where the flow rate is unknown but the pressure drop between the two junctions is known, or (b) where the total flow rate is known but the pressure drop and velocity are both unknown. In both cases, the solution iteratively determines the friction coefficients (f).

step 1: Solve the friction head loss (h_f) expression (either Darcy or Hazen-Williams) for velocity in each branch. If the pressure drop is known, first convert it to friction head loss.

$$\mathrm{v} = \sqrt{\frac{2Dgh_f}{fL}} \quad \text{[Darcy]} \qquad 17.102$$

$$v = \frac{0.355CD^{0.63}h_f^{0.54}}{L^{0.54}}$$

[Hazen-Williams; SI] 17.103(a)

$$v = \frac{0.550CD^{0.63}h_f^{0.54}}{L^{0.54}}$$

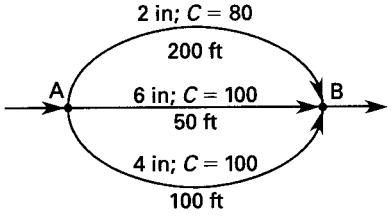
[Hazen-Williams; U.S.] 17.103(b)

step 2: Solve for the flow rate in each branch. If they are unknown, friction factors, f, must be assumed for each branch. The fully turbulent assumption provides a good initial estimate. (The value of k' will be different for each branch.)

$$\dot{V} = Av = A\sqrt{\frac{2Dgh_f}{fL}}$$

$$= k'\sqrt{hf} \quad \text{[Darcy]} \qquad 17.104$$

step 3: Write the expression for the conservation of flow. Calculate the friction head loss from the total flow rate. For example, for a three-branch system,



$$\dot{V}_t = \dot{V}_1 + \dot{V}_2 + \dot{V}_3$$

$$= (k_1' + k_2' + k_3')\sqrt{h_f} \qquad 17.105$$

step 4: Check the assumed values of the friction factor. Repeat as necessary.

Example 17.9

3.0 ft^3/sec of water enter the parallel pipe network shown. All pipes are schedule-40 steel with the nominal sizes shown. Minor losses are insignificant. What is the total friction head loss between junctions A and B?

Solution

step 1: Collect the pipe dimensions.

	2 in	4 in	6 in
flow area	0.0233 ft^2	0.0884 ft^2	0.2006 ft^2
diameter	0.1723 ft	0.3355 ft	0.5054 ft

Follow the procedure given in Sec. 29. Since the Hazen-Williams loss coefficients are given for each branch, the Hazen-Williams friction loss equation must be used.

$$h_f = \frac{3.022v^{1.85}L}{C^{1.85}D^{1.165}}$$

$$v = \frac{0.550CD^{0.63}h_f^{0.54}}{L^{0.54}}$$

The velocity (expressed in ft/sec) in the 2 in pipe branch is

$$v_{2\text{ in}} = \frac{(0.550)(80)(0.1723\text{ ft})^{0.63}h_f^{0.54}}{(200\text{ ft})^{0.54}}$$

$$= 0.831h_f^{0.54}$$

The velocities in the other two branches are

$$v_{6\text{ in}} = 4.327h_f^{0.54}$$

$$v_{4\text{ in}} = 2.299h_f^{0.54}$$

step 2: The flow rates are

$$\dot{V} = Av$$

$$\dot{V}_{2\text{ in}} = (0.0233\text{ ft}^2)(0.831)h_f^{0.54}$$

$$= 0.0194h_f^{0.54}$$

$$\dot{V}_{6\text{ in}} = (0.2006\text{ ft}^2)(4.327)h_f^{0.54}$$

$$= 0.8680h_f^{0.54}$$

$$\dot{V}_{4\text{ in}} = (0.0884\text{ ft}^2)(2.299)h_f^{0.54}$$

$$= 0.2032h_f^{0.54}$$

step 3: $\dot{V}_t = \dot{V}_{2\text{ in}} + \dot{V}_{6\text{ in}} + \dot{V}_{4\text{ in}}$

$$3\text{ ft}^3/\text{sec} = 0.0194h_f^{0.54} + 0.8680h_f^{0.54} + 0.2032h_f^{0.54}$$

The friction head loss is the same in all parallel branches.

$$3\text{ ft}^3/\text{sec} = (0.0194 + 0.8680 + 0.2032)h_f^{0.54}$$

$$h_f = 6.5\text{ ft}$$

30. MULTIPLE RESERVOIR SYSTEMS

In the *three-reservoir problem*, there are many possible choices for the unknown quantity (pipe length, diameter, head, flow rate, etc.). In all but the simplest cases, the solution technique is by trial and error based on conservation of mass and energy.

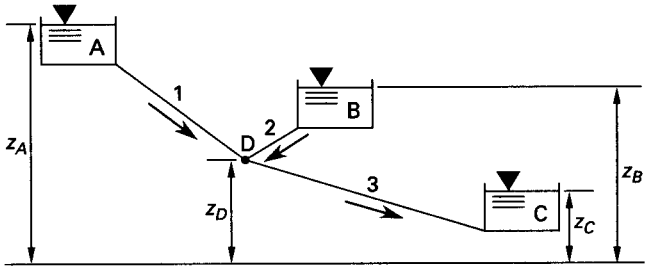


Figure 17.18 *Three-Reservoir System*

For simplification, velocity heads and minor losses are usually insignificant and can be neglected. However, the presence of a pump in any of the lines must be included in the solution procedure. This is most easily done by adding the pump head to the elevation of the reservoir feeding the pump. If the pump head is not known or depends on the flow rate, it must be determined iteratively as part of the solution procedure.

Case 1: Given all lengths, diameters, and elevations, find all flow rates.

Although an analytical solution method is possible, this type of problem is easily solved iteratively. The following procedure makes an initial estimate of a flow rate and uses it to calculate p_D. An alternative procedure is simply to make several estimates of p_D and calculate the corresponding values of flow rate.

step 1: Assume a reasonable value for $\dot{V}_1$. Calculate the corresponding friction loss, $h_{f,1}$. Use the Bernoulli equation to find the corresponding value of p_D. Disregard minor losses and velocity head.

$$\mathrm{v}_1 = \frac{\dot{V}_1}{A_1} \qquad 17.106$$

$$z_A = z_D + \frac{p_D}{\gamma} + h_{f,1} \qquad 17.107$$

step 2: Use the value of p_D to calculate $h_{f,2}$. Use the friction loss to determine v_2. Use v_2 to determine $\dot{V}_2$.

$$z_B = z_D + \frac{p_D}{\gamma} \pm h_{f,2} \qquad 17.108$$

$$\dot{V}_2 = \mathrm{v}_2 A_2 \qquad 17.109$$

If flow is out of reservoir B, $h_{f,2}$ should be added. If $z_D + (p_D/\gamma) > z_B$, flow will be into reservoir B. In this case, $h_{f,2}$ should be subtracted.

step 3: Similarly, use the value of p_D to calculate $h_{f,3}$. Use the friction loss to determine v_3. Use v_3 to determine $\dot{V}_3$.

$$z_C = z_D + \frac{p_D}{\gamma} - h_{f,2} \qquad 17.110$$

$$\dot{V}_3 = \mathrm{v}_3 A_3 \qquad 17.111$$

step 4: Check that $\dot{V}_1 \pm \dot{V}_2 = \dot{V}_3$. If it does not, repeat steps 1 through 4. After the second iteration, plot $\dot{V}_1 \pm \dot{V}_2 - \dot{V}_3$ versus $\dot{V}_1$. Interpolate or extrapolate the value of $\dot{V}_1$ that makes the difference zero.

Case 2: Given $\dot{V}_1$ and all lengths, diameters, and elevations except z_C, find z_C.

step 1: Calculate v_1.

$$\mathrm{v}_1 = \frac{\dot{V}_1}{A_1} \qquad 17.112$$

step 2: Calculate the corresponding friction loss, $h_{f,1}$. Use the Bernoulli equation to find the corresponding value of p_D. Disregard minor losses and velocity head.

$$z_A = z_D + \frac{p_D}{\gamma} + h_{f,1} \qquad 17.113$$

step 3: Use the value of p_D to calculate $h_{f,2}$. Use the friction loss to determine v_2. Use v_2 to determine $\dot{V}_2 A_2$.

$$z_B = z_D + \frac{p_D}{\gamma} \pm h_{f,2} \qquad 17.114$$

$$\dot{V}_2 = \mathrm{v}_2 A_2 \qquad 17.115$$

If flow is out of reservoir B, $h_{f,2}$ should be added. If $z_D + (p_D/\gamma) > z_B$, flow will be into reservoir B. In this case, $h_{f,2}$ should be subtracted.

step 4: $\dot{V}_3 = \dot{V}_1 \pm \dot{V}_2$ 17.116

step 5: $\mathrm{v}_3 = \dfrac{\dot{V}_3}{A_3}$ 17.117

step 6: Calculate $h_{f,3}$.

step 7: $z_C = z_D + \dfrac{p_D}{\gamma} - h_{f,3}$ 17.118

Case 3: Given $\dot{V}_1$, all lengths, all elevations, and all diameters except D_3, find D_3.

steps 1 through 4: Repeat steps 1 through 4 from case 2.

step 5: Calculate $h_{f,3}$ from

$$z_C = z_D + \frac{p_D}{\gamma} - h_{f,3} \qquad 17.119$$

step 6: Calculate D_3 from $h_{f,3}$.

Case 4: Given all lengths, diameters, and elevations except z_D, find z_D and all flow rates.

step 1: Calculate the head loss between each reservoir and junction D. Combine as many terms as possible into constant k'.

$$\dot{V} = A\mathrm{v} = A\sqrt{\frac{2Dgh_f}{f_L}} = k'\sqrt{h_f} \quad \text{[Darcy]} \qquad 17.120$$

$$\dot{V} = A\mathrm{v} = \frac{A(0.550)CD^{0.63}h_f^{0.54}}{L^{0.54}} = k'(h_f)^{0.54} \quad \text{[Hazen-Williams, U.S.]} \qquad 17.121$$

step 2: Assume that the flow direction in all three pipes is toward junction D. Write the conservation equation for junction D.

$$\dot{V}_{D,t} = \dot{V}_1 + \dot{V}_2 + \dot{V}_3 = 0 \qquad 17.122$$

$$k'_1\sqrt{h_{f,1}} + k'_2\sqrt{h_{f,2}} + k'_3\sqrt{h_{f,3}} = 0 \quad \text{[Darcy]} \qquad 17.123$$

$$k'_1(h_{f,1})^{0.54} + k'_2(h_{f,2})^{0.54} + k'_3(h_{f,3})^{0.54} = 0 \quad \text{[Hazen-Williams]} \qquad 17.124$$

step 3: Write the Bernoulli equation between each reservoir and junction D. Since $p_A = p_B = p_C = 0$, and $v_A = v_B = v_C = 0$, the friction loss in branch 1 is

$$h_{f,1} = z_A - z_D - \frac{p_D}{\gamma} \qquad 17.125$$

However, z_D and p_D can be combined since they are related constants in any particular situation. Define R_D as

$$R_D = z_D - \frac{p_D}{\gamma} \qquad 17.126$$

Then, the friction head losses in the branches are

$$h_{f,1} = z_A - R_D \qquad 17.127$$

$$h_{f,2} = z_B - R_D \qquad 17.128$$

$$h_{f,3} = z_C - R_D \qquad 17.129$$

step 4: Assume a value for R_D. Calculate the corresponding h_f values. Calculate the corresponding $\dot{V}_t$ value. Repeat until $\dot{V}_t$ converges to zero.

31. PIPE NETWORKS

Network flows in a *multiloop system* cannot be determined by any closed-form equation. Most real-world problems involving multiloop systems are analyzed on a computer. Computer programs are based on the *Hardy Cross method*, which can also be performed manually when there are only a few loops. In this method, flows in all of the branches are first assumed, and adjustments are made in consecutive iterations to the assumed flow.

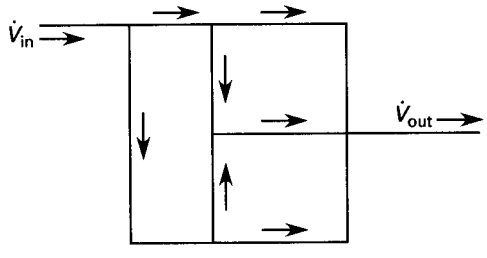

Figure 17.19 Multiloop System

The Hardy Cross method is based on the following principles.

Principle 17.1: Conservation: The flows entering a junction equal the flows leaving the junction.

Principle 17.2: The algebraic sum of head losses around any closed loop is zero.

The friction head loss has the form $h_f = K'\dot{V}^n$, with h_f having units of feet. (Note that k' used in Eq. 17.104 is equal to $\sqrt{1/K'}$.) The Darcy friction factor, f, is usually assumed to be the same in all parts of the network.

- For $\dot{V}$ in ft^3/sec, L in feet, and D in feet, the friction coefficient is

$$K' = \frac{0.02517fL}{D^5} \quad \text{[Darcy]} \qquad 17.130$$

$$K' = \frac{4.727L}{D^{4.8655}C^{1.85}} \quad \text{[Hazen-Williams]} \qquad 17.131$$

- For $\dot{V}$ in gal/min, L in feet, and d in inches, the friction coefficient is

$$K' = \frac{0.03109fL}{d^5} \quad \text{[Darcy]} \qquad 17.132$$

$$K' = \frac{10.44L}{d^{4.8655}C^{1.85}} \quad \text{[Hazen-Williams]} \qquad 17.133$$

- For $\dot{V}$ in gal/min, L in feet, and D in feet, the friction coefficient is

$$K' = \frac{1.251 \times 10^{-7}fL}{D^5} \quad \text{[Darcy]} \qquad 17.134$$

$$K' = \frac{5.862 \times 10^{-5}L}{D^{4.8655}C^{1.85}} \quad \text{[Hazen-Williams]} \qquad 17.135$$

- For $\dot{V}$ in MGD (millions of gallons per day), L in feet, and D in feet, the friction coefficient is

$$K' = \frac{0.06026fL}{D^5} \quad \text{[Darcy]} \qquad 17.136$$

$$K' = \frac{10.59L}{D^{4.8655}C^{1.85}} \quad \text{[Hazen-Williams]} \qquad 17.137$$

If $\dot{V}_a$ is the assumed flow in a pipe, the true value ($\dot{V}$) can be calculated from the difference (correction), δ.

$$\dot{V} = \dot{V}_a + \delta \qquad 17.138$$

The friction loss term for the assumed value and its correction can be expanded as a series. Since the correction is small, higher order terms can be omitted.

$$h_f = K'(\dot{V}_a + \delta)^n \approx K'\dot{V}_a^n + nK'\delta\dot{V}_a^{n-1} \qquad 17.139$$

From principle 17.2, the sum of the friction drops is zero around a loop. The correction, δ, is the same for all pipes in the loop and can be taken out of the summation. Since the loop closes on itself, all elevations can be omitted.

$$\sum h_f = \sum K'\dot{V}_a^n + n\delta \sum K'\dot{V}_a^{n-1} = 0 \quad 17.140$$

This equation can be solved for δ.

$$\delta = \frac{-\sum K'\dot{V}_a^n}{n\sum |K'\dot{V}_a^{n-1}|} = -\frac{\sum h_f}{n\sum \left|\frac{h_f}{\dot{V}_a}\right|} \quad 17.141$$

The Hardy Cross procedure is as follows.

step 1: Determine the value of n. For a Darcy head loss, the exponent is $n = 2$. For a Hazen-Williams loss, $n = 1.85$.

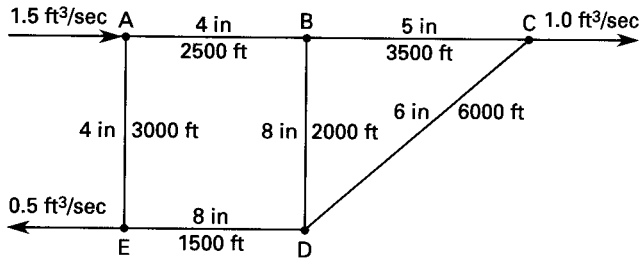
step 2: Arbitrarily select a positive direction (e.g., clockwise).

step 3: Label all branches and junctions in the network.

step 4: Separate the network into independent loops such that each branch is included in at least one loop.

step 5: Calculate K' for each branch in the network.

step 6: Assume consistent and reasonable flow rates and directions for each branch in the network.



step 7: Calculate the correction, δ, for each independent loop. (The numerator is the sum of head losses around the loop, taking signs into consideration.) It is not necessary for the loop to be at the same elevation everywhere. Disregard elevations. Since the loop closes on itself, all elevations can be omitted.

step 8: Apply the correction, δ, to each branch in the loop. The correction must be applied in the same sense to each branch in the loop. If clockwise has been taken as the positive direction, then δ is added to clockwise flows and subtracted from counterclockwise flows.

step 9: Repeat steps 7 and 8 until the correction is sufficiently small.

Example 17.10

A two-loop pipe network is shown. All junctions are at the same elevation. The Darcy friction factor is 0.02 for all pipes in the network. For convenience, use the nominal pipe sizes shown in the figure. Determine the flows in all branches.

Solution

step 1: The Darcy friction factor is given, so $n = 2$.

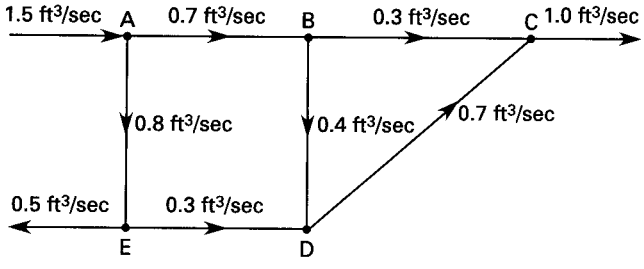
step 2: Select clockwise as the positive direction.

step 3: Use the junction letters in the illustration.

step 4: Two independent loops are needed. Work with loops ABDE and BCD. (Loop ABCDE could also be used but would be more complex than loop BCD.)

step 5: Work with branch AB.

$$D = \frac{4 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} = 0.3333 \text{ ft}$$



Use Eq. 17.130.

$$K'_{AB} = \frac{0.0252fL}{D^5} = \frac{(0.0252)(0.02)(2500 \text{ ft})}{(0.3333 \text{ ft})^5} = 306.2$$

Similarly,

$$K'_{BC} = 140.5$$
$$K'_{DC} = 96.8$$
$$K'_{BD} = 7.7$$
$$K'_{ED} = 5.7$$
$$K'_{AE} = 367.4$$

step 6: Assume the direction and flow rates shown.

step 7: Use Eq. 17.141.

$$\delta = \frac{-\sum K' \dot{V}_a^n}{n \sum |K' \dot{V}_a^{n-1}|}$$

$$\delta_{ABDE} = \frac{\begin{array}{r}-[(306.2)(0.7)^2 + (7.7)(0.4)^2 \\ -(5.7)(0.3)^2 - (367.4)(0.8)^2]\end{array}}{\begin{array}{r}2[(306.2)(0.7) + (7.7)(0.4) \\ +(5.7)(0.3) + (367.4)(0.8)]\end{array}}$$

$$= 0.08 \text{ ft}^3/\text{sec}$$

$$\delta_{BCD} = \frac{-[(140.5)(0.3)^2 - (96.8)(0.7)^2 - (7.7)(0.4)^2)]}{2[(140.5)(0.3) + (96.8)(0.7) + (7.7)(0.4)]}$$

$$= 0.16 \text{ ft}^3/\text{sec}$$

step 8: The corrected flows are

$$\dot{V}_{AB} = 0.7 \frac{\text{ft}^3}{\text{sec}} + 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.78 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{BC} = 0.3 \frac{\text{ft}^3}{\text{sec}} + 0.16 \frac{\text{ft}^3}{\text{sec}} = 0.46 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{DC} = 0.7 \frac{\text{ft}^3}{\text{sec}} - 0.16 \frac{\text{ft}^3}{\text{sec}} = 0.54 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{BD} = 0.4 \frac{\text{ft}^3}{\text{sec}} + 0.08 \frac{\text{ft}^3}{\text{sec}} - 0.16 \frac{\text{ft}^3}{\text{sec}}$$

$$= 0.32 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{ED} = 0.3 \frac{\text{ft}^3}{\text{sec}} - 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.22 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{AE} = 0.8 \frac{\text{ft}^3}{\text{sec}} - 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.72 \text{ ft}^3/\text{sec}$$

32. FLOW MEASURING DEVICES

A device that measures flow can be calibrated to indicate either velocity or volumetric flow rate. There are many methods available to obtain the flow rate. Some are indirect, requiring the use of transducers and solid-state electronics, and others can be evaluated using the Bernoulli equation. Some are more appropriate for one variety of fluid than others, and some are limited to specific ranges of temperature and pressure.

Table 17.7 categorizes a few common flow measurement methods. Many other methods and variations thereof exist, particularly for specialized industries. Some of the methods listed are so basic that only a passing mention will be made of them. Others, particularly those that can be analyzed with energy and mass conservation laws, will be covered in greater detail in subsequent sections.

Table 17.7 *Flow Measuring Devices*

I. direct (primary) measurements
  - positive-displacement meters
  - volume tanks
  - weight and mass scales

II. indirect (secondary) measurements
  - obstruction meters
    - flow nozzles
    - orifice plate meters
    - variable-area meters
    - venturi meters
  - velocity probes
    - direction sensing probes
    - pitot-static meters
    - pitot tubes
    - static pressure probes
  - miscellaneous methods
    - hot-wire meters
    - magnetic flow meters
    - mass flow meters
    - sonic flow meters
    - turbine and propeller meters

The utility meters used to measure gas and water usage are examples of *displacement meters.* Such devices are cyclical, fixed-volume devices with counters to record the numbers of cycles. Displacement devices are generally unpowered, drawing on only the pressure energy to overcome mechanical friction. Most configurations for positive-displacement pumps (e.g., reciprocating piston, helical screw, and nutating disk) have also been converted to measurement devices.

The venturi nozzle, orifice plate, and flow nozzle are examples of *obstruction meters.* These devices rely on a decrease in static pressure to measure the flow velocity. One disadvantage of these devices is that the pressure drop is proportional to the square of the velocity, limiting the range over which any particular device can be used.

An obstruction meter that somewhat overcomes the velocity range limitation is the *variable-area meter*, also known as a *rotameter*, illustrated in Fig. 17.20.[21] This device consists of a float (which is actually more dense than the fluid) and a transparent sight tube. With proper design, the effects of fluid density and viscosity can be minimized. The sight glass can be directly calibrated in volumetric flow rate, or the height of the float above the zero position can be used in a volumetric calculation.

[21] The rotameter has its own disadvantages, however. It must be installed vertically; the fluid cannot be opaque; and it is more difficult to manufacture for use with high-temperature, high-pressure fluids.

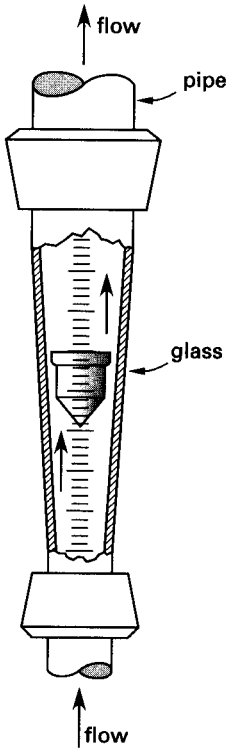


Figure 17.20 *Variable-Area Rotameter*

It is necessary to be able to measure static pressures in order to use obstruction meters and pitot-static tubes. In some cases, a *static pressure probe* is used. Figure 17.21 illustrates a simplified static pressure probe. In practice, such probes are sensitive to burrs and irregularities in the tap openings, orientation to the flow (i.e., *yaw*), and interaction with the pipe walls and other probes. A *direction-sensing probe* overcomes some of these problems.

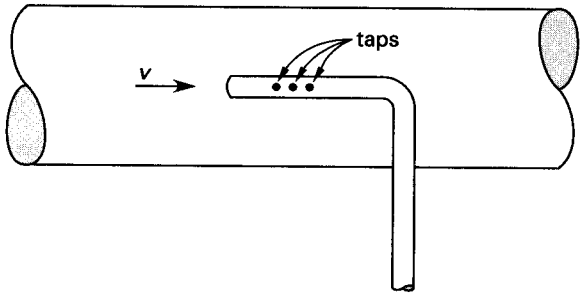

Figure 17.21 *Simple Static Pressure Probe*

A weather station *anemometer* used to measure wind velocity is an example of a simple *turbine meter*. Similar devices are used to measure the speed of a stream or river, in which case the name *current meter* may be used. Turbine meters are further divided into cup-type meters and propeller-type meters, depending on the orientation of the turbine axis relative to the flow direction. (The turbine axis and flow direction are parallel for propeller-type meters; they are perpendicular for cup-type meters.) Since the wheel motion is proportional to the flow velocity, the velocity is determined by counting the number of revolutions made by the wheel per unit time.

A more sophisticated turbine flowmeter uses a reluctance-type pickup coil to detect wheel motion. The permeability of a magnetic circuit changes each time a wheel blade passes the pole of a permanent magnet in the meter body. This change is detected to indicate velocity or flow rate.

A *hot-wire anemometer* measures velocity by determining the cooling effect of fluid (usually a gas) flowing over an electrically heated tungsten, platinum, or nickel wire. Cooling is primarily by convection; radiation and conduction are neglected. Circuitry can be used either to keep the current constant (in which case, the changing resistance is measured) or to keep the temperature constant (in which case, the changing current is measured). Additional circuitry can be used to compensate for thermal lag if the velocity changes rapidly.

A voltage proportional to the velocity will be generated when a conductor passes through a magnetic field.[22] This characteristic can be used to measure flow velocity if the fluid is electrically conductive. *Magnetic flowmeters* are ideal for measuring the flow of liquid metals, but variations of the device can also be used when the fluid is only slightly conductive. In some cases, precise quantities of conductive ions can be added to the fluid to permit measurement by this method.

In an *ultrasonic flowmeter*, two electric or magnetic transducers are placed a short distance apart on the outside of the pipe. One transducer serves as a transmitter of ultrasonic waves; the other transducer is a receiver. As an ultrasonic wave travels from the transmitter to the receiver, its velocity will be increased (or decreased) by the relative motion of the fluid. The phase shift between the fluid-carried waves and the waves passing through a stationary medium can be measured and converted to fluid velocity.

33. PITOT-STATIC GAUGE

Measurements from pitot tubes are used to determine total (stagnation) energy. Piezometer tubes and wall taps are used to measure static pressure energy. The difference between the total and static energies is the kinetic energy of the flow. Figure 17.22 illustrates a comparative method of directly measuring the velocity head for an incompressible fluid.

$$\frac{v^2}{2} = \frac{p_t - p_s}{\rho} = hg \qquad \text{[SI]} \quad 17.142(a)$$

$$\frac{v^2}{2g_c} = \frac{p_t - p_s}{\rho} = h \times \left(\frac{g}{g_c}\right) \qquad \text{[U.S.]} \quad 17.142(b)$$

$$v = \sqrt{2gh} \qquad 17.143$$

[22]The magnitude of this induced voltage is predicted by *Faraday's law*.

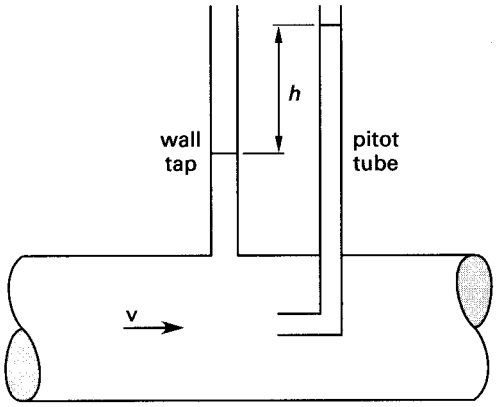

Figure 17.22 *Comparative Velocity Head Measurement*

The pitot tube and static pressure tap shown in Fig. 17.22 can be combined into a *pitot-static gauge*. In a pitot-static gauge, one end of the manometer is acted upon by the static pressure (also referred to as the *transverse pressure*). The other end of the manometer experiences the total pressure. The difference in elevations of the manometer fluid columns is the velocity head. This distance must be corrected if the density of the flowing fluid is significant.

$$\frac{v^2}{2} = \frac{p_t - p_s}{\rho} = \frac{h(\rho_m - \rho)g}{\rho} \quad \text{[SI]} \quad 17.144(a)$$

$$\frac{v^2}{2g_c} = \frac{p_t - p_s}{\rho} = \frac{h(\rho_m - \rho)}{\rho} \times \left(\frac{g}{g_c}\right) \quad \text{[U.S.]} \quad 17.144(b)$$

$$v = \sqrt{\frac{2gh(\rho_m - \rho)}{\rho}} \quad 17.145$$

Another correction, which is seldom made, is to multiply the velocity calculated from Eq. 17.145 by C_I, the *coefficient of the instrument*. Since the flow past the pitot-static tube is slightly faster than the free-fluid velocity, the static pressure measured will be slightly lower than the true value. This makes the indicated velocity slightly higher than the true value. C_I, a number close to but less than 1.0, corrects for this.

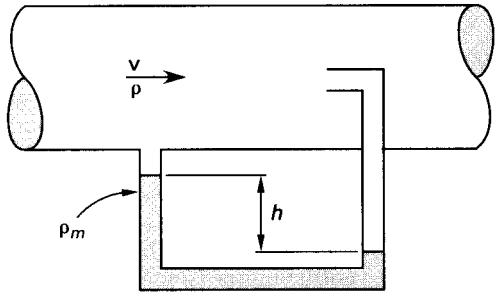

Figure 17.23 *Pitot-Static Gauge*

A pitot-static tube indicates the velocity at only one point in a pipe. If the flow is laminar, and if the pitot-static tube is in the center of the pipe, v_{max} will be determined. The average velocity, however, will be only half the maximum value.

Pitot tube measurements are sensitive to the condition of the opening and errors in installation alignment. The *yaw angle* (i.e., the acute angle between the pitot tube axis and the flow streamline) should be zero.

Example 17.11

Water (62.4 lbm/ft^3; $\rho = 1000$ kg/m^3) is flowing through a pipe. A pitot-static gauge registers 3.0 in (0.076 m) of mercury. What is the velocity of the water in the pipe?

SI Solution

The density of mercury is $\rho = 13\,580$ kg/m^3. The velocity can be calculated directly from Eq. 17.145.

$$v = \sqrt{\frac{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(0.076\ \text{m}) \times \left(13\,580\ \frac{\text{kg}}{\text{m}^3} - 1000\ \frac{\text{kg}}{\text{m}^3}\right)}{1000\ \frac{\text{kg}}{\text{m}^3}}}$$

$$= 4.33\ \text{m/s}$$

Customary U.S. Solution

The density of mercury is $\rho = 848.6$ lbm/ft^3.

From Eq. 17.145,

$$v = \sqrt{\frac{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)\left(\frac{3}{12}\ \text{ft}\right) \times \left(848.6\ \frac{\text{lbm}}{\text{ft}^3} - 62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)}{62.4\ \frac{\text{lbm}}{\text{ft}^3}}}$$

$$= 14.24\ \text{ft/sec}$$

34. VENTURI METER

Figure 17.24 illustrates a simple *venturi*. (Sometimes the venturi is called a *converging-diverging nozzle*.) This flow measuring device can be inserted directly into a pipeline. Since the diameter changes are gradual, there is very little friction loss.[23] Static pressure measurements are taken at the throat and upstream of the diameter change. These measurements are traditionally made by manometer.

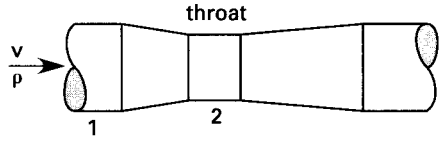

Figure 17.24 *Venturi Meter*

[23]The actual friction loss is approximately 10% of the pressure difference $p_1 - p_2$.

The analysis of *venturi meter* performance is relatively simple. The traditional derivation of upstream velocity starts by assuming a horizontal orientation and frictionless, incompressible, and turbulent flow. Then the Bernoulli equation is written for points 1 and 2. Equation 17.146 shows that the static pressure decreases as the velocity increases. This is known as the *venturi effect*.

$$\frac{v_1^2}{2} + \frac{p_1}{\rho} = \frac{v_2^2}{2} + \frac{p_2}{\rho} \qquad \text{[SI]} \quad 17.146(a)$$

$$\frac{v_1^2}{2g_c} + \frac{p_1}{\rho} = \frac{v_2^2}{2g_c} + \frac{p_2}{\rho} \qquad \text{[U.S.]} \quad 17.146(b)$$

The two velocities are related by the continuity equation.

$$A_1 v_1 = A_2 v_2 \qquad 17.147$$

Combining Eqs. 17.146 and 17.147 and eliminating the unknown v_1 produces an expression for the throat velocity. Also, a *coefficient of velocity* is used to account for the small effect of friction. (C_v is very close to 1.0, usually 0.98 or 0.99.)

$$v_2 = C_v v_{2,\text{ideal}}$$

$$= \left[\frac{C_v}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}}\right]\sqrt{\frac{2(p_1 - p_2)}{\rho}} \qquad \text{[SI]} \quad 17.148(a)$$

$$v_2 = \left[\frac{C_v}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}}\right]\sqrt{\frac{2g_c(p_1 - p_2)}{\rho}} \qquad \text{[U.S.]} \quad 17.148(b)$$

The *velocity of approach factor*, F_{va}, also known as the *meter constant*, is the reciprocal of the denominator of Eq. 17.148. The *beta ratio* can be incorporated into the formula for F_{va}.

$$\beta = \frac{D_2}{D_1} \qquad 17.149$$

$$F_{va} = \frac{1}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} = \frac{1}{\sqrt{1 - \beta^4}} \qquad 17.150$$

If a manometer is used to measure the pressure difference directly, Eq. 17.148 can be rewritten in terms of the manometer fluid reading.

$$v_2 = \left(\frac{C_v}{\sqrt{1 - \beta^4}}\right)\sqrt{\frac{2g(\rho_m - \rho)h}{\rho}}$$

$$= C_v F_{va}\sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \qquad 17.151$$

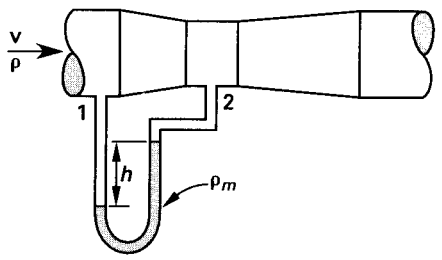

Figure 17.25 *Venturi Meter with Manometer*

The flow rate through a venturi meter can be calculated from the throat area. There is an insignificant amount of contraction of the flow as it passes through the throat, and the *coefficient of contraction* is seldom encountered in venturi meter work. The *coefficient of discharge* ($C_d = C_c C_v$) is quoted, nevertheless. Values of C_d range from slightly less than 0.90 to over 0.99, depending on the Reynolds number. C_d is seldom less than 0.95 for turbulent flow.

$$\dot{V} = C_d A_2 v_{2,\text{ideal}} \qquad 17.152$$

The product $C_d F_{va}$ is known as the *coefficient of flow* or *flow coefficient*, not to be confused with the coefficient of discharge.[24] This factor is used for convenience, since it combines the losses with the meter constant.

$$C_f = C_d F_{va} = \frac{C_d}{\sqrt{1 - \beta^4}} \qquad 17.153$$

$$\dot{V} = C_f A_2\sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \qquad 17.154$$

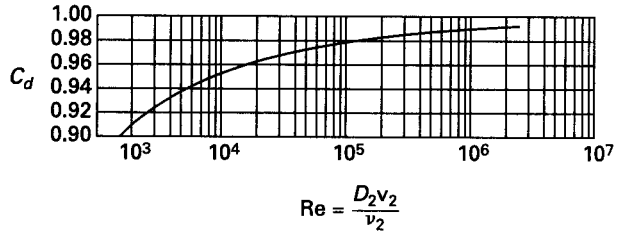

Figure 17.26 *Typical Venturi Meter Discharge Coefficients*

35. ORIFICE METER

The *orifice meter* (or *orifice plate*) is used more frequently than the venturi meter to measure flow rates in small pipes. It consists of a thin or sharp-edged plate with a central, round hole through which the fluid flows. Such a plate is easily clamped between two flanges in an existing pipeline.

[24] Some writers use the symbol K for the flow coefficient.

While (for small pipes) the orifice meter may consist of a thin plate without significant thickness, various types of bevels and rounded edges are also used with thicker plates. There is no significant difference in the analysis procedure between "flat plate," "sharp-edged," or "square-edged" orifice meters. Any effect that the orifice edges have is accounted for in the discharge and flow coefficient correlations. Similarly, the direction of the bevel will affect the coefficients, but not the analysis method.

As with the venturi meter, pressure taps are used to obtain the static pressure upstream of the orifice plate and at the *vena contracta* (i.e., at the point of minimum pressure).[25] A differential manometer connected to the two taps conveniently indicates the difference in static pressures.

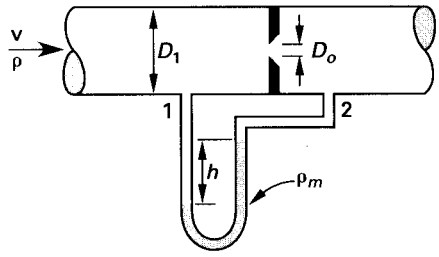

Figure 17.27 *Orifice Meter with Differential Manometer*

The derivation of the governing equations for an orifice meter is similar to that of the venturi meter. (The obvious falsity of assuming frictionless flow through the orifice is corrected by the coefficient of discharge.) The major difference is that the coefficient of contraction is taken into consideration in writing the mass continuity equation, since the pressure is measured at the vena contracta, not at the orifice.

$$A_2 = C_c A_o \qquad 17.155$$

$$v_o = \left[\frac{C_v}{\sqrt{1 - \left(\frac{C_c A_o}{A_1}\right)^2}}\right]\sqrt{\frac{2(p_1 - p_2)}{\rho}} \quad \text{[SI]} \qquad 17.156(a)$$

$$v_o = \left[\frac{C_v}{\sqrt{1 - \left(\frac{C_c A_o}{A_1}\right)^2}}\right]\sqrt{\frac{2g_c(p_1 - p_2)}{\rho}} \quad \text{[U.S.]} \qquad 17.156(b)$$

If a manometer is used to indicate the differential pressure $p_1 - p_2$, the velocity at the vena contracta can be calculated from Eq. 17.157.

$$v_o = \left[\frac{C_v}{\sqrt{1 - \left(\frac{C_c A_o}{A_1}\right)^2}}\right]\sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \qquad 17.157$$

Although the orifice meter is simpler and less expensive than a venturi meter, its discharge coefficient is much less than that of a venturi meter. C_d usually ranges from 0.55 to 0.75, with values of 0.60 and 0.61 often being quoted. (The coefficient of contraction has a large effect, since $C_d = C_v C_c$.) Also, its pressure recovery is poor (i.e., there is a permanent pressure reduction), and it is susceptible to inaccuracies from wear and abrasion.[26]

The velocity of approach factor, F_{va}, for an orifice meter is defined differently than for a venturi meter, since it takes into consideration the contraction of the flow. However, the velocity of approach factor is still combined with the coefficient of discharge into the flow coefficient, C_f. Figure 17.28 illustrates how the flow coefficient varies with the area ratio and the Reynolds number.

$$F_{va} = \frac{1}{\sqrt{1 - \left(\frac{C_c A_o}{A_1}\right)^2}} \qquad 17.158$$

$$C_f = C_d F_{va} \qquad 17.159$$

[25] Calibration of the orifice meter is sensitive to tap placement. Upstream taps are placed between one-half and two pipe diameters upstream from the orifice. (An upstream distance of one pipe diameter is often quoted and used.) There are three tap-placement options: flange, vena contracta, and standardized. Flange taps are used with prefabricated orifice meters that are inserted (by flange bolting) in pipes. If the location of the vena contracta is known, a tap can be placed there. However, the location of the vena contracta depends on the diameter ratio $\beta = D_o/D$ and varies from approximately 0.4 to 0.7 pipe diameters downstream. Due to the difficulty of locating the vena contracta, the standardized $1D$-$^1/_2D$ configuration is often used. The upstream tap is one diameter before the orifice; the downstream tap is one-half diameter after the orifice. Since approaching flow should be stable and uniform, care must be taken not to install the orifice meter less than approximately five diameters after a bend or elbow.

[26] The actual permanent pressure loss varies from 40 to 90% of the differential pressure. The loss depends on the diameter ratio $\beta = D_o/D_1$, and is not particularly sensitive to the Reynolds number for turbulent flow. For $\beta = 0.5$, the loss is 73% of the measured pressure difference, $p_1 - p_2$. This decreases to approximately 56% of the pressure difference when $\beta = 0.65$ and to 38% when $\beta = 0.8$. For any diameter ratio, the pressure drop coefficient, K, in multiples of the orifice velocity head is

$$K = \frac{1 - \beta^2}{C_f^2}$$

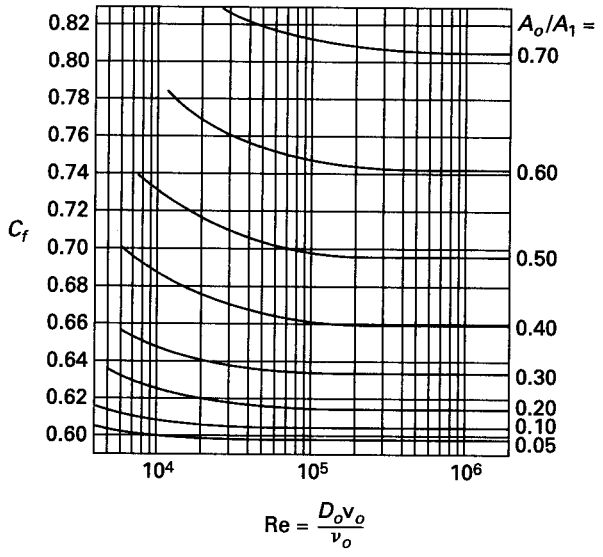

Figure 17.28 *Typical Flow Coefficients for Orifice Plates*

The flow rate through an orifice meter is given by Eq. 17.160.

$$\dot{V} = C_f A_o \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \qquad 17.160$$

Example 17.12

150°F water ($\rho = 61.2$ lbm/ft^3) flows in an 8 in schedule-40 steel pipe at the rate of 2.23 ft^3/sec. A sharp-edged orifice with a 7 in diameter hole is placed in the line. A mercury differential manometer is used to record the pressure difference. If the orifice has a flow coefficient, C_f, of 0.62, what deflection in inches of mercury is observed? (Mercury has a density of 848.6 lbm/ft^3.)

Solution

The orifice area is

$$A_o = \frac{\pi}{4} D_o^2 = \left(\frac{\pi}{4}\right) \left(\frac{7 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}\right)^2$$

$$= 0.2673 \text{ ft}^2$$

Equation 17.160 is solved for h.

$$h = \frac{\dot{V}^2 \rho}{2gC_f^2 A_o^2 (\rho_m - \rho)}$$

$$= \frac{\left(2.23 \frac{\text{ft}^3}{\text{sec}}\right)^2 \left(61.2 \frac{\text{lbm}}{\text{ft}^3}\right) \left(12 \frac{\text{in}}{\text{ft}}\right)}{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(0.62)^2 \times (0.2673 \text{ ft}^2)^2 \left(848.6 \frac{\text{lbm}}{\text{ft}^3} - 61.2 \frac{\text{lbm}}{\text{ft}^3}\right)}$$

$$= 2.62 \text{ in}$$

36. FLOW NOZZLE

A typical flow nozzle is illustrated in Fig. 17.29. This device consists only of a converging section. It is somewhat between an orifice plate and a venturi meter in performance, possessing some of the advantages and disadvantages of each. The venturi performance equations can be used for the flow nozzle.

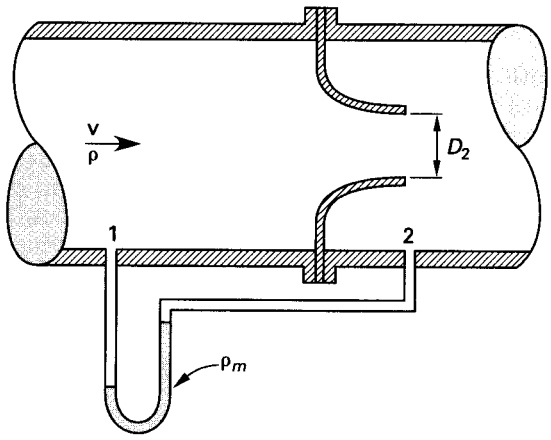

Figure 17.29 *Flow Nozzle*

The geometry of the nozzle entrance is chosen to prevent separation of the fluid from the wall. The converging portion and the subsequent parallel section keep the coefficients of velocity and contraction close to 1.0. However, the absence of a diffuser section disrupts the orderly return of fluid to its original condition. The permanent pressure drop is more similar to that of the orifice meter than the venturi meter.

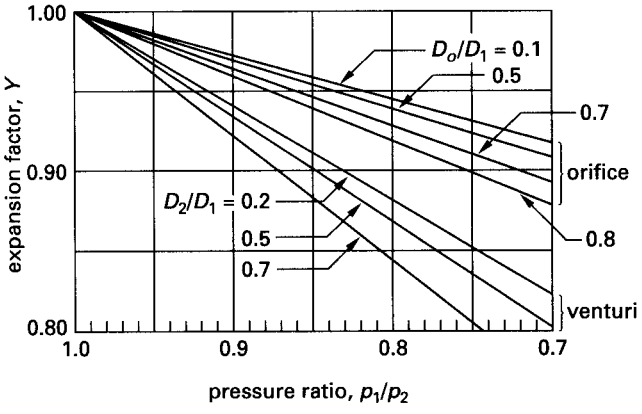
Since the nozzle geometry greatly affects the performance, values of C_d and C_f have been established for only a limited number of specific proprietary nozzles.[27]

37. FLOW MEASUREMENTS OF COMPRESSIBLE FLUIDS

Volume measurements of compressible fluids (i.e., gases) are not very meaningful. The volume of a gas will depend on its temperature and pressure. For that reason, flow quantities of gases discharged should be stated as mass flow rates.

$$\dot{m} = \rho_2 A_2 v_2 \qquad 17.161$$

Equation 17.161 requires that the velocity and area be measured at the same point. More important, the density must be measured at that point, as well. However, it is common practice in flow measurement work to use the density of the upstream fluid at position 1. (Note that this is not the stagnation density.)



[27]Some of the proprietary nozzles for which detailed performance data exist are the ASME long-radius nozzle (low-β and high-β series) and the International Standards Association (ISA) nozzle (German standard nozzle).

The significant error introduced by this simplification is corrected by the use of an *expansion factor*, Y. For venturi meters and flow nozzles, values of the expansion factor are generally calculated theoretical values. Values of Y are determined experimentally for orifice plates.

$$\dot{m} = Y\rho_1 A_2 v_2 \qquad 17.162$$

Derivation of the theoretical formula for the expansion factor for venturi meters and flow nozzles is based on thermodynamic principles and an assumption of adiabatic flow.

$$Y = \sqrt{\frac{(1-\beta^4)\left[\left(\frac{p_2}{p_1}\right)^{\frac{2}{k}} - \left(\frac{p_2}{p_1}\right)^{\frac{k+1}{k}}\right]}{\left(\frac{k-1}{k}\right)\left(1-\frac{p_2}{p_1}\right)\left[1-\beta^4\left(\frac{p_2}{p_1}\right)^{\frac{2}{k}}\right]}} \qquad 17.163$$

Transport Processes, 3rd ed., by Geankoplis, C. J., © 1993. Reprinted by permission of Prentice-Hall, Inc., Upper Saddle River, NJ.

Figure 17.30 *Approximate Expansion Factors*

Once the expansion factor is known, it can be used with the standard flow rate ($\dot{V}$) equations for venturi meters, flow nozzles, and orifice meters. For example, for a venturi meter, the mass flow rate would be calculated from Eq. 17.164.

$$\dot{m} = \left(\frac{C_d A_2 Y}{\sqrt{1-\beta^4}}\right)\sqrt{2\rho_1(p_1-p_2)} \qquad \text{[SI]} \quad 17.164(a)$$

$$\dot{m} = \left(\frac{C_d A_2 Y}{\sqrt{1-\beta^4}}\right)\sqrt{2g_c\rho_1(p_1-p_2)} \qquad \text{[U.S.]} \quad 17.164(b)$$

38. IMPULSE-MOMENTUM PRINCIPLE

(The convention of this section is to make F and x positive when they are directed toward the right. F and y are positive when directed upward. Also, the fluid is assumed to flow horizontally from left to right, and it has no initial y-component of velocity.)

The *momentum*, $\mathbf{P}$ (also known as *linear momentum* to distinguish it from *angular momentum*, which is not considered here), of a moving object is a vector quantity defined as the product of the object's mass and velocity.[28]

$$\mathbf{P} = m\mathbf{v} \qquad \text{[SI]} \quad 17.165(a)$$

$$\mathbf{P} = \frac{m\mathbf{v}}{g_c} \qquad \text{[U.S.]} \quad 17.165(b)$$

The *impulse*, I, of a constant force is calculated as the product of the force's magnitude and the length of time the force is applied.

$$\mathbf{I} = \mathbf{F}\Delta t \qquad 17.166$$

The *impulse-momentum principle* states that the impulse applied to a body is equal to the change in momentum. (This is also known as the *law of conservation of momentum*, even though fluid momentum is not always conserved.) Equation 17.167 is one way of stating Newton's second law.

$$\mathbf{I} = \Delta\mathbf{P} \qquad 17.167$$

$$F\Delta t = m\Delta v = m(v_2 - v_1) \qquad \text{[SI]} \quad 17.168(a)$$

$$F\Delta t = \frac{m\Delta v}{g_c} = \frac{m(v_2 - v_1)}{g_c} \qquad \text{[U.S.]} \quad 17.168(b)$$

For fluid flow, there is a mass flow rate, $\dot{m}$, but no mass per se. Since $\dot{m} = m/\Delta t$, the impulse-momentum equation can be rewritten as follows.

$$F = \dot{m}\Delta v \qquad \text{[SI]} \quad 17.169(a)$$

$$F = \frac{\dot{m}\Delta v}{g_c} \qquad \text{[U.S.]} \quad 17.169(b)$$

Equation 17.169 calculates the constant force required to accelerate or retard a fluid stream. This would occur when fluid enters a reduced or enlarged flow area. If the flow area decreases, for example, the fluid will be accelerated by a wall force up to the new velocity. Ultimately, this force must be resisted by the pipe supports.

As Eq. 17.169 illustrates, fluid momentum is not always conserved, since it is generated by the external force, F. Examples of external forces are gravity (considered zero for horizontal pipes), gage pressure, friction, and turning forces from walls and vanes. Only if these external forces are absent is fluid momentum conserved.

Since force is a vector, it can be resolved into its x- and y-components of force.

$$F_x = \dot{m}\Delta v_x \qquad 17.170$$

$$F_y = \dot{m}\Delta v_y \qquad 17.171$$

[28]The symbol B is also used for momentum. In many texts, however, momentum is given no symbol at all.

If the flow is initially at velocity v but is directed through an angle θ with respect to the original direction, the x- and y-components of velocity can be calculated from Eqs. 17.172 and 17.173.

$$\Delta v_x = v(\cos\theta - 1) \qquad 17.172$$

$$\Delta v_y = v \sin\theta \qquad 17.173$$

Since F and v are vector quantities and Δt and m are scalars, F must have the same direction as $v_2 - v_1$. This provides an intuitive method of determining the direction in which the force acts. Essentially, one needs to ask, "In which direction must the force act in order to push the fluid stream into its new direction?" (The force, F, is the force on the fluid. The force on the pipe walls or pipe supports has the same magnitude but is opposite in direction.)

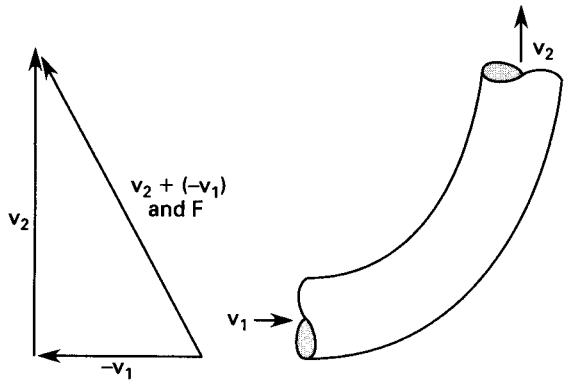


Figure 17.31 *Force on a Confined Fluid Stream*

If a jet is completely stopped by a flat plate placed perpendicular to its flow, then $\theta = 90°$ and $\Delta v_x = -v$. If a jet is turned around so that it ends up returning to where it originated, then $\theta = 180°$ and $\Delta v_x = -2v$. Notice that a positive Δv indicates an increase in velocity. A negative Δv indicates a decrease in velocity.

39. JET PROPULSION

A basic application of the impulse-momentum principle is the analysis of jet propulsion. Air enters a jet engine and is mixed with a small amount of jet fuel. The air and fuel mixture is compressed and ignited, and the exhaust products leave the engine at a greater velocity than was possessed by the original air. The change in momentum of the air produces a force on the engine.

The governing equation for a jet engine is Eq. 17.174. In the special case of VTOL (vertical takeoff and landing) aircraft, there will also be a y-component of force. The mass of the jet fuel is small compared with the air mass, and the fuel mass is commonly disregarded.

$$F_x = \dot{m}(v_2 - v_1) \qquad 17.174$$

$$F_x = \dot{V}_2\rho_2 v_2 - \dot{V}_1\rho_1 v_1 \quad [SI] \qquad 17.175(a)$$

$$F_x = \frac{\dot{V}_2\rho_2 v_2 - \dot{V}_1\rho_1 v_1}{g_c} \quad [U.S.] \qquad 17.175(b)$$

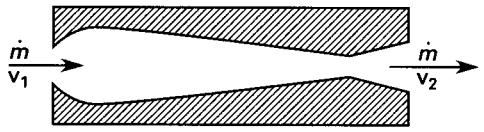

Figure 17.32 *Jet Engine*

40. OPEN JET ON A VERTICAL FLAT PLATE

Figure 17.33 illustrates an open jet on a vertical flat plate. The fluid approaches the plate with no vertical component of velocity; it leaves the plate with no horizontal component of velocity. (This is another way of saying there is no splash-back.) Thus, all of the velocity in the x-direction is canceled. (The minus sign in Eq. 17.176 indicates that the force is opposite the initial velocity direction.)

$$\Delta v = -v \qquad 17.176$$

$$F_x = -\dot{m}v \quad [SI] \qquad 17.177(a)$$

$$F_x = \frac{-\dot{m}v}{g_c} \quad [U.S.] \qquad 17.177(b)$$

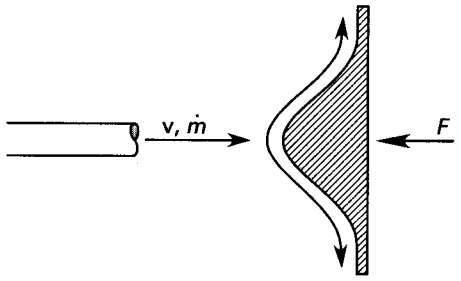

Figure 17.33 *Jet on a Vertical Plate*

Since the flow is divided, half going up and half going down, the net velocity change in the y-direction is zero. There is no force in the y-direction on the fluid.

41. OPEN JET ON A HORIZONTAL FLAT PLATE

If a jet of fluid is directed upward, its velocity will decrease due to the effect of gravity. The force exerted on the fluid by the plate will depend on the fluid velocity at the plate surface, v_y, not the original jet velocity, v_o. All of this velocity is canceled. Since the flow divides evenly in both horizontal directions ($\Delta v_x = 0$), there is no force component in the x-direction.

$$v_y = \sqrt{v_o^2 - 2gh} \qquad 17.178$$

$$\Delta v_y = -\sqrt{v_o^2 - 2gh} \qquad 17.179$$

$$F_y = -\dot{m}\sqrt{v_o^2 - 2gh} \quad [SI] \qquad 17.180(a)$$

$$F_y = \frac{-\dot{m}\sqrt{v_o^2 - 2gh}}{g_c} \quad [U.S.] \qquad 17.180(b)$$

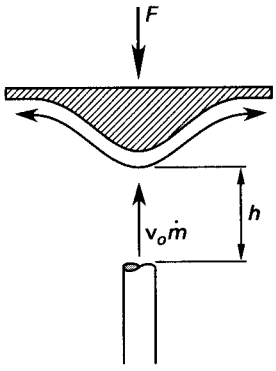

Figure 17.34 *Open Jet on a Horizontal Plate*

42. OPEN JET ON AN INCLINED PLATE

An open jet will be diverted both up and down a stationary, inclined plate, as shown in Fig. 17.35. In the absence of friction, the velocity in each diverted flow will be v, the same as in the approaching jet. The fractions f_1 and f_2 of the jet that are diverted up and down can be found from Eq. 17.181 through Eq. 17.184.

$$f_1 = \frac{1 + \cos\theta}{2} \qquad 17.181$$

$$f_2 = \frac{1 - \cos\theta}{2} \qquad 17.182$$

$$f_1 - f_2 = \cos\theta \qquad 17.183$$

$$f_1 + f_2 = 1.0 \qquad 17.184$$

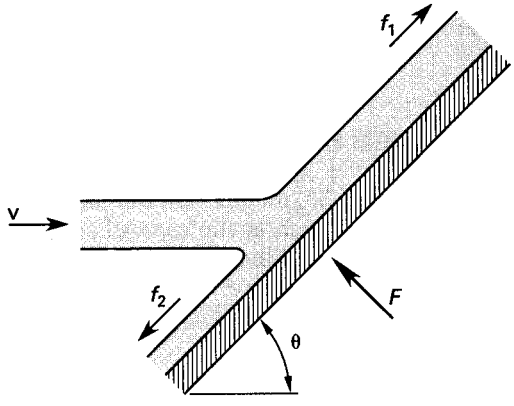

Figure 17.35 *Open Jet on an Inclined Plate*

If the flow along the plate is frictionless, there will be no force component parallel to the plate. The force perpendicular to the plate is given by Eq. 17.185.

$$F = \dot{m}V \sin\theta \qquad \text{[SI]} \qquad 17.185(a)$$

$$F = \frac{\dot{m}V \sin\theta}{g_c} \qquad \text{[U.S.]} \qquad 17.185(b)$$

43. OPEN JET ON A SINGLE STATIONARY BLADE

Figure 17.36 illustrates a fluid jet being turned through an angle θ by a stationary blade (also called a *vane*). It is common to assume that $|v_2| = |v_1|$, although this will not be strictly true if friction between the blade and fluid is considered. Since the fluid is both retarded (in the x-direction) and accelerated (in the y-direction), there will be two components of force on the fluid.

$$\Delta v_x = v_2 \cos\theta - v_1 \qquad 17.186$$

$$\Delta v_y = v_2 \sin\theta \qquad 17.187$$

$$F_x = \dot{m}\,(v_2 \cos\theta - v_1) \qquad \text{[SI]} \qquad 17.188(a)$$

$$F_x = \frac{\dot{m}\,(v_2 \cos\theta - v_1)}{g_c} \qquad \text{[U.S.]} \qquad 17.188(b)$$

$$F_y = \dot{m}v_2 \sin\theta \qquad \text{[SI]} \qquad 17.189(a)$$

$$F_y = \frac{\dot{m}v_2 \sin\theta}{g_c} \qquad \text{[U.S.]} \qquad 17.189(b)$$

$$F = \sqrt{F_x^2 + F_y^2} \qquad 17.190$$

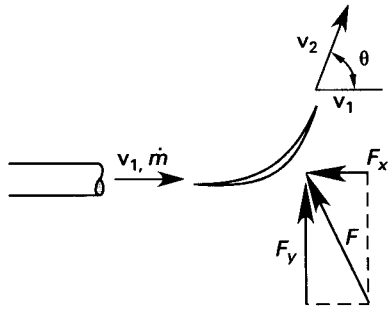

Figure 17.36 *Open Jet on a Stationary Blade*

44. OPEN JET ON A SINGLE MOVING BLADE

If a blade is moving away at velocity v_b from the source of the fluid jet, only the *relative velocity difference* between the jet and blade produces a momentum change. Furthermore, not all of the fluid jet overtakes the moving blade. The equations used for the single stationary blade can be used by substituting $(v - v_b)$ for v and by using the effective mass flow rate, m_{eff}.

$$\Delta v_x = (v - v_b)(\cos\theta - 1) \qquad 17.191$$

$$\Delta v_y = (v - v_b)(\sin\theta) \qquad 17.192$$

$$\dot{m}_{\text{eff}} = \left(\frac{v - v_b}{v}\right)\dot{m} \qquad 17.193$$

$$F_x = \dot{m}_{\text{eff}}(v - v_b)(\cos\theta - 1) \qquad \text{[SI]} \qquad 17.194(a)$$

$$F_x = \frac{\dot{m}_{\text{eff}}(v - v_b)(\cos\theta - 1)}{g_c} \qquad \text{[U.S.]} \qquad 17.194(b)$$

$$F_y = \dot{m}_{\text{eff}}(v - v_b)(\sin\theta) \qquad \text{[SI]} \qquad 17.195(a)$$

$$F_y = \frac{\dot{m}_{\text{eff}}(v - v_b)(\sin\theta)}{g_c} \qquad \text{[U.S.]} \qquad 17.195(b)$$

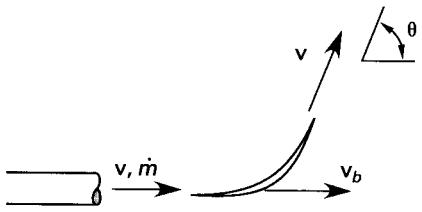

Figure 17.37 *Open Jet on a Moving Blade*

45. OPEN JET ON A MULTIPLE-BLADED WHEEL

An *impulse turbine* consists of a series of blades (buckets or vanes) mounted around a wheel. The tangential velocity of the blades is approximately parallel to the jet. The effective mass flow rate, $\dot{m}_{\text{eff}}$, used in calculating the reaction force is the full discharge rate, since when one blade moves away from the jet, other blades will have moved into position. Thus, all of the fluid discharged is captured by the blades. Equations 17.194 and 17.195 are applicable if the total flow rate is used.

$$v_b = \frac{\text{rpm} \times 2\pi r}{60} = \omega r \qquad 17.196$$

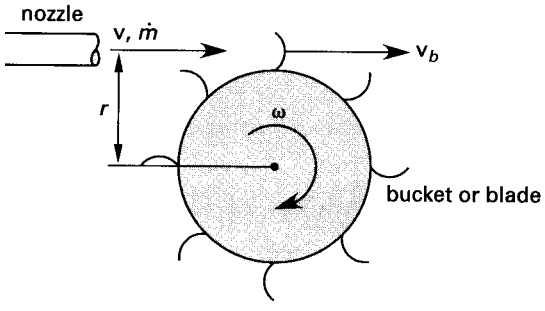

Figure 17.38 *Impulse Turbine*

46. IMPULSE TURBINE POWER

The total power potential of a fluid jet can be calculated from the kinetic energy of the jet and the mass flow rate.[29] (This neglects the pressure energy, which is small by comparison.)

$$P_{\text{jet}} = \frac{\dot{m}v^2}{2} \qquad \text{[SI]} \quad 17.197(a)$$

$$P_{\text{jet}} = \frac{\dot{m}v^2}{2g_c} \qquad \text{[U.S.]} \quad 17.197(b)$$

The power transferred from a fluid jet to the blades of a turbine is calculated from the x-component of force on the blades. The y-component of force does no work.

[29]The full jet discharge is used in this section. If only a single blade is involved, the effective mass flow rate, $\dot{m}_{\text{eff}}$, must be used.

$$P = F_x v_b \qquad 17.198$$

$$P = \dot{m}v_b\,(v - v_b)(1 - \cos\theta) \qquad \text{[SI]} \quad 17.199(a)$$

$$P = \frac{\dot{m}v_b\,(v - v_b)(1 - \cos\theta)}{g_c} \qquad \text{[U.S.]} \quad 17.199(b)$$

The maximum theoretical blade velocity is the velocity of the jet: $v_b = v$. This is known as the *runaway speed* and can only occur when the turbine is unloaded. If Eq. 17.199 is maximized with respect to v_b, however, the maximum power will be found to occur when the blade is traveling at half of the jet velocity: $v_b = v/2$. The power (force) is also affected by the deflection angle of the blade. Power is maximized when $\theta = 180°$. Figure 17.39 illustrates the relationship between power and the variables θ and v_b.

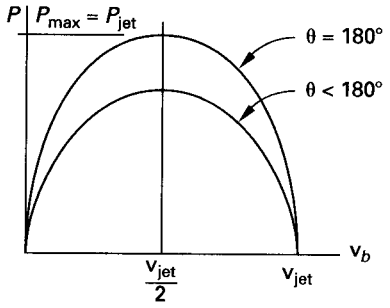

Figure 17.39 *Turbine Power*

Putting $\theta = 180°$ and $v_b = v/2$ into Eq. 17.199 results in $P_{\text{max}} = \dot{m}v^2/2$, which is the same as P_{jet} in Eq. 17.193. If the machine is 100% efficient, 100% of the jet power can be transferred to the machine.

47. CONFINED STREAMS IN PIPE BENDS

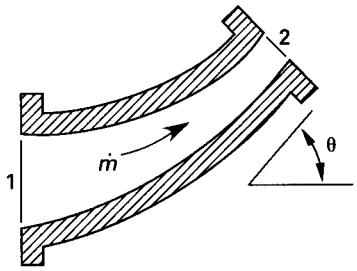
As presented in Sec. 38, momentum can also be changed by pressure forces. Such is the case when fluid enters a pipe fitting or bend. Since the fluid is confined, the forces due to static pressure must be included in the analysis. (The effects of gravity and friction are neglected.)

$$F_x = p_2A_2\ \cos\theta - p_1A_1 + \dot{m}(v_2\ \cos\theta - v_1) \qquad \text{[SI]} \quad 17.200(a)$$

$$F_x = p_2A_2\ \cos\theta - p_1A_1 + \frac{\dot{m}(v_2\ \cos\theta - v_1)}{g_c} \qquad \text{[U.S.]} \quad 17.200(b)$$

$$F_y = (p_2A_2 + \dot{m}v_2)\ \sin\theta \qquad \text{[SI]} \quad 17.201(a)$$

$$F_y = \left(p_2A_2 + \frac{\dot{m}v_2}{g_c}\right)\ \sin\theta \qquad \text{[U.S.]} \quad 17.201(b)$$



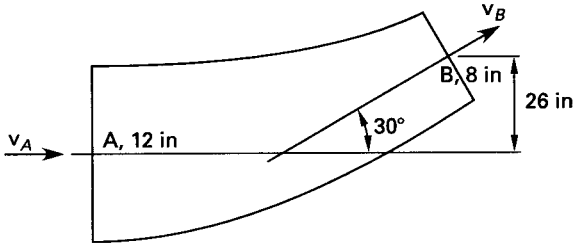


Figure 17.40 *Pipe Bend*

Example 17.13

60°F water ($\rho = 62.4$ lbm/ft^3) at 40 psig enters a 12 in × 8 in reducing elbow at 8 ft/sec and is turned through an angle of 30°. Water leaves 26 in higher in elevation. (a) What is the resultant force exerted on the water by the elbow? (b) What other forces should be considered in the design of supports for the fitting?

Solution

(a) The velocity and pressure at point B are both needed. The velocity is easily calculated from the continuity equation.

$$A_A = \frac{\pi}{4}D_A^2 = \left(\frac{\pi}{4}\right)\left(\frac{12\text{ in}}{12\ \frac{\text{in}}{\text{ft}}}\right)^2 = 0.7854\text{ ft}^2$$

$$A_B = \left(\frac{\pi}{4}\right)\left(\tfrac{8}{12}\right)^2 = 0.3491\text{ ft}^2$$

$$v_B = \frac{v_A A_A}{A_B} = \left(8\ \frac{\text{ft}}{\text{sec}}\right)\left(\frac{0.7854\text{ ft}^2}{0.3491\text{ ft}^2}\right) = 18\text{ ft/sec}$$

$$p_A = \left(40\ \frac{\text{lbf}}{\text{in}^2}\right)\left(144\ \frac{\text{in}^2}{\text{ft}^2}\right) = 5760\text{ lbf/ft}^2$$

The Bernoulli equation is used to calculate p_B. (Notice that gage pressures are used. Absolute pressures could also be used, but the addition of p_{atm}/ρ to both sides of the Bernoulli equation would not affect p_B.)

$$\frac{5760\ \frac{\text{lbf}}{\text{ft}^2}}{62.4\ \frac{\text{lbm}}{\text{ft}^3}} + \frac{\left(8\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)} = \frac{p_B}{62.4} + \frac{(18)^2}{(2)(32.2)} + \left(\frac{26\text{ in}}{12\ \frac{\text{in}}{\text{ft}}}\right) \times \left(\frac{g}{g_c}\right)$$

$$p_B = 5373\text{ lbf/ft}^2$$

The mass flow rate is

$$\dot{m} = \dot{V}\rho = vA\rho = \left(8\ \frac{\text{ft}}{\text{sec}}\right)(0.7854\text{ ft}^2)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right) = 392.1\text{ lbm/sec}$$

From Eq. 17.200,

$$F_x = \left(5373\ \frac{\text{lbf}}{\text{ft}^2}\right)(0.3491\text{ ft}^2)(\cos 30°) - \left(5760\ \frac{\text{lbf}}{\text{ft}^2}\right)(0.7854\text{ ft}^2) + \frac{\left(392.1\ \frac{\text{lbm}}{\text{sec}}\right)\left[\left(18\ \frac{\text{ft}}{\text{sec}}\right)(\cos 30°) - 8\ \frac{\text{ft}}{\text{sec}}\right]}{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} = -2807\text{ lbf}$$

From Eq. 17.201,

$$F_y = \left[(5373)(0.3491) + \frac{(392.1)(18)}{32.2}\right](\sin 30°) = 1047\text{ lbf}$$

The resultant force on the water is

$$R = \sqrt{F_x^2 + F_y^2} = \sqrt{(-2807\text{ lbf})^2 + (1047\text{ lbf})^2} = 2996\text{ lbf}$$

(b) In addition to counteracting the resultant force, R, the support should be designed to carry the weight of the elbow and the water in it. Also, the support must carry a part of the pipe and water weight tributary to the elbow.

48. WATER HAMMER

Water hammer in a long pipe is an increase in fluid pressure caused by a sudden velocity decrease. The sudden velocity decrease will usually be caused by a valve closing. Analysis of the water hammer phenomenon can

take two approaches, depending on whether or not the pipe material is assumed to be elastic.

If the pipe material is assumed to be inelastic (i.e., rigid pipe), the time required for the water hammer shock wave to travel from the suddenly closed valve to a point of interest depends only on the velocity of sound in the fluid (a) and the distance (L) between the two points. This is also the time required to bring all of the fluid in the pipe to rest.

$$t = \frac{L}{a} \qquad 17.202$$

When the water hammer shock wave reaches the original source of water, the pressure wave will dissipate. A rarefaction wave (at the pressure of the water source) will return at velocity a to the valve. The time for the compression shock wave to travel to the source and the rarefaction wave to return to the valve is given by Eq. 17.203. This is also the length of time that the pressure is constant at the valve.

$$t = \frac{2L}{a} \qquad 17.203$$

The fluid pressure increase resulting from the shock wave is calculated by equating the kinetic energy change of the fluid with the average pressure during the compression process. The pressure increase is independent of the length of pipe. If the velocity is decreased by an amount Δv instantaneously, the increase in pressure will be

$$\Delta p = \rho a \Delta v \qquad \text{[SI]} \quad 17.204(a)$$

$$\Delta p = \frac{\rho a \Delta v}{g_c} \qquad \text{[U.S.]} \quad 17.204(b)$$

It is interesting that the pressure increase at the valve depends on Δv but not on the actual length of time it takes to close the valve, as long as the valve is closed when the wave returns to it. Therefore, there is no difference in pressure buildups at the valve for an "instantaneous closure," "rapid closure," or "sudden closure."[30] It is only necessary for the closure to occur rapidly. Because of this, some authorities recommend that the valve closure time be at least ten times the wave return duration calculated in Eq. 17.203.

Having a very long pipe is equivalent to assuming an instantaneous closure. When the pipe is long, the time for the shock wave to travel round-trip is much longer than the time to close the valve. Thus, the valve will be closed when the rarefaction wave returns to the valve.

If the pipe is short, it will be difficult to close the valve before the rarefaction wave returns to the valve. With a short pipe, the pressure buildup will be less than is predicted by Eq. 17.204. (Having a short pipe is equivalent to the case of "slow closure.") The actual pressure history is complex, and no simple method exists for calculating the pressure buildup in short pipes.

[30]The pressure elsewhere along the pipe, however, will be lower for slow closures than for instantaneous closures.

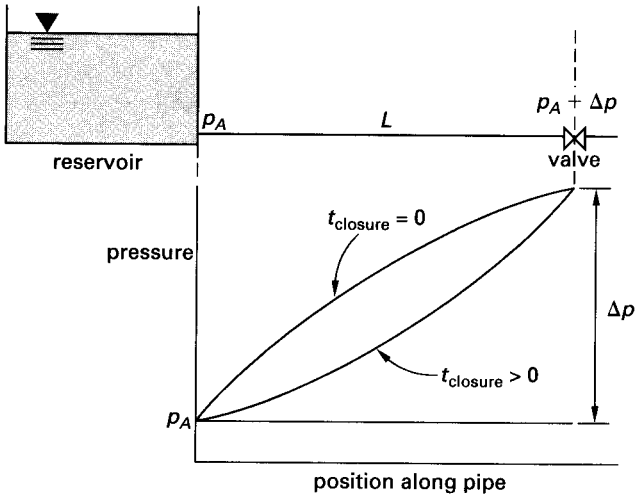

Figure 17.41 *Water Hammer*

Installing a *surge tank, accumulator, slow-closing valve,* or *pressure-relief valve* in the line will protect against water hammer damage. The surge tank (or *surge chamber*) is an open tank or reservoir. Since the water is unconfined, large pressure buildups do not occur. An accumulator is a closed tank that is partially filled with air. Since the air is much more compressible than the water, it will be compressed by the water hammer shock wave. The energy of the shock wave is dissipated when the air is compressed.

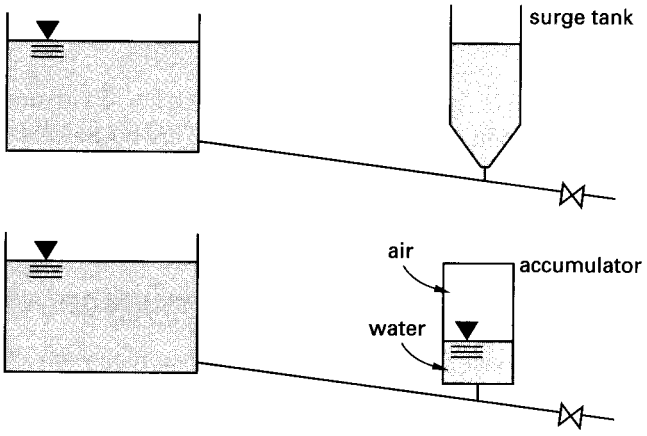

Figure 17.42 *Water Hammer Protective Devices*

If the pipe material is elastic (the typical assumption for steel and plastic), the previous analysis of water hammer effects (t and Δp) is still valid. However, the calculation of the speed of sound in water must account for the elasticity of the pipe material. This is accomplished by using Eq. 17.205 for the modulus of elasticity (bulk modulus) when calculating the speed of sound, a. (In Eq. 17.205, t is the pipe wall thickness and D is the pipe inside diameter.)

$$E = \frac{E_{\text{water}}\, t_{\text{pipe}}\, E_{\text{pipe}}}{t_{\text{pipe}}\, E_{\text{pipe}} + D_{\text{pipe}} E_{\text{water}}} \qquad 17.205$$

Equation 17.205 indicates that E (and, hence, the effect of water hammer) can be reduced by using a larger diameter pipe. The size of the valve does not affect the wave velocity.

Example 17.14

Water ($\rho = 1000$ kg/m^3, $E = 2 \times 10^9$ Pa) is flowing at 4 m/s through a long length of 4 in schedule-40 steel pipe ($D_i = 0.102$ m, $t = 0.00602$ m, $E = 2 \times 10^{11}$ Pa) when a valve suddenly closes completely. What is the theoretical increase in pressure?

Solution

From Eq. 17.205, the modulus of elasticity to be used in calculating the speed of sound is

$$E = \frac{(2 \times 10^9 \text{ Pa})(0.00602 \text{ m})(2 \times 10^{11} \text{ Pa})}{(0.00602 \text{ m})(2 \times 10^{11} \text{ Pa}) + (0.102 \text{ m})(2 \times 10^9 \text{ Pa})}$$
$$= 1.71 \times 10^9 \text{ Pa}$$

The speed of sound in the pipe is

$$a = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{1.71 \times 10^9 \text{ Pa}}{1000 \frac{\text{kg}}{\text{m}^2}}}$$
$$= 1308 \text{ m/s}$$

From Eq. 17.204, the pressure increase is

$$\Delta p = \rho a \Delta \text{v} = \left(1000 \frac{\text{kg}}{\text{m}^3}\right)\left(1308 \frac{\text{m}}{\text{s}}\right)\left(4 \frac{\text{m}}{\text{s}}\right)$$
$$= 5.23 \times 10^6 \text{ Pa}$$

49. LIFT

Lift is an upward force that is exerted on an object (flat plate, airfoil, rotating cylinder, etc.) as the object passes through a fluid. Lift combines with drag to form the resultant force on the object, as shown in Fig. 17.43.

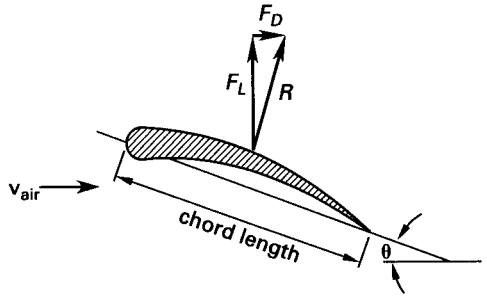

Figure 17.43 *Lift and Drag on an Airfoil*

The generation of lift from air flowing over an airfoil is predicted by Bernoulli's equation. Air molecules must travel a longer distance over the top surface of the airfoil than over the lower surface, and, therefore, they travel faster over the top surface. Since the total energy of the air is constant, the increase in kinetic energy comes at the expense of pressure energy. The static pressure on the top of the airfoil is reduced, and a net upward force is produced.

Within practical limits, the lift produced can be increased at lower speeds by increasing the curvature of the wing. This increased curvature is achieved by the use of *flaps*. When a plane is traveling slowly (e.g., during take-off or landing), its flaps are extended to create the lift needed.

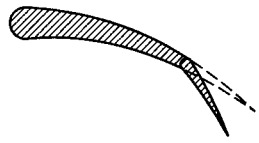

Figure 17.44 *Use of Flaps in an Airfoil*

The lift produced can be calculated from Eq. 17.206, whose use is not limited to airfoils.

$$F_L = \frac{C_L A \rho \text{v}^2}{2} \qquad \text{[SI]} \quad 17.206(a)$$

$$F_L = \frac{C_L A \rho \text{v}^2}{2g_c} \qquad \text{[U.S.]} \quad 17.206(b)$$

The dimensions of an airfoil or wing are frequently given in terms of chord length and aspect ratio. The *chord length* is the front-to-back dimension of the airfoil. The *aspect ratio* is the ratio of the *span* (wing length) to chord length. The area, A, in Eq. 17.206 is the airfoil's area projected onto the plane of the chord. Thus, for a rectangular airfoil, A = chord × span.

The dimensionless *coefficient of lift*, C_L, is used to measure the effectiveness of the airfoil. The coefficient of lift depends on the shape of the airfoil and the Reynolds number. No simple relationship can be given for calculating the coefficient of lift for airfoils, but the theoretical coefficient of lift for a thin plate in two-dimensional flow at a low angle of attack, θ, is given by Eq. 17.207. Actual airfoils are able to achieve only 80 to 90% of this theoretical value.

$$C_L = 2\pi \sin\theta \qquad 17.207$$

The coefficient of lift for an airfoil cannot be increased without limit merely by increasing θ. Eventually, the *stall angle* is reached, at which point the coefficient of lift decreases dramatically.

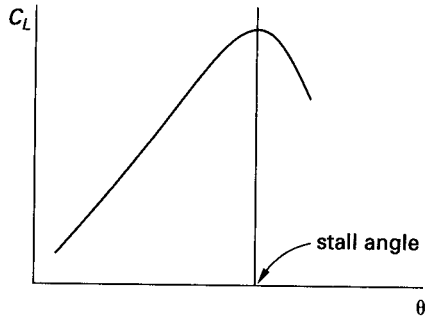

Figure 17.45 *Typical Plot of Lift Coefficient*

50. CIRCULATION

A theoretical concept for calculating the lift generated by an object (an airfoil, propeller, turbine blade, etc.) is *circulation.* Circulation, Γ, is defined by Eq. 17.208.[31] Its units are length^2/time.

$$\Gamma = \oint \mathrm{v}\ \cos\theta\ dl \qquad 17.208$$

Figure 17.46 illustrates an arbitrary closed curve drawn around a point (or body) in steady flow. The tangential components of velocity, v, at all points around the curve are v $\cos\theta$. It is a fundamental theorem that circulation has the same value for every closed curve that can be drawn around a body.

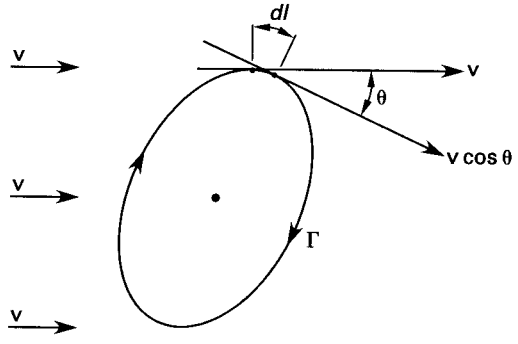

Figure 17.46 *Circulation Around a Point*

Lift on a body traveling with relative velocity v through a fluid of density ρ can be calculated from the circulation by using Eq. 17.209.[32]

$$F_L = \rho\ \mathrm{v}\Gamma \times \text{ chord length} \qquad 17.209$$

There is no actual circulation of air "around" an airfoil, but this mathematical concept can be used, nevertheless. However, since the flow of air "around" an airfoil is not symmetrical in path or velocity, experimental determination of C_L is favored over theoretical calculations of circulation.

51. LIFT FROM ROTATING CYLINDERS

When a cylinder is placed transversely to an airflow traveling at velocity v_∞, the velocity at a point on the surface of the cylinder is $2\mathrm{v}_\infty \sin\theta$. Since the flow is symmetrical, however, no lift is produced.

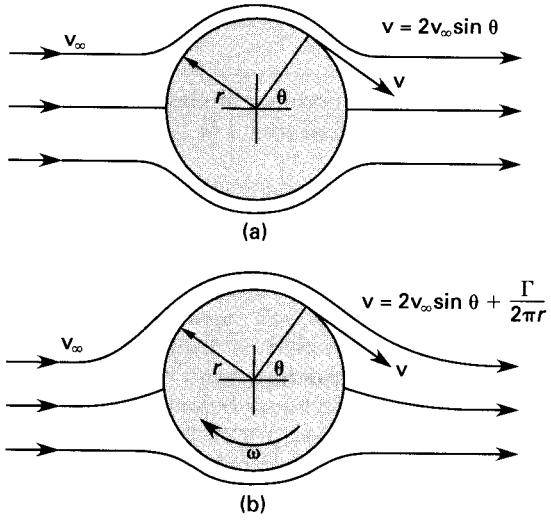

Figure 17.47 *Flow Over a Cylinder*

If the cylinder with radius r is rotating at ω rad/sec while it moves with a relative velocity v_∞ through the air, the *Kutta-Joukowsky result* (theorem) can be used to calculate the lift per unit length of cylinder.[33] This is known as the *Magnus effect.*

$$F_L \text{ (per unit length)} = \rho \mathrm{v}_\infty \Gamma \quad \text{[SI]} \qquad 17.210(a)$$

$$F_L = \frac{\rho \mathrm{v}_\infty \Gamma}{g_c} \quad \text{[U.S.]} \qquad 17.210(b)$$

$$\Gamma = 2\pi r^2 \omega \qquad 17.211$$

Equation 17.210 assumes that there is no slip (i.e., that the air drawn around the cylinder by rotation moves at ω), and in that ideal case, the maximum coefficient of lift is 4π. Practical rotating devices, however, seldom achieve a coefficient of lift in excess of 9 or 10, and even then, the power expenditure is excessive.

52. DRAG

Drag is a frictional force that acts parallel but opposite to the direction of motion. It combines with the lift (acting perpendicular to the direction of motion) to

[31] Equation 17.208 is analogous to the calculation of work being done by a constant force moving around a curve. If the force makes an angle of θ with the direction of motion, the work done as the force moves a distance dl around a curve is $W = \oint F \cos\theta\ dl$. In calculating circulation, velocity takes the place of force.

[32] U is the traditional symbol of velocity in circulation studies.

[33] A similar analysis can be used to explain why a pitched baseball curves. The rotation of the ball produces a force that changes the path of the ball as it travels.

produce a resultant force on the object. The total drag force is made up of *skin friction* and *pressure drag* (also known as *form drag*). These components, in turn, can be subdivided and categorized into *wake drag, induced drag*, and *profile drag.*

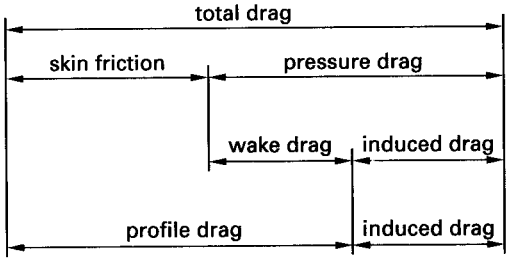

Figure 17.48 *Components of Total Drag*

Most aeronautical engineering books contain descriptions of these drag terms. However, the difference between the situations where either skin friction drag or pressure drag predominates is illustrated in Fig. 17.49.

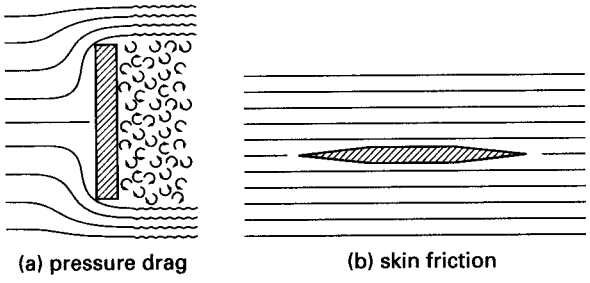

Figure 17.49 *Extreme Cases of Pressure Drag and Skin Friction*

Total drag is most easily calculated from the dimensionless *drag coefficient*, C_D. It can be shown by dimensional analysis that the drag coefficient depends only on the Reynolds number.

$$F_D = \frac{C_D A \rho v^2}{2} \qquad \text{[SI]} \quad 17.212(a)$$

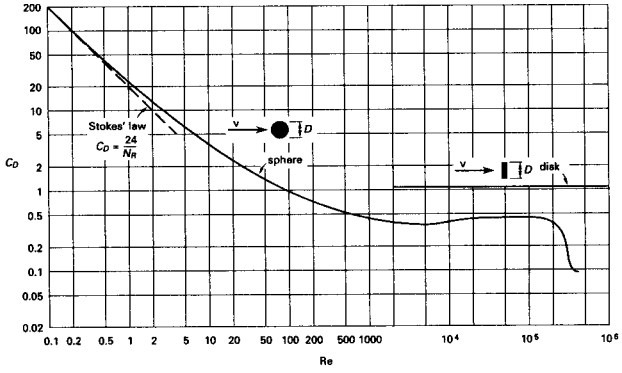
$$F_D = \frac{C_D A \rho v^2}{2g_c} \qquad \text{[U.S.]} \quad 17.212(b)$$

In most cases, the area, A, in Eq. 17.212 is the projected area (i.e., the *frontal area*) normal to the stream. This is appropriate for spheres, cylinders, and automobiles. In a few cases (e.g., for airfoils and flat plates), the area is a projection of the object onto a plane parallel to the stream.

Typical drag coefficients for production cars vary from approximately 0.35 to approximately 0.55, with most modern cars being nearer the lower end. By comparison, other low-speed drag coefficients are approximately 0.05 (aircraft wing), 0.10 (sphere in turbulent flow), and 1.2 (flat plate).

Aero horsepower is a term used by automobile manufacturers to designate the power required to move a car horizontally at 50 mi/hr (80.5 km/h) against the drag force. Aero horsepower varies from approximately 7 hp (5.2 kW) for a streamlined subcompact car to approximately 100 hp (75 kW) for a box-shaped truck.

53. DRAG ON SPHERES AND DISKS



The drag coefficient varies linearly with the Reynolds number for laminar flow around a sphere or disk. In this region, the drag is almost entirely due to skin friction. For Reynolds numbers below approximately 0.4, experiments have shown that the drag coefficient can be calculated from Eq. 17.211.[34] In calculating the Reynolds number, the sphere or disk diameter should be used as the characteristic dimension.

$$C_D = \frac{24}{\text{Re}} \qquad 17.213$$

Substituting this value of C_D into Eq. 17.212 results in *Stokes' law*, which is applicable to slow motion (ascent or descent) of spherical particles and bubbles traveling at velocity v through a fluid. Stokes' law is based on the assumptions that (a) flow is laminar, (b) Newton's law of viscosity is valid, and (c) all higher-order velocity terms (v^2, etc.) are negligible.

$$F_D = 3\pi\mu v D \qquad 17.214$$

The drag coefficients for disks and spheres operating outside the region covered by Stokes' law have been determined experimentally. In the turbulent region, pressure drag is predominant. Figure 17.50 can be used to obtain approximate values for C_D.

Fluid Mechanics, 5th Edition by Binder, © 1973. Reprinted by permission of Prentice-Hall, Inc., Upper Saddle River, NJ.

Figure 17.50 *Drag Coefficients for Spheres and Circular Flat Disks*

Figure 17.50 shows that there is a dramatic drop in the drag coefficient around Re = 10^5. The explanation

[34]Some sources report that the region in which Stokes' law applies extends to Re = 1.0.

for this is that the point of separation of the boundary layer shifts, decreasing the width of the wake. Since the drag force is primarily pressure drag at higher Reynolds numbers, a reduction in the wake reduces the pressure drag. Thus, anything that can be done to a sphere (scuffing or wetting a baseball, dimpling a golf ball, etc.) to induce a smaller wake will reduce the drag. There can be no shift in the boundary layer separation point for a thin disk, since the disk has no depth in the direction of flow. Therefore, the drag coefficient remains the same at all turbulent Reynolds numbers.

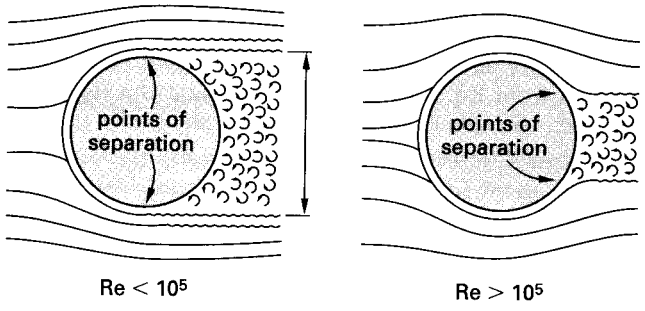


Figure 17.51 *Turbulent Flow Around a Sphere at Various Reynolds Numbers*

54. TERMINAL VELOCITY

The velocity of an object falling through a fluid will continue to increase until the drag force equals the net downward force (i.e., the weight less the buoyant force). The maximum velocity attained is known as the *terminal velocity.* At terminal velocity,

$$F_D = mg - F_b \qquad \text{[SI]} \quad 17.215(a)$$

$$F_D = m \times \left(\frac{g}{g_c}\right) - F_b \qquad \text{[U.S.]} \quad 17.215(b)$$

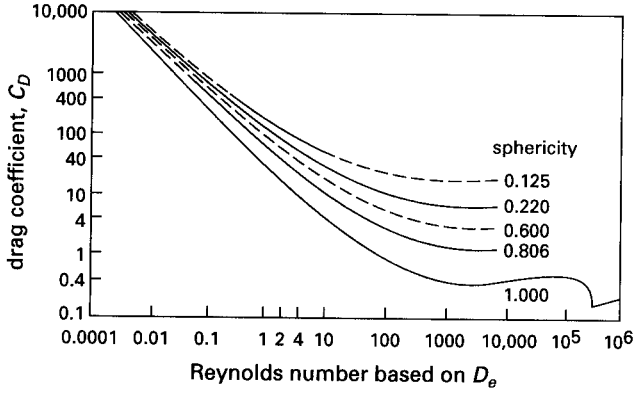
If the drag coefficient is known, the terminal velocity can be calculated from Eq. 17.216. For small, heavy objects falling in air, the buoyant force can be neglected.

$$\mathrm{v} = \sqrt{\frac{2(mg - F_b)}{C_D A \rho_{\text{fluid}}}} = \sqrt{\frac{2Vg(\rho_{\text{object}} - \rho_{\text{fluid}})}{C_D A\ \rho_{\text{fluid}}}} \qquad 17.216$$

For a sphere of diameter D, the terminal velocity is

$$\mathrm{v} = \sqrt{\frac{4Dg(\rho_{\text{sphere}} - \rho_{\text{fluid}})}{3C_D \rho_{\text{fluid}}}} \qquad 17.217$$

If the spherical particle is very small, Stokes' law may apply. In that case, the terminal velocity can be calculated from Eq. 17.218.



$$\mathrm{v} = \frac{D^2 g(\rho_{\text{sphere}} - \rho_{\text{fluid}})}{18\ \mu} \qquad \text{[SI]} \quad 17.218(a)$$

$$\mathrm{v} = \frac{D^2(\rho_{\text{sphere}} - \rho_{\text{fluid}})}{18\ \mu} \times \left(\frac{g}{g_c}\right) \qquad \text{[U.S.]} \quad 17.218(b)$$

55. NONSPHERICAL PARTICLES

Only the most simple bodies can be modeled as spheres. One method of overcoming the complexity of dealing with the flow of real particles is to correlate performance with *sphericity.* For a particle and a sphere with the same volume, the sphericity is defined by Eq. 17.219. Sphericity will always be less than or equal to 1.0.

$$\text{sphericity} = \frac{A_{\text{sphere}}}{A_{\text{particle}}} \qquad 17.219$$

Reprinted with permission from George Granger Brown, et. al., *Unit Operations,* © 1950, by John Wiley & Sons, Inc.

Figure 17.52 *Drag Coefficients for Nonspherical Particles*

Another parameter that can be used to describe the deviation from ideal spherical behavior is the ratio of equivalent to average diameters, D_e/D_{ave}. The *average diameter* can be determined by screening a sample of the particles and evaluating the size distribution. The *equivalent diameter* is the diameter of a sphere having the same volume as the particle.

56. FLOW AROUND A CYLINDER

The characteristic drag coefficient plot for cylinders placed normal to the fluid flow is similar to the plot for spheres. The plot shown in Fig. 17.53 is for infinitely long cylinders, since there is additional wake drag at the cylinder ends. In calculating the Reynolds number, the cylinder diameter should be used as the characteristic dimension.

Example 17.15

A 50 ft (15 m) high flagpole is constructed of a uniformly smooth cylinder 10 in (25 cm) in diameter. The surrounding air is at 40°F (0°C) and 14.6 psia (100 kPa). What is the total drag force on the flagpole in a 30 mi/hr (50 km/h) gust? (Neglect variations in the wind speed with height above the ground.)

SI Solution

At 0°C, the absolute viscosity of air is

$$\mu_{p,0^\circ C} = 1.709 \times 10^{-5} \text{ Pa·s} \quad \text{[App. 14.E]}$$

The density of the air is

$$\rho_p = \frac{p}{RT} = \frac{(100 \text{ kPa})\left(1000 \frac{\text{Pa}}{\text{kPa}}\right)}{\left(287 \frac{\text{J}}{\text{kg·K}}\right)(0^\circ C + 273)}$$

$$= 1.276 \text{ kg/m}^3$$

The kinematic viscosity is

$$\nu_p = \frac{\mu}{\rho} = \frac{1.709 \times 10^{-5} \text{ Pa·s}}{1.276 \frac{\text{kg}}{\text{m}^3}}$$

$$= 1.339 \times 10^{-5} \text{ m}^2/\text{s}$$

The wind speed is

$$\text{v} = \frac{\left(50 \frac{\text{km}}{\text{h}}\right)\left(1000 \frac{\text{m}}{\text{km}}\right)}{3600 \frac{\text{s}}{\text{h}}} = 13.89 \text{ m/s}$$

The characteristic dimension of the flagpole is its diameter. The Reynolds number is

$$\text{Re} = \frac{L\text{v}}{\nu} = \frac{\left(\frac{25 \text{ cm}}{100 \frac{\text{cm}}{\text{m}}}\right)\left(13.89 \frac{\text{m}}{\text{s}}\right)}{1.339 \times 10^{-5} \frac{\text{m}^2}{\text{s}}}$$

$$= 2.59 \times 10^5$$

From Fig. 17.53 for this Reynolds number, the drag coefficient is approximately 1.2.

The frontal area of the flagpole is

$$A = DL = \frac{(25 \text{ cm})(15 \text{ m})}{100 \frac{\text{cm}}{\text{m}}}$$

$$= 3.75 \text{ m}^2$$

From Eq. 17.212(a), the drag on the flagpole is

$$F_D = \frac{C_D A \rho \text{v}^2}{2}$$

$$= \frac{(1.2)(3.75 \text{ m}^2)\left(1.276 \frac{\text{kg}}{\text{m}^3}\right)\left(13.89 \frac{\text{m}}{\text{s}}\right)^2}{2}$$

$$= 554 \text{ N}$$

Customary U.S. Solution

At 40°F, the absolute viscosity of air is

$$\mu_{p,40^\circ F} = 3.62 \times 10^{-7} \text{ lbf-sec/ft}^2 \quad \text{[App. 14.D]}$$

The density of the air is

$$\rho_p = \frac{p}{RT} = \frac{\left(14.6 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(53.3 \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(40^\circ F + 460)}$$

$$= 0.07889 \text{ lbm/ft}^3$$

The kinematic viscosity is

$$\nu_p = \frac{\mu g_c}{\rho} = \frac{\left(3.62 \times 10^{-7} \frac{\text{lbf-sec}}{\text{ft}^2}\right)\left(32.2 \frac{\text{ft-lbm}}{\text{lbf-sec}^2}\right)}{0.07889 \frac{\text{lbm}}{\text{ft}^3}}$$

$$= 1.478 \times 10^{-4} \text{ ft}^2/\text{sec}$$

The wind speed is

$$v = \frac{\left(30\ \frac{\text{mi}}{\text{hr}}\right)\left(5280\ \frac{\text{ft}}{\text{mi}}\right)}{3600\ \frac{\text{sec}}{\text{hr}}} = 44\ \text{ft/sec}$$

The characteristic dimension of the flagpole is its diameter. The Reynolds number is

$$\text{Re} = \frac{Lv}{\nu} = \frac{\left(\frac{10\ \text{in}}{12\ \frac{\text{in}}{\text{ft}}}\right)\left(44\ \frac{\text{ft}}{\text{sec}}\right)}{1.478 \times 10^{-4}\ \frac{\text{ft}^2}{\text{sec}}}$$
$$= 2.48 \times 10^5$$

From Fig. 17.53 for this Reynolds number, the drag coefficient is approximately 1.2.

The frontal area of the flagpole is

$$A = DL = \frac{(10\ \text{in})(50\ \text{ft})}{12\ \frac{\text{in}}{\text{ft}}} = 41.67\ \text{ft}^2$$

From Eq. 17.212(b), the drag on the flagpole is

$$F_D = \frac{C_D A \rho v^2}{2g_c}$$
$$= \frac{(1.2)(41.67\ \text{ft}^2)\left(0.07889\ \frac{\text{lbm}}{\text{ft}^3}\right)\left(44\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{ft-lbm}}{\text{lbf-sec}^2}\right)}$$
$$= 118.6\ \text{lbf}$$

57. FLOW OVER A PARALLEL FLAT PLATE

The drag experienced by a flat plate oriented parallel to the direction of flow is almost totally skin friction drag. Prandtl's *boundary layer theory* can be used to evaluate the frictional effects. Such an analysis shows that the shape of the boundary layer is a function of the Reynolds number. The characteristic dimension used in calculating the Reynolds number is the chord length, L (i.e., the dimension of the plate parallel to the flow).

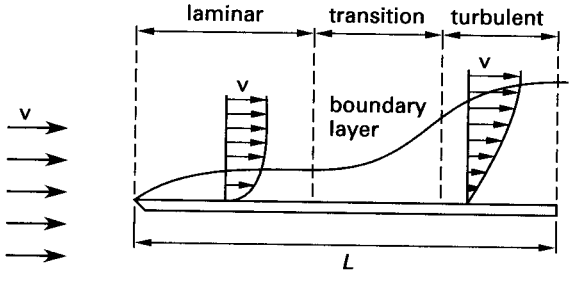

Figure 17.54 *Flow Over a Parallel Flat Plate (one side)*

When skin friction predominates, it is common to use the symbol C_f (i.e., the *skin friction coefficient*) for the drag coefficient. For laminar flow over a smooth, flat plate, the drag coefficient based on the boundary layer theory is given by Eq. 17.220, which is known as the *Blasius solution.*[35] The critical Reynolds number for laminar flow is often reported to be 530,000. However, the transition region between laminar flow and turbulent flow actually occupies the Reynolds number range of 100,000 to 1,000,000.

$$C_f = \frac{1.328}{\sqrt{\text{Re}}} \qquad 17.220$$

Prandtl reported that the skin friction coefficient for turbulent flow is

$$C_f = \frac{0.455}{(\log\ \text{Re})^{2.58}} \qquad 17.221$$

The drag force is calculated from Eq. 17.222. The factor 2 is used because there is friction on two sides of the flat plate.

$$F_D = 2\left(\frac{C_f A \rho v^2}{2}\right) = C_f A \rho v^2 \quad \text{[SI]} \qquad 17.222(a)$$

$$F_D = 2\left(\frac{C_f A \rho v^2}{2g_c}\right) = \frac{C_f A \rho v^2}{g_c} \quad \text{[U.S.]} \qquad 17.222(b)$$

58. SIMILARITY

Similarity considerations between a *model* (subscript m) and a full-sized object (subscript p, for *prototype*) imply that the model can be used to predict the performance of the prototype. Such a model is said to be *mechanically similar* to the prototype.

Complete *mechanical similarity* requires both geometric and dynamic similarity.[36] *Geometric similarity* means that the model is true to scale in length, area, and volume. The *model scale (length ratio)* is defined as

$$L_r = \frac{\text{size of model}}{\text{size of prototype}} \qquad 17.223$$

The area and volume ratios are based on the model scale.

$$\frac{A_m}{A_p} = (L_r)^2 \qquad 17.224$$

$$\frac{V_m}{V_p} = (L_r)^3 \qquad 17.225$$

[35] Other correlations substitute the coefficient 1.44, the original value calculated by Prandtl, for 1.328 in Eq. 17.220. The Blasius solution is considered to be more accurate.

[36] Complete mechanical similarity also requires kinematic and thermal similarity, which are not discussed in this book.

Dynamic similarity means that the ratios of all types of forces are equal for the model and the prototype. These forces result from inertia, gravity, viscosity, elasticity (i.e., fluid compressibility), surface tension, and pressure.

The number of possible ratios of forces is large. For example, the ratios of viscosity/inertia, inertia/gravity, and inertia/surface tension are only three of the ratios of forces that must match for every corresponding point on the model and prototype. Fortunately, some force ratios can be neglected because the forces are negligible or are self-canceling.

In some cases, the geometric scale may be deliberately distorted. For example, with scale models of harbors and rivers, the water depth might be only a fraction of an inch if the scale is followed loyally. Not only will the surface tension be excessive, but the shifting of the harbor or river bed may not be properly observed. Therefore, the vertical scale is chosen to be different from the horizontal scale. Such models are known as *distorted models*. Experience is needed to interpret observations made of distorted models.

The following sections deal with the most common similarity problems, but not all. For example, similarity of steady laminar flow in a horizontal pipe requires the Stokes number, similarity of high-speed (near-sonic) aircraft requires the Mach number, and similarity of capillary rise in a tube requires the *Eötvös number* ($g\rho L^2/\sigma$).

59. VISCOUS AND INERTIAL FORCES DOMINATE

Consider the testing of a completely submerged object, such as the items listed in Table 17.9. Surface tension will be negligible. The fluid can be assumed to be incompressible for low velocity. Gravity does not change the path of the fluid particles significantly during the passage of the object.

Table 17.9 *Cases with Reynolds Number Similarity*

aircraft (subsonic)
airfoils (subsonic)
closed-pipe flow (turbulent)
drainage through tank orifices
fans
flow meters
open channel flow (without wave action)
pumps
submarines
torpedoes
turbines

Only inertial, viscous, and pressure forces are significant. Because they are the only forces that are acting, these three forces are in equilibrium. Since they are in equilibrium, knowing any two forces will define the third force. This third force is dependent and can be omitted from the similarity analysis. For submerged objects, pressure is traditionally chosen as the dependent force.

The dimensionless ratio of the inertial forces to the viscous forces is the Reynolds number. Equating the model's and prototype's Reynolds numbers will ensure similarity.[37]

$$\mathrm{Re}_m = \mathrm{Re}_p \qquad 17.226$$

$$\frac{L_m \mathrm{v}_m}{\nu_m} = \frac{L_p \mathrm{v}_p}{\nu_p} \qquad 17.227$$

If the model is tested in the same fluid and at the same temperature in which the prototype is expected to operate, setting the Reynolds numbers equal is equivalent to setting $L_m \mathrm{v}_m = L_p \mathrm{v}_p$.

Example 17.16

A $^1/_{30\text{th}}$ size scale model of a helicopter fuselage is tested in a wind tunnel at 120 mi/hr (190 km/h). The conditions in the wind tunnel are 50 psia and 100°F (350 kPa and 50°C). What is the corresponding speed of a prototype traveling in 14.0 psia and 40°F still air (100 kPa, 0°C)?

SI Solution

From App. 14.E,

$$\mu_{p,0^\circ\mathrm{C}} = 1.709 \times 10^{-5}\ \mathrm{Pa \cdot s}$$

$$\mu_{m,50^\circ\mathrm{C}} = 1.951 \times 10^{-5}\ \mathrm{Pa \cdot s}$$

The densities of air at the two conditions are

$$\rho_p = \frac{p}{RT} = \frac{(100\ \mathrm{kPa})\left(1000\ \frac{\mathrm{Pa}}{\mathrm{kPa}}\right)}{\left(287\ \frac{\mathrm{J}}{\mathrm{kg \cdot K}}\right)(0^\circ\mathrm{C} + 273)} = 1.276\ \mathrm{kg/m^3}$$

$$\rho_m = \frac{p}{RT} = \frac{(350\ \mathrm{kPa})\left(1000\ \frac{\mathrm{Pa}}{\mathrm{kPa}}\right)}{\left(287\ \frac{\mathrm{J}}{\mathrm{kg \cdot K}}\right)(50^\circ\mathrm{C} + 273)} = 3.776\ \mathrm{kg/m^3}$$

[37] An implied assumption is that the drag coefficients are the same for the model and the prototype. In the case of pipe flow, it is assumed that flow will be in the turbulent region with the same relative roughness.

The kinematic viscosities are

$$\nu_p = \frac{\mu}{\rho} = \frac{1.709 \times 10^{-5} \text{ Pa·s}}{1.276 \frac{\text{kg}}{\text{m}^3}} = 1.339 \times 10^{-5} \text{ m}^2/\text{s}$$

$$\nu_m = \frac{\mu}{\rho} = \frac{1.951 \times 10^{-5} \text{ Pa·s}}{3.776 \frac{\text{kg}}{\text{m}^3}} = 5.167 \times 10^{-6} \text{ m}^2/\text{s}$$

From Eq. 17.227,

$$\text{v}_p = \text{v}_m \left(\frac{L_m}{L_p}\right)\left(\frac{\nu_p}{\nu_m}\right) = \frac{\left(190 \frac{\text{km}}{\text{h}}\right)\left(\frac{1}{30}\right)\left(1.339 \times 10^{-5} \frac{\text{m}^2}{\text{s}}\right)}{5.167 \times 10^{-6} \frac{\text{m}^2}{\text{s}}} = 16.4 \text{ km/h}$$

Customary U.S. Solution

Since surface tension and gravitational forces on the air particles are insignificant and since the flow velocities are low, viscous and inertial forces dominate. The Reynolds numbers of the model and prototype are equated.

The kinematic viscosity of air must be evaluated at the respective temperatures and pressures. As kinematic viscosity tables for air are not readily available, the viscosity must be calculated. Although kinematic viscosity depends on the temperature and pressure, absolute viscosity is essentially independent of pressure. From App. 14.D,

$$\mu_{p,40°\text{F}} = 3.62 \times 10^{-7} \text{ lbf-sec/ft}^2$$

$$\mu_{m,100°\text{F}} = 3.96 \times 10^{-7} \text{ lbf-sec/ft}^2$$

The densities of air at the two conditions are

$$\rho_p = \frac{p}{RT} = \frac{\left(14.0 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(53.3 \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(40°\text{F} + 460)} = 0.0756 \text{ lbm/ft}^3$$

$$\rho_m = \frac{p}{RT} = \frac{\left(50.0 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{\left(53.3 \frac{\text{ft-lbf}}{\text{lbm-°R}}\right)(100°\text{F} + 460)} = 0.2412 \text{ lbm/ft}^3$$

The kinematic viscosities are

$$\nu_p = \frac{\mu g_c}{\rho} = \frac{\left(3.62 \times 10^{-7} \frac{\text{lbf-sec}}{\text{ft}^2}\right) g_c}{0.0756 \frac{\text{lbm}}{\text{ft}^3}} = 4.79 \times 10^{-6} \times g_c \text{ ft}^2/\text{sec}$$

$$\nu_m = \frac{\mu g_c}{\rho} = \frac{\left(3.96 \times 10^{-7} \frac{\text{lbf-sec}}{\text{ft}^2}\right) g_c}{0.2412 \frac{\text{lbm}}{\text{ft}^3}} = 1.64 \times 10^{-6} \times g_c \text{ ft}^2/\text{sec}$$

From Eq. 17.227,

$$\text{v}_p = \text{v}_m \left(\frac{L_m}{L_p}\right)\left(\frac{\nu_p}{\nu_m}\right) = \frac{\left(120 \frac{\text{mi}}{\text{hr}}\right)\left(\frac{1}{30}\right)\left(4.79 \times 10^{-6} g_c \frac{\text{ft}^2}{\text{sec}}\right)}{\left(1.64 \times 10^{-6} g_c \frac{\text{ft}^2}{\text{sec}}\right)} = 11.7 \text{ mi/hr}$$

60. INERTIAL AND GRAVITATIONAL FORCES DOMINATE

Table 17.10 lists the cases when elasticity and surface tension forces can be neglected but gravitational forces cannot. Omitting these two forces from the similarity calculations leaves pressure, inertia, viscosity, and gravity forces, which are in equilibrium. Pressure is chosen as the dependent force and is omitted from the analysis.

Table 17.10 *Cases with Froude Number Similarity*

bow waves from ships
flow over spillways
flow over weirs
motion of a fluid jet
open channel flow with varying surface levels
oscillatory wave action
seaplane hulls
surface ships
surface wave action
surge and flood waves

There are only two possible combinations of the remaining three forces. The ratio of inertial to viscous forces is the Reynolds number. The ratio of the inertial forces

to the gravitational forces is the *Froude number*, Fr.[38] The Froude number is used when gravitational forces are significant, such as in wave motion produced by a ship or seaplane hull.

$$\mathrm{Fr} = \frac{\mathrm{v}^2}{Lg} \qquad 17.228$$

Thus, similarity is ensured when Eqs. 17.229 and 17.230 are satisfied.

$$\mathrm{Re}_m = \mathrm{Re}_p \qquad 17.229$$

$$\mathrm{Fr}_m = \mathrm{Fr}_p \qquad 17.230$$

As an alternative, Eqs. 17.229 and 17.230 can be solved simultaneously. This results in the following requirement for similarity, which indicates that it is necessary to test the model in a manufactured liquid with a specific viscosity.

$$\frac{\nu_m}{\nu_p} = \left(\frac{L_m}{L_p}\right)^{\frac{3}{2}} = (L_r)^{\frac{3}{2}} \qquad 17.231$$

Sometimes it is not possible to satisfy Eqs. 17.229 and 17.230. This occurs when a model fluid viscosity is called for that is not available. If only one of the equations is satisfied, the model is said to be *partially similar*. In such a case, corrections based on other factors are used.

Another problem with trying to achieve similarity in open channel flow problems is the need to scale surface drag. It can be shown that the ratio of Manning's roughness constants is given by Eq. 17.232. In some cases, it may not be possible to create a surface smooth enough to satisfy this requirement.

$$n_r = (L_r)^{\frac{1}{6}} \qquad 17.232$$

61. SURFACE TENSION FORCE DOMINATES

Table 17.11 lists some of the cases where surface tension is the predominant force. Such cases can be handled by equating the Weber numbers, We, of the model and prototype.[39] (The *Weber number* is the ratio of inertial force to surface tension.)

$$\mathrm{We} = \frac{\mathrm{v}^2 L\rho}{\sigma} \qquad 17.233$$

$$\mathrm{We}_m = \mathrm{We}_p \qquad 17.234$$

[38]There are two definitions of the Froude number. Dimensional analysis determines the Froude number as Eq. 17.228 (v^2/Lg), a form that is used in model similitude. However, in open channel flow studies performed by civil engineers, the Froude number is taken as the square root of Eq. 17.228. Whether the derived form or its square root is used can sometimes be determined from the application. If the Froude number is squared (e.g., as in $dE/dx = 1 - \mathrm{Fr}^2$), the square root form is probably needed. In similarity problems, it doesn't make any difference which definition is used.

[39]There are two definitions of the Weber number. The alternate definition is the square root of Eq. 17.231. In similarity problems, it does not make any difference which definition of the Weber number is used.

Table 17.11 *Cases with Weber Number Similarity*

air entrainment
bubbles
droplets
waves

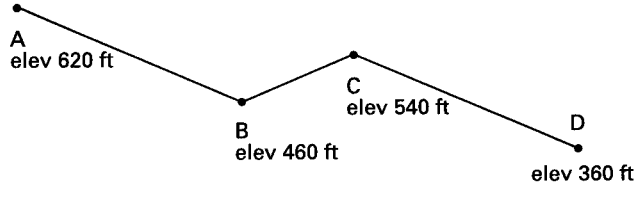
PRACTICE PROBLEMS

(Use $g = 32.2$ ft/sec^2 (9.81 m/s^2) and 60°F (16°C) water unless told to do otherwise.)

Conservation of Energy

1. 5.0 ft^3/sec (130 L/s) of water flows through a pipe that changes gradually in diameter from 6 in (154 mm) at point A to 18 in (429 mm) at point B. Point B is 15 ft (4.6 m) higher than point A. The respective pressures at points A and B are 10 psia (70 kPa) and 7 psia (48.3 kPa). All minor losses are insignificant. What are the direction of flow and velocity at point A?

(A) 3.2 ft/sec (1 m/s); from A to B
(B) 25 ft/sec (7.0 m/s); from A to B
(C) 3.2 ft/sec (1 m/s); from B to A
(D) 25 ft/sec (7.5 m/s); from B to A



The answer is (B).

2. Points A and B are separated by 3000 ft of new 6 in schedule-40 steel pipe. 750 gal/min of 60°F water flow from point A to point B. Point B is 60 ft above point A. What must be the pressure at point A if the pressure at B must be 50 psig?

(A) 87 psig
(B) 103 psig
(C) 125 psig
(D) 167 psig

The answer is (C).

3. *(Time limit: one hour)* A pipe network connects junctions A, B, C, and D as shown. All pipe sections have a C-value of 150. Water can be added and removed at any of the junctions to achieve the flows listed. Water flows from point A to point D. No flows are backward. The minimum allowable pressure anywhere in the system is 20 psi. All minor losses are insignificant. For simplification, use the nominal pipe sizes.

pipe section	length	diameter (in)	flow
A to B	20,000 ft	6	120 gal/min
B to C	10,000 ft	6	160 gal/min
C to D	30,000 ft	4	120 gal/min

(a) What is the pressure at point A?

(A) 14 psig
(B) 23 psig
(C) 31 psig
(D) 47 psig

The answer is (C).

(b) What is the elevation of the hydraulic grade line at point A referenced to point D?

(A) 330 ft
(B) 470 ft
(C) 610 ft
(D) 750 ft

The answer is (A).

Friction Loss

4. 1.5 ft^3/sec (40 L/s) of 70°F (20°C) water flows through 1200 ft (355 m) of 6 in (nominal) diameter new schedule-40 pipe. What is the friction loss?

(A) 4 ft (1.2 m)
(B) 18 ft (5.2 m)
(C) 36 ft (9.5 m)
(D) 70 ft (2.1 m)

The answer is (C).

5. 500 gal/min (30 L/s) of 100°F (40°C) water flows through 300 ft (90 m) of 6 in schedule-40 pipe. The pipe contains two 6 in flanged steel elbows, two full-open gate valves, a full-open 90° angle valve, and a backflow limiter. The discharge is located 20 ft (6 m) higher than the entrance. What is the pressure difference between the two ends of the pipe?

(A) 12 psi (78 kPa)
(B) 21 psi (140 kPa)
(C) 45 psi (310 kPa)
(D) 87 psi (600 kPa)

The answer is (A).

6. 70°F (20°C) air is flowing at 60 ft/sec (18 m/s) through 300 ft (90 m) of 6 in schedule-40 pipe. The pipe contains two 6 in flanged steel elbows, two full-open gate valves, a full-open 90° angle valve, and a backflow limiter. The discharge is located 20 ft (6 m) higher than the entrance. What is the pressure difference between the two ends of the pipe?

(A) 0.26 psi (1.8 kPa)
(B) 0.49 psi (3.2 kPa)
(C) 1.5 psi (10 kPa)
(D) 13 psi (90 kPa)

The answer is (B).

Reservoirs

7. Three reservoirs (A, B, and C) are interconnected with a common junction at elevation 25 ft above an arbitrary reference point. The water levels for reservoirs A, B, and C are at elevations of 50, 40, and 22 ft, respectively. The pipe from reservoir A to the junction is 800 ft of 3 in (nominal) steel pipe. The pipe from reservoir B to the junction is 500 ft of 10 in (nominal) steel pipe. The pipe from reservoir C to the junction is 1000 ft of 4 in (nominal) steel pipe. All pipes are schedule 40 with a friction factor of 0.02. All minor losses and velocity heads can be neglected. What are the direction of flow and pressure at point D?

(A) out of reservoir B; 500 psf
(B) out of reservoir B; 930 psf
(C) into reservoir B; 1100 psf
(D) into reservoir B; 1260 psf

The answer is (B).

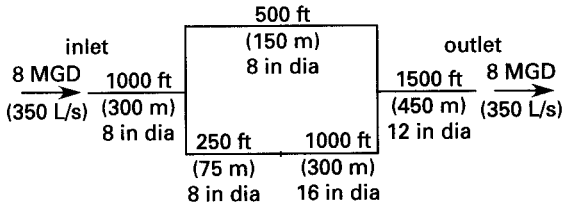
Water Hammer

8. (*Time limit: one hour*) A cast-iron pipe has an inside diameter of 24 in (600 mm) and a wall thickness of 0.75 in (20 mm). The pipe's modulus of elasticity is 20×10^6 psi (140 GPa). The pipeline is 500 ft (150 m) long. 70°F (20°C) water is flowing at 6 ft/sec (2 m/s).

(a) If a valve is closed instantaneously, what will be the maximum pressure experienced in the pipe?

(A) 48 psi (330 kPa)
(B) 140 psi (970 kPa)
(C) 320 psi (2.5 MPa)
(D) 470 psi (3.2 MPa)

The answer is (C).



(b) If the pipe is 500 ft (150 m) long, over what length of time must the valve be closed to create a pressure equivalent to instantaneous closure?

(A) 0.25 sec
(B) 0.68 sec
(C) 1.6 sec
(D) 2.1 sec

The answer is (A).

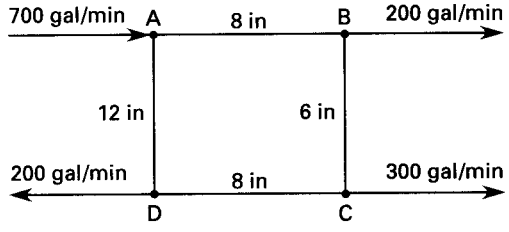
Parallel Pipe Systems

9. 8 MGD (millions of gallons per day) (350 L/s) of 70°F (20°C) water flows into the new schedule-40 steel pipe network shown. Minor losses are insignificant.

(a) What quantity of water is flowing in the upper branch?

(A) 1.2 ft^3/sec (0.034 m^3/s)
(B) 2.9 ft^3/sec (0.081 m^3/s)
(C) 4.1 ft^3/sec (0.11 m^3/s)
(D) 5.3 ft^3/sec (0.15 m^3/s)

The answer is (D).



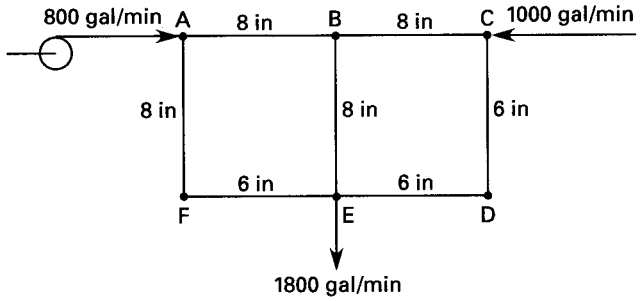
(b) What is the energy loss per unit mass between the inlet and the outlet?

(A) 120 ft-lbf/lbm (0.37 kJ/kg)
(B) 300 ft-lbf/lbm (0.90 kJ/kg)
(C) 480 ft-lbf/lbm (1.4 kJ/kg)
(D) 570 ft-lbf/lbm (1.7 kJ/kg)

The answer is (D).

Pipe Networks

10. A single-loop pipe network is shown. The distance between each junction is 1000 ft. All junctions are on the same elevation. All pipes have a C-value of 100. The volumetric flow rates are to be determined to within 2 gal/min.



What is the flow rate between junctions B and C?

(A) 36 gal/min from B to C
(B) 58 gal/min from B to C
(C) 84 gal/min from C to B
(D) 112 gal/min from C to B

The answer is (B).

11. *(Time limit: one hour)* A double-loop pipe network is shown. The distance between each junction is 1000 ft. The water temperature is 60°F. Elevations and some pressure are known for the junctions. All pipes have a C-value of 100.

point	pressure	elevation
A		200 ft
B		150 ft
C	40 psig	300 ft
D		150 ft
E		200 ft
F		150 ft

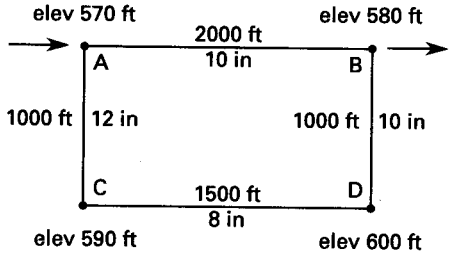
(a) What is the flow rate between junctions B and E?

(A) 540 gal/min
(B) 620 gal/min
(C) 810 gal/min
(D) 980 gal/min

The answer is (D).

(b) What is the pressure at point D?

(A) 51 psig
(B) 73 psig
(C) 96 psig
(D) 120 psig



The answer is (C).

(c) If the pump receives water at 20 psig (140 kPa), what hydraulic power is required?

(A) 14 hp
(B) 28 hp
(C) 35 hp
(D) 67 hp

The answer is (B).

12. *(Time limit: one hour)* The water distribution network shown consists of class A cast-iron pipe installed 15 years ago. 15 MGD of 50°F water enters at junction A and leaves at junction B. The minimum acceptable pressure at point D is 40 psig (280 kPa).

(a) What is the flow rate between junctions A and B?

(A) 320 gal/min
(B) 480 gal/min
(C) 590 gal/min
(D) 660 gal/min

The answer is (D).

(b) What is the pressure at point B?

(A) 32 psig
(B) 48 psig
(C) 57 psig
(D) 88 psig

The answer is (B).

Tank Discharge

13. The velocity of discharge from a fire hose is 50 ft/sec (15 m/s). The hose is oriented 45° from the horizontal. Disregarding air friction, what is the maximum range of the discharge?

(A) 45 ft (14 m)
(B) 78 ft (23 m)
(C) 91 ft (24 m)
(D) 110 ft (33 m)

The answer is (B).

14. A full cylindrical tank 40 ft (12 m) high has a constant diameter of 20 ft. The tank has a 4 in (100 mm) diameter hole in its bottom. The coefficient of discharge for the hole is 0.98. How long will it take for the water level to drop from 40 ft to 20 ft (12 m to 6 m)?

(A) 950 sec
(B) 1200 sec
(C) 1450 sec
(D) 1700 sec

The answer is (D).

Venturi Meters

15. A venturi meter with an 8 in diameter throat is installed in a 12 in diameter water line. The venturi is perfectly smooth, so that the discharge coefficient is 1.00. An attached mercury manometer registers a 4 in differential. What is the volumetric flow rate?

(A) 1.7 ft^3/sec
(B) 5.2 ft^3/sec
(C) 6.4 ft^3/sec
(D) 18 ft^3/sec

The answer is (C).

16. 60°F (15°C) benzene (specific gravity at 60°F (15°C) of 0.885) flows through an 8 in/3½ in (200 mm/90 mm) venturi meter whose coefficient of discharge is 0.99. A mercury manometer indicates a 4 in difference in the heights of the mercury columns. What is the volumetric flow rate of the benzene?

(A) 1.2 ft^3/sec (34 L/s)
(B) 9.1 ft^3/sec (250 L/s)
(C) 13 ft^3/sec (360 L/s)
(D) 27 ft^3/sec (760 L/s)

The answer is (A).

Orifice Meters

17. A sharp-edged orifice meter with a 0.2 ft diameter opening is installed in a 1.0 ft diameter pipe. 70°F water approaches the orifice at 2 ft/sec. What is the indicated pressure drop across the orifice meter?

(A) 5.9 psi
(B) 13 psi
(C) 22 psi
(D) 47 psi

The answer is (D).

18. A mercury manometer is used to measure a pressure difference across an orifice meter in a water line. The difference in mercury levels is 7 in (17.8 cm). What is the pressure differential?

(A) 1.7 psi (12 kPa)
(B) 3.2 psi (22 kPa)
(C) 7.9 psi (55 kPa)
(D) 23 psi (160 kPa)

The answer is (B).

19. A sharp-edged ISA orifice is used in a 12 in (300 mm) water line. (Figure 17.28 is applicable.) The water temperature is 70°F (20°C), and the flow rate is 10 ft^3/sec (250 L/s). The head loss across the orifice must not exceed 25 ft (7.5 m). What is the smallest orifice that can be used?

(A) 5.5 in (14 cm)
(B) 7.3 in (19 cm)
(C) 8.1 in (20 cm)
(D) 8.9 in (23 cm)

The answer is (C).

Impulse-Momentum

20. A pipe necks down from 24 in at point A to 12 in at point B. 8 ft^3/sec of 60°F water flow from point A to point B. The pressure head at point A is 20 ft. Friction is insignificant over the distance between points A and B. What are the magnitude and direction of the resultant force on the water?

(A) 2900 lbf; toward A
(B) 3500 lbf; toward A
(C) 2900 lbf; toward B
(D) 3500 lbf; toward B

The answer is (A).

21. A 2 in (50 mm) diameter horizontal water jet has an absolute velocity (with respect to a stationary point) of 40 ft/sec (12 m/s) as it strikes a curved blade. The blade is moving horizontally away with an absolute velocity of 15 ft/sec (4.5 m/s). Water is deflected 60° from the horizontal. What is the force on the blade?

(A) 18 lbf (80 N)
(B) 26 lbf (110 N)
(C) 35 lbf (160 N)
(D) 47 lbf (210 N)

The answer is (B).

Pumps

22. 2000 gal/min (125 L/s) of brine with a specific gravity of 1.2 pass through an 85% efficient pump. The centerlines of the pump's 12 in (300 mm) inlet and 8 in (200 mm) outlet are at the same elevation. The inlet suction gauge indicates 6 in (150 mm) of mercury below atmospheric. The discharge pressure gauge is located 4 ft (1.2 m) above the centerline of the pump's outlet and indicates 20 psig (138 kPa). What is the input power to the pump?

(A) 12 hp (8.9 kW)
(B) 36 hp (26 kW)
(C) 52 hp (39 kW)
(D) 87 hp (65 kW)

The answer is (B).

Turbines

23. 100 ft^3/sec (2.6 kL/s) of water pass through a horizontal turbine. The water's pressure is reduced from 30 psig (210 kPa) to 5 psi (35 kPa) vacuum. Disregarding friction, velocity, and other factors, what power is generated?

(A) 110 hp (82 kW)
(B) 380 hp (280 kW)
(C) 730 hp (540 kW)
(D) 920 hp (640 kW)

The answer is (D).

Drag

24. (*Time limit: one hour*) A car traveling through 70°F (20°C) air has the following characteristics.

frontal area	28 ft^2 (2.6 m^2)
mass	3300 lbm (1500 kg)
drag coefficient	0.42
rolling resistance	1% of weight
engine thermal efficiency	28%
fuel heating value	115,000 Btu/gal (460 MJ/L)

(a) Considering only the drag and rolling resistance, what is the fuel consumption when the car is traveling at 55 mi/hr (90 km/h)?

(A) 0.026 gal/mi (0.0043 L/km)
(B) 0.038 gal/mi (0.0065 L/km)
(C) 0.051 gal/mi (0.0097 L/km)
(D) 0.13 gal/mi (0.022 L/km)

The answer is (A).

(b) What is the percentage increase in fuel consumption at 65 mi/hr (105 km/h) compared to at 55 mi/hr (90 km/h)?

(A) 10%
(B) 20%
(C) 30%
(D) 40%

The answer is (C).

1. HYDRAULIC MACHINES

Pumps and turbines are the two basic types of hydraulic machines discussed in this chapter. Pumps convert mechanical energy into fluid energy, increasing the energy possessed by the fluid. Turbines convert fluid energy into mechanical energy, extracting energy from the fluid.

2. TYPES OF PUMPS

Pumps can be classified according to the method by which pumping energy is transferred to the fluid. This classification separates pumps into positive displacement pumps and kinetic pumps.

The most common types of *positive displacement pumps* are *reciprocating action pumps* (which use pistons, plungers, diaphragms, or bellows) and *rotary action pumps* (using vanes, screws, lobes, or progressing cavities). Such pumps discharge a fixed volume for each stroke or revolution. Energy is added intermittently to the fluid.

Kinetic pumps transform fluid kinetic energy into fluid static pressure energy. The pump imparts the kinetic energy; the pump mechanism or housing is constructed in a manner that causes the transformation. *Jet pumps* and *ejector pumps* fall into the kinetic pump category, but centrifugal pumps are the primary examples.

In the operation of a *centrifugal pump*, liquid flowing into the *suction side* (the *inlet*) is captured by the *impeller* and thrown to the outside of the pump casing. Within the casing, the velocity imparted to the fluid by the impeller is converted into pressure energy. The fluid leaves the pump through the *discharge line* (the *exit*). It is a characteristic of most centrifugal pumps that the fluid is turned approximately 90° from the original flow direction.

Table 18.1 *Generalized Characteristics of Positive Displacement and Kinetic Pumps*

characteristic	positive displacement pumps	kinetic pumps
flow rate	low	high
pressure rise per stage	high	low
constant quantity over operating range	flow rate	pressure rise
self-priming	yes	no
discharge stream	pulsing	steady
works with high viscosity fluids	yes	no

3. POSITIVE DISPLACEMENT RECIPROCATING PUMPS

Reciprocating positive displacement (PD) pumps are used with viscous fluids and slurries (up to about 8000 SSU), when the fluid is sensitive to shear, and when a high discharge pressure is required.[1] By entrapping a volume of liquid in the cylinder, reciprocating pumps provide a fixed-displacement volume per cycle. They are self-priming and inherently leak-free. Within the pressure limits of the line and pressure relief valve and the current capacity of the motor circuit, reciprocating pumps can provide an infinite discharge pressure.[2]

There are three main types of reciprocating pumps: power, direct-acting, and diaphragm. A *power pump* is a *cylinder-operated pump*. It can be single-acting or double-acting. A *single-acting pump* discharges liquid (or takes suction) only on one side of the piston, and there is only one transfer operation per crankshaft revolution. A *double-acting pump* discharges from both sides, and there are two transfers per revolution of the crank.

Traditional reciprocating pumps with pistons and rods can be either single-acting or double-acting and are suitable up to approximately 2000 psi (14 MPa). *Plunger pumps* are only single-acting and are suitable up to approximately 10,000 psi (70 MPa).

Simplex pumps have one cylinder, *duplex pumps* have two cylinders, *triplex pumps* have three cylinders, and so forth. *Direct-acting pumps* (sometimes referred to as *steam pumps*) are always double-acting. They use steam or unburned fuel gas as a motive fluid.

PD pumps are limited by both their NPSHR characteristics, acceleration head, and (for rotary pumps) slip.[3] Because the flow is unsteady, a certain amount of energy, the *acceleration head* (h_{ac}), is required to accelerate the fluid flow each stroke or cycle. If the acceleration head is too large, the NPSHR requirements may not be attainable. Acceleration head can be reduced by increasing the pipe diameter, shortening the suction piping, decreasing the pump speed, or placing a *pulsation damper* (*stabilizer*) in the suction line.[4]

Generally, friction losses with pulsating flow are calculated based on the maximum velocity attained by the fluid. Since this is difficult to determine, the maximum velocity can be approximated by multiplying the average velocity (calculated from the rated capacity) by the factors in Table 18.2.

When the suction line is "short," the acceleration head can be calculated from the length of the suction line, the average velocity in the line, and the rotational speed.[5]

[1]For SSU > 240, multiply SSU viscosity by 0.216 to get viscosity in centistokes.

[2]For this reason, a relief valve should be included in every installation of positive displacement pumps. Rotary pumps typically have integral relief valves, but external relief valves are often installed to provide easier adjusting, cleaning, and checking.

[3]Manufacturers of PD pumps prefer the term *net positive inlet pressure* (NPIP) to NPSH. NPIPA corresponds to NPSHA; NPIPR corresponds to NPSHR. Pressure and head are related by $p = \gamma h$.

[4]Pulsation dampers are not needed with rotary-action PD pumps, as the discharge is essentially constant.

[5]With a properly designed pulsation damper, the effective length of the suction line is reduced to approximately 10 pipe diameters.

In Eq. 18.1, C and K are dimensionless factors. K represents the relative compressibility of the liquid. (Typical values are 1.4 for hot water; 1.5 for amine, glycol, and cold water; and 2.5 for hot oil.) Values of C are given in Table 18.3.

$$h_{ac} = \left(\frac{C}{K}\right)\left(\frac{L_{suction} v_{ave} n_{rpm}}{g}\right) \qquad 18.1$$

Table 18.2 *Typical v_{max}/v_{ave} Velocity Ratios*[a,b]

pump type	single-acting	double-acting
simplex	3.2	2.0
duplex	1.6	1.3
triplex	1.1	1.1
quadriplex	1.1	1.1
quintuplex and up	1.05	1.05

[a]Without stabilization. With properly sized stabilizers, use 1.05 to 1.1 for all cases.
[b]Multiply the values by 1.3 for metering pumps where lost fluid motion is relied on for capacity control.

Table 18.3 *Typical Acceleration Head C-Values*[a]

pump type	single-acting	double-acting
simplex	0.4	0.2
duplex	0.2	0.115
triplex	0.066	0.066
quadriplex	0.040	0.040
quintuplex and up	0.028	0.028

[a]Typical values for common connecting rod lengths and crank radii.

4. ROTARY PUMPS

Rotary pumps are *positive displacement* (PD) pumps that move fluid by means of screws, progressing cavities, gears, lobes, or vanes turning within a fixed casing (the *stator*). Rotary pumps are useful for high viscosities (up to 4×10^6 SSU for screw pumps). The rotation creates a cavity of fixed volume near the pump input; atmospheric or external pressure forces the liquid into that cavity. Near the outlet, the cavity is collapsed, forcing the liquid out. Figure 18.1 illustrates the external circumferential piston rotary pump.

Discharge from rotary pumps is relatively smooth. Acceleration head is negligible. Pulsation dampers and suction stabilizers are not required.

Slip in rotary pumps is the amount (sometimes expressed as a percentage) of each rotational fluid volume that "leaks" back to the suction line on each revolution. Slip reduces pump capacity. It is a function of clearance, differential pressure, and viscosity. Slip is proportional to the third power of the clearance between the rotating element and the casing. Slip decreases with increases in viscosity; it increases linearly with increases in differential pressure. Slip is not affected by rotational speed. The *volumetric efficiency* is defined by Eq. 18.2. Figure 18.2 illustrates the relationship between flow rate, speed, slip, and differential pressure.

$$\eta_v = \frac{Q_{actual}}{Q_{ideal}} = \frac{Q_{ideal} - Q_{slip}}{Q_{ideal}} \qquad 18.2$$

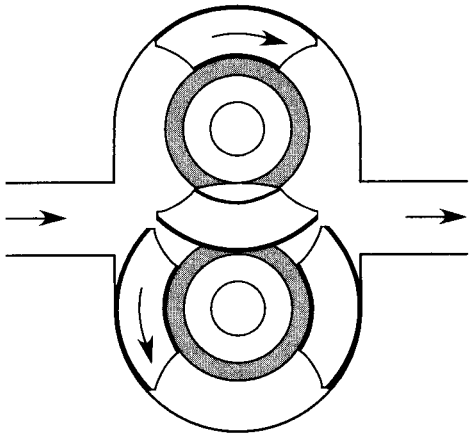

Figure 18.1 *External Circumferential Piston Rotary Pump*

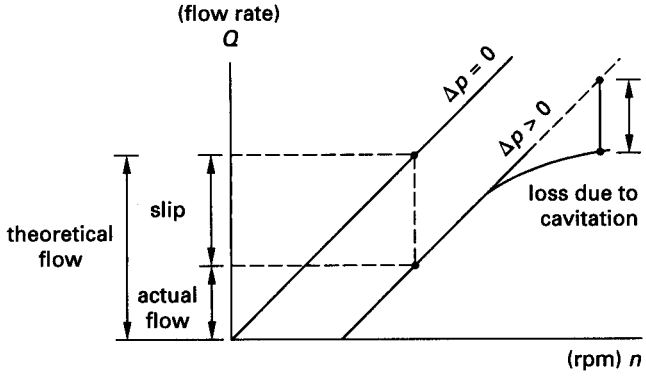

Figure 18.2 *Slip in Rotary Pumps*

Except for screw pumps, rotary pumps are generally not used for handling abrasive fluids or materials with suspended solids. Few rotary pumps are suitable when variable flow is required.

5. DIAPHRAGM PUMPS

Hydraulically operated *diaphragm pumps* have a diaphragm that completely separates the pumped fluid from the rest of the pump. A reciprocating plunger pressurizes and moves a hydraulic fluid that, in turn, flexes the diaphragm. Single-ball check valves in the suction and discharge lines determine the direction of flow during both phases of the diaphragm action.

Metering is a common application of diaphragm pumps. They have no packing and are essentially leak-proof. This makes them ideal when fugitive emissions are undesirable. Diaphragm pumps are suitable for pumping a wide range of materials, from liquefied gases to coal slurries, though the upper viscosity limit is approximately 3500 SSU. Within the limits of their reactivities, hazardous and reactive materials can also be handled.

Diaphragm pumps are limited by capacity, suction pressure, and discharge pressure and temperature. Because of their construction and size, most diaphragm pumps are limited to discharge pressures of 5000 psi (35 MPa) or less, and most high-capacity pumps are limited to 2000 psi (14 MPa). Suction pressures are similarly limited to 5000 psi (35 MPa). A minimum pressure of 3 to 9 psi (20 to 60 kPa) is often quoted as the minimum liquid-side pressure for metering applications.

The discharge is inherently pulsating, and the dampers or stabilizers are often used. (The acceleration head term is required when calculating NPSHR.) The discharge can be smoothed out somewhat by using two or three (i.e., duplex or triplex) plungers.

Diaphragms are commonly manufactured from stainless steel (type 316) and polytetrafluorethylene (PTFE) or other elastomers. PTFE diaphragms are suitable in the range of −50°F to 300°F (−45°C to 150°C), while metal diaphragms (and some ketone resin diaphragms) are used up to approximately 400°F (200°C), with life expectancy being reduced at higher temperatures. Although most diaphragm pumps usually operate below 200 spm (strokes per minute), diaphragm life will be improved by limiting the maximum speed to 100 spm.

6. TYPES OF CENTRIFUGAL PUMPS

Centrifugal pumps can be classified according to the way their impellers impart energy to the fluid. Each category of pump is suitable for a different application and (specific) speed range. Figure 18.3 illustrates a typical centrifugal pump and its schematic symbol.

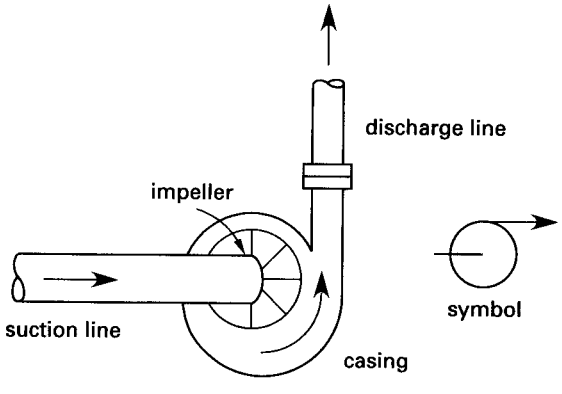

Figure 18.3 *Centrifugal Pump and Symbol*

Radial-flow impellers impart energy primarily by centrifugal force. Liquid enters the impeller at the hub and flows radially to the outside of the casing. Radial-flow pumps are suitable for adding high pressure at low fluid flow rates. *Axial-flow impellers* impart energy to the fluid by acting as compressors. Fluid enters and exits along the axis of rotation. Axial-flow pumps are suitable for adding low pressures at high fluid flow rates.[6]

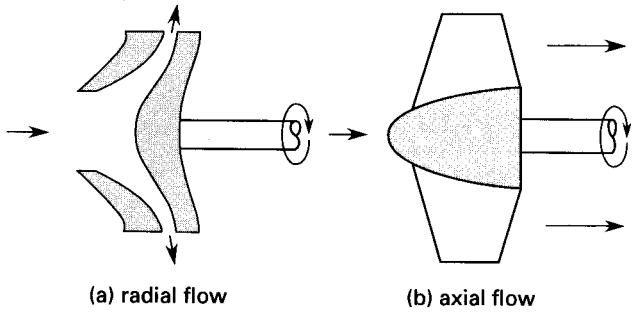

Figure 18.4 *Radial and Axial Flow Impellers*

Radial-flow pumps can be designed for either single- or double-suction operation. In a *single-suction pump*, fluid enters from only one side of the impeller. In a *double-suction pump*, fluid enters from both sides of the impeller.[7] (That is, the impeller is two-sided.) Operation is similar to having two single-suction pumps in parallel.

A *multiple-stage pump* consists of two or more impellers within a single casing. The discharge of one stage feeds the input of the next stage, and operation is similar to having several pumps in series. In this manner, higher heads are achieved than would be possible with a single impeller.

The *circular blade pitch* is the impeller's circumference divided by the number of impeller vanes. The impeller *tip speed* (not to be confused with the specific and suction specific speeds) is easily calculated from the impeller diameter and rotational speed. The impeller "tip speed" is actually the tangential velocity at the periphery. Tip speed is typically somewhat less than 1000 ft/sec (300 m/s).

$$v_{tip} = \frac{\pi D n}{60 \frac{\text{sec}}{\text{min}}} = \frac{D\omega}{2} \qquad 18.3$$

7. SEWAGE PUMPS

The primary consideration in choosing a pump for sewage and large solids is resistance to clogging. Centrifugal pumps should always be the single-section type with

[6]There is a third category of centrifugal pumps known as *mixed flow pumps*. Mixed flow pumps have operational characteristics between those of radial flow and axial flow pumps.

[7]The double-suction pump can handle a greater fluid flow rate than a single-suction pump with the same specific speed. Also, the double-suction pump will have a lower NPSHR.

nonclog, open impellers. (Double-suction pumps are prone to clogging because rags catch and wrap around the shaft extending through the impeller eye.) Clogging can be further minimized by limiting the number of impeller blades to two or three, providing for large passageways, and using a bar screen ahead of the pump.

Though made of heavy construction, nonclog pumps are constructed for ease of cleaning and repair. Horizontal pumps usually have a split casing, half of which can be removed for maintenance. A hand-sized cleanout opening may also be built into the casing. Although designed for long life, a sewage pump should normally be used with a grit chamber for prolonged bearing life.

The solids-handling capacity of a pump may be specified in terms of the largest sphere that can pass through it without clogging, usually about 80% of the inlet diameter. For example, a wastewater pump with a 6 in (150 mm) inlet should be able to pass a 4 in (100 mm) sphere. The pump must be capable of handling spheres with diameters slightly larger than the bar screen spacing.

Figure 18.5 shows a simplified wastewater pump installation. Not shown are instrumentation and water level measurement devices, baffles, lighting, drains for the dry well, electrical power, pump lubrication equipment, and access ports. (Totally submerged pumps do not require dry wells. However, such pumps without dry wells are more difficult to access, service, and repair.)

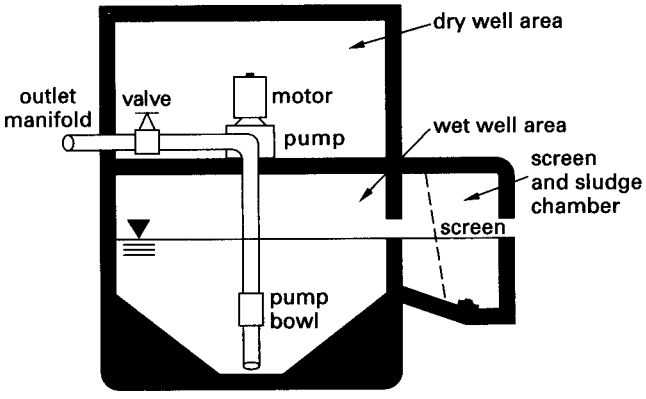

Figure 18.5 *Typical Wastewater Pump Installation (greatly simplified)*

The multiplicity and redundancy of pumping equipment is not apparent from Fig. 18.5. The number of pumps used in a wastewater installation largely depends on the expected demand, pump capacity, and design criteria for backup operation. Although there may be state and federal regulations affecting the design, it is considered good practice to install pumps in sets of two, with a third backup pump being available for each set of pumps that performs the same function. The number of pumps and their capacities should be able to handle the peak flow when one pump in the set is out of service.

8. SLUDGE PUMPS AND GRAVITY FLOW

Centrifugal and reciprocating pumps are extensively used for pumping sludge. Progressive cavity screw impeller pumps are also used.

As described in Sec. 28, the pumping power is proportional to the specific gravity. Accordingly, pumping power for dilute and well-digested sludges is typically only 10 to 25% higher than for water. However, most sludges are non-Newtonian fluids, often flow in a laminar mode, and have characteristics that may change with the season. Also, sludge characteristics change greatly during the pumping cycle. Therefore, engineering judgment and rules of thumb are often important in choosing sludge pumps. For example, a general rule is to choose sludge pumps capable of developing at least 50 to 100% excess head.

One method of determining the required pumping power is to multiply the power required for pumping pure water by a numerical factor. Empirical data is the best method of selecting this factor. Choice of initial values is a matter of judgment. Guidelines are listed in Table 18.4.

Table 18.4 *Pumping Power Multiplicative Factors*

solids concentration	digested sludge	untreated, primary, and concentrated sludge
0%	1.0	1.0
2%	1.2	1.4
4%	1.3	2.5
6%	1.7	4.1
8%	2.2	7.0
10%	3.0	10.0

Derived from *Wastewater Engineering: Treatment, Disposal, Reuse*, 3rd ed., by Metcalf & Eddy, et al., © 1991, with permission from The McGraw-Hill Companies.

Generally, sludge will thin out during a pumping cycle. The most dense sludge components will be pumped first, with more watery sludge appearing at the end of the pumping cycle. With a constant power input, the reduction in load at the end of pumping cycles may cause centrifugal pumps to operate far from the desired operating pump and experience overload failures. The operating point should be evaluated with high-, medium-, and low-density sludges.

To avoid cavitation, sludge pumps should always be under a positive suction head of at least 4 ft (1.2 m), and suction lifts should be avoided. The minimum diameters of suction and discharge lines for pumped sludge are typically 6 in (150 mm) and 4 in (100 mm), respectively.

Not all sludge is moved by pump action. Some installations rely on gravity flow to move sludge. The minimum diameter of sludge gravity transfer lines is typically 8 in (200 mm), and the recommended minimum slope is 3%.

To avoid clogging due to settling, flow should be above the transition from laminar to turbulent flow, known as the *critical velocity*. The critical velocity for most sludges is approximately 3.5 ft/sec (1.1 m/s). Velocities of 5 to 8 ft/sec (1.5 to 2.4 m/s) are typical and adequate.

9. TERMINOLOGY OF HYDRAULIC MACHINES

A pump will always have an inlet (designated the *suction*) and an outlet (designated the *discharge*). The subscripts s and d refer to the inlet and outlet of the pump, not of the pipeline.

All of the terms that are discussed in this section are *head* terms and, as such, have units of length. When working with hydraulic machines, it is common to hear such phrases as "a pressure head of 50 feet" and "a static discharge head of 15 meters" The term *head* is often substituted for pressure or pressure drop. Any head term (*pressure head, atmospheric head, vapor pressure head*, etc.) can be calculated from pressure by using Eq. 18.4.[8]

$$h = \frac{p}{\gamma} \qquad 18.4$$

$$h = \frac{p}{g\rho} \qquad \text{[SI]} \qquad 18.5(a)$$

$$h = \left(\frac{p}{\rho}\right) \times \left(\frac{g_c}{g}\right) \qquad \text{[U.S.]} \qquad 18.5(b)$$

Some of the terms used in the description of pipelines appear to be similar and may be initially confusing (e.g., suction head and total suction head). The following general rules will help to clarify the meanings.[9]

Rule 18.1: The word *suction* or *discharge* limits the quantity to the suction line or discharge line, respectively. The absence of either word implies that both the suction and discharge lines are included. Example: discharge head.

Rule 18.2: The word *static* means that static head only is included (not velocity head, friction head, etc.). Example: static suction head.

Rule 18.3: The word *total* means that static head, velocity head, and friction head are all included. (Note that total does not mean the combination of suction and discharge.) Example: total suction head.

[8]Equation 18.5 can be used to define *pressure head, atmospheric head*, and *vapor pressure head*, whose meanings and derivations should be obvious.

[9]The term *dynamic* is not as consistently applied as are the terms described in the rules. In particular, it is not clear whether friction head is to be included with the velocity head.

The following terms are commonly encountered.

- *friction head* (h_f): The head required to overcome resistance to flow in the pipes, fittings, valves, entrances, and exits.

$$h_f = \frac{fLv^2}{2Dg} \qquad 18.6$$

- *velocity head* (h_v): The specific kinetic energy of the fluid. Also known as *dynamic head.*

$$h_v = \frac{v^2}{2g} \qquad 18.7$$

- *static suction head* ($h_{z(s)}$): The vertical distance above the centerline of the pump inlet to the free level of the fluid source. If the free level of the fluid is below the pump inlet, h_z will be negative and is known as *static suction lift.*

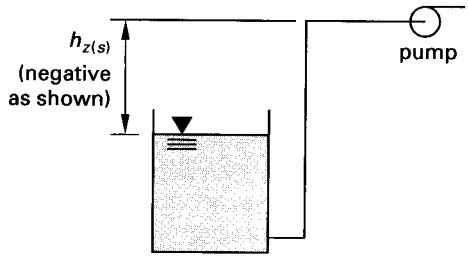

Figure 18.6 Static Suction Lift

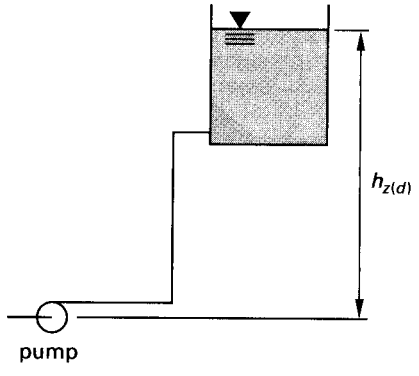
- *static discharge head* ($h_{z(d)}$): The vertical distance above the centerline of the pump inlet to the point of free discharge or surface level of the discharge tank.



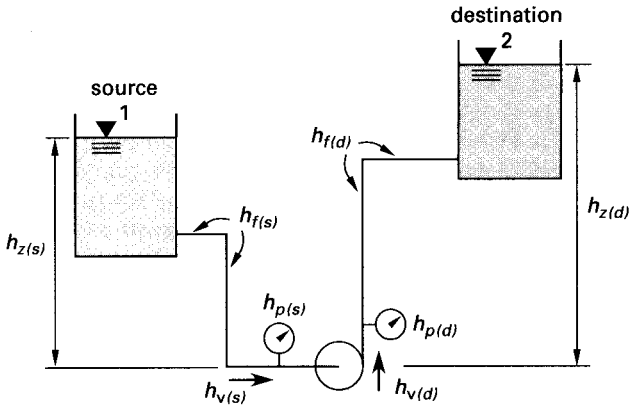


Figure 18.7 Static Discharge Head

Example 18.1

Write the symbolic equations for the following terms: (a) total suction head, (b) total discharge head, and (c) total head.

Solution

(a) The total suction head at the pump inlet is the sum of static (pressure) head and velocity head at the pump suction.

$$h_{t(s)} = h_{p(s)} + h_{v(s)}$$

Total suction head can also be calculated from the conditions existing at the source (1), in which case suction line friction would also be considered. (With an open reservoir, $h_{p(1)}$ will be zero if gage pressures are used, and $h_{v(1)}$ will be zero if the source is large.)

$$h_{t(s)} = h_{p(1)} + h_{z(s)} + h_{v(1)} - h_{f(s)}$$

(b) The total discharge head at the pump outlet is the sum of the static (pressure) and velocity heads at the pump outlet. Friction head is zero since the fluid has not yet traveled through any length of pipe when it is discharged.

$$h_{t(d)} = h_{p(d)} + h_{v(d)}$$

The total discharge head can also be evaluated at the destination (2) if the friction head, $h_{f(d)}$, between the discharge and the destination is known. (With an open reservoir, $h_{p(2)}$ will be zero if gage pressures are used, and $h_{v(2)}$ will be zero if the destination is large.)

$$h_{t(d)} = h_{p(2)} + h_{z(d)} + h_{v(2)} + h_{f(d)}$$

(c) The total head added by the pump is the total discharge head less the total suction head. Assuming suction from and discharge to reservoirs exposed to the atmosphere and assuming negligible reservoir velocities,

$$h_t = h_A = h_{t(d)} - h_{t(s)} \approx h_{z(d)} - h_{z(s)} + h_{f(d)} + h_{f(s)}$$

10. PUMPING POWER

The energy (head) added by a pump can be determined from the difference in total energy on either side of the pump. Writing the Bernoulli equation for the discharge and suction conditions produces Eq. 18.8, an equation for the *total dynamic head*, often abbreviated TDH.

$$h_A = h_t = h_{t(d)} - h_{t(s)} \qquad 18.8$$

$$h_A = \frac{p_d - p_s}{\rho g} + \frac{v_d^2 - v_s^2}{2g} + z_d - z_s \qquad \text{[SI]} \quad 18.9(a)$$

$$h_A = \frac{(p_d - p_s)g_c}{\rho g} + \frac{v_d^2 - v_s^2}{2g} + z_d - z_s \qquad \text{[U.S.]} \quad 18.9(b)$$

In most applications, the change in velocity and potential heads is either zero or small in comparison to the increase in pressure head. Equation 18.9 then reduces to Eq. 18.10.

$$h_A = \frac{p_d - p_s}{\rho g} \qquad \text{[SI]} \quad 18.10(a)$$

$$h_A = \left(\frac{p_d - p_s}{\rho}\right) \times \left(\frac{g_c}{g}\right) \qquad \text{[U.S.]} \quad 18.10(b)$$

It is important to recognize that the variables in Eqs. 18.9 and 18.10 refer to the conditions at the pump's immediate inlet and discharge, not to the distant ends of the suction and discharge lines. However, the total dynamic head added by a pump can be calculated in another way. For example, for a pump raising water from one open reservoir to another, the total dynamic head would consist of the total elevation rise, the velocity head (often negligible), and the friction losses in the suction and discharge lines.

The head added by the pump can also be calculated from the impeller and fluid speeds. Equation 18.11 is useful for radial- and mixed-flow pumps for which the incoming fluid has little or no rotational velocity component (i.e., up to a specific speed of approximately 2000 U.S. or 40 SI). In Eq. 18.11, v_{impeller} is the tangential impeller velocity at the radius being considered, and v_{fluid} is the average tangential velocity imparted to the fluid by the impeller. The impeller efficiency, η_{impeller}, is typically 0.85 to 0.95. This is much higher than the total pump efficiency (Sec. 11) because it does not include mechanical and fluid friction losses.

$$h_A = \frac{\eta_{\text{impeller}} v_{\text{impeller}} v_{\text{fluid}}}{g} \qquad 18.11$$

The pumping power depends on the head added (h_A) and the mass flow rate. For example, the product $\dot{m}\, h_A$ has the units of foot-pounds per second (in customary U.S. units), which can be easily converted to horsepower. Pump output power is known as *hydraulic power* or *water power*. Hydraulic power is the net power actually transferred to the fluid.

Horsepower is the unit of power in the United States and other non-SI countries, which gives rise to the terms *hydraulic horsepower* and *water horsepower*, WHP. Various relationships for finding the hydraulic horsepower are given in Table 18.5.

The unit of power in SI units is the watt (kilowatt). Table 18.6 can be used to determine *hydraulic kilowatts*, WkW.

Table 18.5 *Hydraulic Horsepower Equations*[a]

	Q (gal/min)	$\dot{m}$ (lbm/sec)	$\dot{V}$ (ft^3/sec)
h_A in feet	$\frac{h_A Q(SG)}{3956}$	$\left(\frac{h_A \dot{m}}{550}\right)\times\left(\frac{g}{g_c}\right)$	$\frac{h_A \dot{V}(SG)}{8.814}$
Δp in psi	$\frac{\Delta p Q}{1714}$	$\left[\frac{\Delta p \dot{m}}{(238.3)(SG)}\right]\times\left(\frac{g}{g_c}\right)$	$\frac{\Delta p \dot{V}}{3.819}$
Δp in psf	$\frac{\Delta p Q}{2.468\times 10^5}$	$\left[\frac{\Delta p \dot{m}}{(34{,}320)(SG)}\right]\times\left(\frac{g}{g_c}\right)$	$\frac{\Delta p \dot{V}}{550}$
W in $\frac{\text{ft-lbf}}{\text{lbm}}$	$\frac{WQ(SG)}{3956}$	$\frac{W\dot{m}}{550}$	$\frac{W\dot{V}(SG)}{8.814}$

(Multiply horsepower by 0.7457 to obtain kilowatts.)
[a]Table 18.5 is based on $\rho_{water} = 62.4\,lbm/ft^3$ and $g = 32.2\,ft/sec^2$.

Table 18.6 *Hydraulic Kilowatt Equations*[a]

	Q (L/s)	$\dot{m}$ (kg/s)	$\dot{V}$ (m^3/s)
h_A in meters	$\frac{(9.81)h_A Q(SG)}{1000}$	$\frac{(9.81)h_A \dot{m}}{1000}$	$(9.81)h_A \dot{V}(SG)$
Δp in kPa	$\frac{\Delta p Q}{1000}$	$\frac{\Delta p \dot{m}}{1000(SG)}$	$\Delta p \dot{V}$
W in $\frac{\text{J}}{\text{kg}}$	$\frac{WQ(SG)}{1000}$	$\frac{W\dot{m}}{1000}$	$W\dot{V}(SG)$

(Multiply kilowatts by 1.341 to obtain horsepower.)
[a]Table 18.6 is based on $\rho_{water} = 1000\,kg/m^3$ and $g = 9.81\,m/s^2$.

Example 18.2

A pump adds 550 ft of pressure head to 100 lbm/sec of water. (a) Complete the following table of performance data. (b) What is the hydraulic power in horsepower and kilowatts? (Assume $\rho = 62.4\,lbm/ft^3$ or $1000\,kg/m^3$, and $g = 9.81\,m/s^2$.)

item	customary U.S.	SI
$\dot{m}$	100 lbm/sec	___ kg/s
h	550 ft	___ m
Δp	___ lbf/ft^2	___ kPa
$\dot{V}$	___ ft^3/sec	___ m^3/s
W	___ ft-lbf/lbm	___ J/kg
P	___ hp	___ kW

Solution

(a) Work initially with the customary U.S. data.

$$\Delta p = \rho h \times \left(\frac{g}{g_c}\right) = \left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)(550\ \text{ft}) \times \left(\frac{g}{g_c}\right)$$
$$= 34{,}320\ \text{lbf/ft}^2$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{100\ \frac{\text{lbm}}{\text{sec}}}{62.4\ \frac{\text{lbm}}{\text{ft}^3}} = 1.603\ \text{ft}^3/\text{sec}$$

$$W = h \times \left(\frac{g}{g_c}\right) = 550\ \text{ft-lbf/lbm}$$

Now, convert to SI units.

$$\dot{m} = \frac{100\ \frac{\text{lbm}}{\text{sec}}}{2.201\ \frac{\text{lbm}}{\text{kg}}} = 45.43\ \text{kg/s}$$

$$h = \frac{550\ \text{ft}}{3.281\ \frac{\text{ft}}{\text{m}}} = 167.6\ \text{m}$$

$$\Delta p = \left(34{,}320\ \frac{\text{lbf}}{\text{ft}^2}\right)\left(\frac{1}{144\ \frac{\text{in}^2}{\text{ft}^2}}\right)\left(6.895\ \frac{\text{kPa}}{\frac{\text{lbf}}{\text{in}^2}}\right)$$
$$= 1643\ \text{kPa}$$

$$\dot{V} = \left(1.603\ \frac{\text{ft}^3}{\text{sec}}\right)\left(0.0283\ \frac{\text{m}^3}{\text{ft}^3}\right) = 0.0454\ \text{m}^3/\text{s}$$

$$W = \left(550\ \frac{\text{ft-lbf}}{\text{lbm}}\right)\left(1.356\ \frac{\text{J}}{\text{ft-lbf}}\right)\left(2.201\ \frac{\text{lbm}}{\text{kg}}\right)$$
$$= 1642\ \text{J/kg}$$

(b) From Table 18.5, the hydraulic horsepower is

$$\text{WHP} = \frac{h_A \dot{m}}{550} \times \left(\frac{g}{g_c}\right)$$
$$= \left[\frac{(550\ \text{ft})\left(100\ \frac{\text{lbm}}{\text{sec}}\right)}{550\ \frac{\text{ft-lbf}}{\text{hp-sec}}}\right] \times \left(\frac{g}{g_c}\right)$$
$$= 100\ \text{hp}$$

From Table 18.6, the power is

$$\text{WkW} = \frac{\Delta p \dot{m}}{(1000)(SG)} = \frac{(1643\,\text{kPa})\left(45.43\ \frac{\text{kg}}{\text{s}}\right)}{\left(1000\ \frac{\text{W}}{\text{kW}}\right)(1.0)}$$
$$= 74.6\,\text{kW}$$

11. PUMPING EFFICIENCY

Hydraulic power is the net energy actually transferred to the fluid per unit time. The input power delivered by the motor to the pump is known as the *brake pump power*. (For example, the term *brake horsepower*, bhp, is commonly used.) Due to frictional losses between the fluid and the pump and mechanical losses in the pump itself, the brake pump power will be greater than the hydraulic power.

The difference between brake and hydraulic power is accounted for by the pump efficiency, η_p. (Figure 18.8 gives typical pump efficiencies as a function of the pump's specific speed. The difference between the brake and hydraulic powers is known as the *friction power* (or *friction horsepower*).

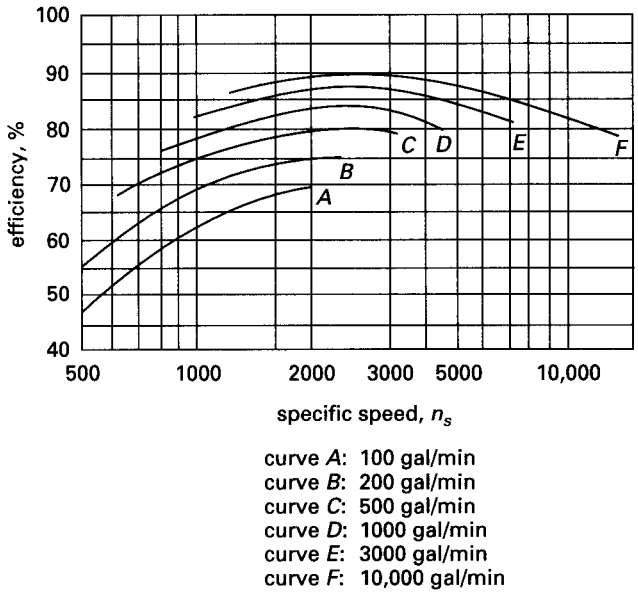

Figure 18.8 *Average Pump Efficiency Versus Specific Speed*

$$\text{brake pump power} = \frac{\text{hydraulic power}}{\eta_p} \qquad 18.12$$

$$\text{friction power} = \text{brake pump power} - \text{hydraulic power} \qquad 18.13$$

Pumping efficiency is not constant for any specific pump; rather, it depends on the operating point (Sec. 23) and the speed of the pump. A specific pump's characteristic efficiency curves will be published by its manufacturer.

With pump characteristic curves given by the manufacturer, the efficiency is not determined from the intersection of the system curve (Sec. 22) and the efficiency curve. Rather, the efficiency is a function of only the flow rate. Therefore, the operating efficiency is read from the efficiency curve directly above or below the operating point (Sec. 23).

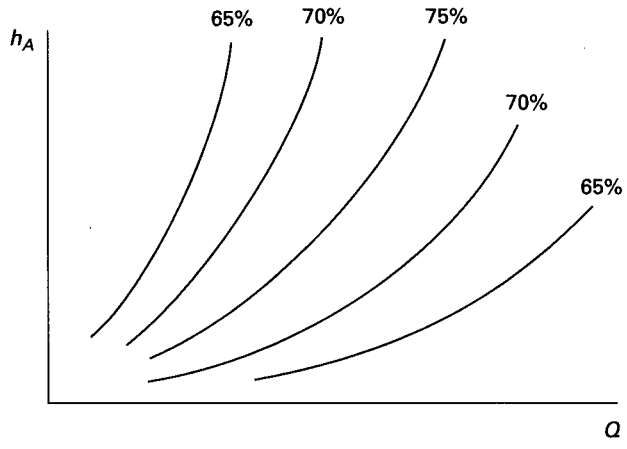

Figure 18.9 *Typical Centrifugal Pump Efficiency Curves*

Unfortunately, efficiency curves published by a manufacturer may not be representative of the actual installed efficiency. The manufacturer's efficiency may not include such losses in the suction elbow, discharge diffuser, couplings, bearing frame, seals, or pillow blocks. Up to 15% of the motor horsepower may be lost to these factors. Therefore, the manufacturer should be requested to provide the pump's installed *wire-to-water efficiency* (i.e., the fraction of the electrical power drawn that is converted to hydraulic power).

The pump must be driven by an engine or motor.[10] The power delivered to the motor is greater than the power delivered to the pump, as accounted for by the motor efficiency, η_m. If the pump motor is electrical, its input power requirements will be stated in kilowatts.[11]

$$\text{motor input power} = \frac{\text{brake pump power}}{\eta_m} \qquad 18.14$$

$$(\text{motor input power})_{\text{kW}} = \frac{0.7457 \times (\text{brake pump power})_{\text{hp}}}{\eta_m} \qquad 18.15$$

The *overall efficiency* of the pump installation is the product of the pump and motor efficiencies.

$$\eta = \eta_p \eta_m = \frac{\text{hydraulic horsepower}}{\text{motor horsepower}} \qquad 18.16$$

12. COST OF ELECTRICITY

The power utilization of pump motors is usually measured in kilowatts. The kilowatt usage represents the rate that energy is transferred by the pump motor. The total amount of work, W, done by the pump motor is found by multiplying the rate of energy usage by the length of time the pump is in operation.

$$W = Pt \qquad 18.17$$

[10]The source of power is sometimes called the *prime mover*.
[11]A *watt* is a joule per second.

Although the units horsepower-hours are occasionally encountered, it is more common to measure electrical work in *kilowatt-hours* (kW-hr). Accordingly, the cost of electrical energy is stated per kW-hr (e.g., \$0.10 per kW-hr).

$$\text{cost} = \frac{W_{\text{kW-hr}} \times \text{cost per kW-hr}}{\eta_m} \qquad 18.18$$

13. STANDARD MOTOR SIZES AND SPEEDS

An effort should be made to specify standard motor sizes when selecting the source of pumping power. Table 18.7 lists NEMA (National Electrical Manufacturers Association) standard motor sizes by horsepower *nameplate rating*.[12] The rated horsepower is the maximum power the motor can provide without incurring damage. Other motor sizes may also be available by special order.

Table 18.7 *NEMA Standard Motor Sizes (brake horsepower)*

$\frac{1}{8}$,	$\frac{1}{6}$,	$\frac{1}{4}$,	$\frac{1}{3}$				
0.5,	0.75,	1,	1.5,	2,	3,	5,	7.5
10,	15,	20,	25,	30,	40,	50,	60
75,	100,	125,	150,	200,	250,	300,	350
400,	450,	500,	600,	700,	800,	900,	1000
1250,	1500,	1750,	2000,	2250,	2500,	2750,	3000
3500,	4000,	4500,	5000				

Larger horsepower motors are usually three-phase induction motors. The *synchronous speed*, n in rpm, of such motors is the speed of the rotating field, which depends on the number of poles per stator phase and the frequency, f. The number of poles must be an even number. The frequency is typically 60 Hz (hertz, previously cycles per second), as in the United States, or 50 Hz, as in European countries. Table 18.8 lists common synchronous speeds.

$$n = \frac{120 \times f}{\text{no. of poles}} \qquad 18.19$$

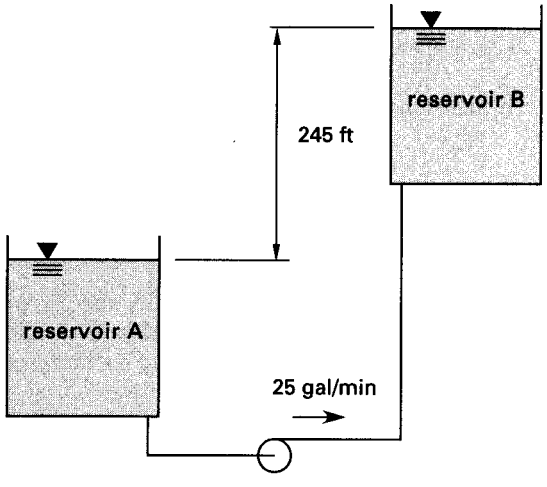
Table 18.8 *Common Synchronous Speeds*

number of poles	n (rpm) 60 Hz	50 Hz
2	3600	3000
4	1800	1500
6	1200	1000
8	900	750
10	720	600
12	600	500
14	514	428
18	400	333
24	300	250
48	150	125

[12]The nameplate rating gets its name from the information stamped on the motor's identification plate. Besides the horsepower rating, other nameplate data used to classify the motor are the service class, voltage, full-load current, speed, number of phases, frequency of the current, and maximum ambient temperature (or, for older motors, the motor temperature rise).

Induction motors do not run at their synchronous speeds when loaded. Rather, they run at slightly less than synchronous speed. The deviation is known as the *slip*. Slip is typically around 4% and is seldom greater than 10% at full load for motors in the 1 to 75 hp range.

$$\begin{matrix}\text{slip} \\ \text{(in rpm)}\end{matrix} = \text{synchronous speed} - \text{actual speed} \qquad 18.20$$



$$\begin{matrix}\text{percent} \\ \text{slip}\end{matrix} = 100\% \times \frac{\text{synchronous speed} - \text{actual speed}}{\text{synchronous speed}} \qquad 18.21$$

Induction motors may also be specified in terms of their kVA (kilovolt-amp) ratings. The kVA rating is not the same as the power in kilowatts, although one can be derived from the other if the motor's power factor is known. Such power factors typically range from 0.8 to 0.9, depending on the installation and motor size.

$$\text{kVA rating} = \frac{\text{motor power in kW}}{\text{power factor}} \qquad 18.22$$

Example 18.3

A pump driven by an electrical motor moves 25 gal/min of water from reservoir A to reservoir B, lifting the water a total of 245 ft. The efficiencies of the pump and motor are 64% and 84%, respectively. Electricity costs \$0.08/kW-hr. Neglect velocity head, friction, and minor losses. (a) What size motor is required? (b) How much does it cost to operate the pump for 6 hr?

Solution

(a) The head added is 245 ft.

From Table 18.5, the motor power required is

$$P = \frac{h_A Q(\text{SG})}{3956\eta_p} = \frac{(245 \text{ ft})\left(25 \frac{\text{gal}}{\text{min}}\right)(1.0)}{(3956)(0.64)}$$
$$= 2.42 \text{ hp}$$

From Table 18.7, select a 3 hp motor.

(b) From Eqs. 18.17 and 18.18,

$$\text{cost} = \text{cost per kW-hr} \times \left(\frac{Pt}{\eta_m}\right)$$
$$= \frac{\left(0.08 \frac{\$}{\text{kW-hr}}\right)\left(0.7457 \frac{\text{kW}}{\text{hp}}\right)(2.42 \text{ hp})(6 \text{ hr})}{0.84}$$
$$= \$1.03$$

14. PUMP SHAFT LOADING

The torque on a pump or motor shaft, brake power, and speed are all related. The power used in Eqs. 18.23 through 18.25 is the brake (shaft) power, not the hydraulic power.

$$T_{\text{in-lbf}} = \frac{63{,}025 \times P_{\text{hp}}}{n} \qquad 18.23$$

$$T_{\text{ft-lbf}} = \frac{5252 \times P_{\text{hp}}}{n} \qquad 18.24$$

$$T_{\text{N·m}} = \frac{9549 \times P_{\text{kW}}}{n} \qquad 18.25$$

The torque can also be calculated from the change in momentum of the fluid flow. For radial impellers, the fluid enters through the eye and is turned 90°. The direction change is related to the increase in momentum and the shaft torque. When fluid is introduced axially through the eye of the impeller, the tangential velocity at the inlet (eye), $v_{t,i}$, is zero.[13]

$$T = \left(\frac{\dot{m}}{g_c}\right)\left(v_{t(d)} r_{\text{impeller}} - v_{t(i)} r_{\text{eye}}\right) \qquad 18.26$$

Centrifugal pumps may be driven directly from a motor, or a speed changer may be used. Rotary pumps generally require a speed reduction. *Gear motors* have integral speed reducers. V-belt drives are widely used because of their initial low cost, although timing belts and chains can be used in some applications.

When a belt or chain is used, the pump's and motor's maximum overhung loads must be checked. This is particularly important for high-power, low-speed applications (such as rotary pumps). *Overhung load* is the side load (force) put on shafts and bearings. The overhung load is calculated from Eq. 18.27. The empirical factor K is 1.0 for chain drives, 1.25 for timing belts, and 1.5 for V-belts.

$$\text{overhung load} = \frac{2KT}{D_{\text{sheave}}} \qquad 18.27$$

If a direct drive cannot be used and the overhung load is excessive, the installation can incorporate a jack shaft or outboard bearing.

Example 18.4

A centrifugal pump delivers 275 lbm/sec (125 kg/s) of water while turning at 850 rpm. The impeller has straight radial vanes and an outside diameter of 10 in (25.4 cm). Water enters the impeller through the eye. The driving motor develops 30 hp (22 kW). What are the (a) theoretical torque, (b) pump efficiency, and (c) total dynamic head?

SI Solution

(a) From Eq. 18.3, the impeller's tangential velocity is

$$v_t = \frac{\pi D n}{60 \frac{\text{s}}{\text{min}}} = \frac{\pi(25.4 \text{ cm})(850 \text{ rpm})}{\left(60 \frac{\text{s}}{\text{min}}\right)\left(100 \frac{\text{cm}}{\text{m}}\right)}$$
$$= 11.3 \text{ m/s}$$

Since water enters axially, the incoming water has no tangential component. From Eq. 18.26,

$$T = \dot{m} v_{t(d)} r_{\text{impeller}}$$
$$= \frac{\left(125 \frac{\text{kg}}{\text{s}}\right)\left(11.3 \frac{\text{m}}{\text{s}}\right)\left(\frac{25.4 \text{ cm}}{2}\right)}{100 \frac{\text{cm}}{\text{m}}}$$
$$= 179.4 \text{ N·m}$$

(b) From Eq. 18.25, the theoretical power is

$$P_{\text{kW}} = \frac{n T_{\text{N·m}}}{9549} = \frac{(850 \text{ rpm})(179.4 \text{ N·m})}{9549}$$
$$= 15.97 \text{ kW}$$

The pump efficiency is

$$\eta_p = \frac{P_{\text{theoretical}}}{P_{\text{actual}}}$$
$$= \frac{15.97 \text{ kW}}{22 \text{ kW}} = 0.726 \quad (72.6\%)$$

[13] The tangential component of fluid velocity is sometimes referred to as the *velocity of whirl*.

(c) From Table 18.6, the total dynamic head is

$$h_A = \frac{P_{\text{kW}}\left(1000\ \frac{\text{W}}{\text{kW}}\right)}{\dot{m}\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}$$

$$= \frac{(15.97\ \text{kW})\left(1000\ \frac{\text{W}}{\text{kW}}\right)}{\left(125\ \frac{\text{kg}}{\text{s}}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}$$

$$= 13.0\ \text{m}$$

Customary U.S. Solution

(a) From Eq. 18.3, the impeller's tangential velocity is

$$\text{v}_t = \frac{\pi D n}{60\ \frac{\text{sec}}{\text{min}}} = \frac{\pi(10\ \text{in})(850\ \text{rpm})}{\left(60\ \frac{\text{sec}}{\text{min}}\right)\left(12\ \frac{\text{in}}{\text{ft}}\right)}$$

$$= 37.08\ \text{ft/sec}$$

Since water enters axially, the incoming water has no tangential component. From Eq. 18.26,

$$T = \frac{\dot{m}\text{v}_{t(d)} r_{\text{impeller}}}{g_c}$$

$$= \frac{\left(275\ \frac{\text{lbm}}{\text{sec}}\right)\left(37.08\ \frac{\text{ft}}{\text{sec}}\right)\left(\frac{10\ \text{in}}{2}\right)}{\left(32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)\left(12\ \frac{\text{in}}{\text{ft}}\right)}$$

$$= 131.9\ \text{ft-lbf}$$

(b) From Eq. 18.24, the theoretical power is

$$P_{\text{hp}} = \frac{T_{\text{ft-lbf}} n}{5252}$$

$$= \frac{(131.9\ \text{ft-lbf})(850\ \text{rpm})}{5252} = 21.35\ \text{hp}$$

The pump efficiency is

$$\eta_p = \frac{P_{\text{theoretical}}}{P_{\text{actual}}}$$

$$= \frac{21.35\ \text{hp}}{30\ \text{hp}} = 0.712\ \ (71.2\%)$$

(c) From Table 18.5, the total dynamic head is

$$h_A = \left[\frac{\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)(P_{\text{hp}})}{\dot{m}}\right] \times \left(\frac{g_c}{g}\right)$$

$$= \left[\frac{\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)(21.35\ \text{hp})}{275\ \frac{\text{lbm}}{\text{sec}}}\right]$$

$$\times \left(\frac{32.2\ \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}{32.2\ \frac{\text{ft}}{\text{sec}^2}}\right)$$

$$= 42.7\ \text{ft}$$

15. SPECIFIC SPEED

The capacity and efficiency of a centrifugal pump are partially governed by the impeller design. For a desired flow rate and added head, there will be one optimum impeller design. The quantitative index used to optimize the impeller design is known as *specific speed*, n_s, also known as *impeller specific speed*. Table 18.9 lists the impeller designs that are appropriate for different specific speeds.[14]

Table 18.9 *Specific Speed versus Impeller Design*

approximate range of specific speed (rpm)		
customary U.S. units	SI units	impeller type
500 to 1000	10 to 20	radial vane
2000 to 3000	40 to 60	Francis (mixed) vane
4000 to 7000	80 to 140	mixed flow
9000 and above	180 and above	axial flow

Highest heads per stage are developed at low specific speeds. However, for best efficiency, specific speed should be greater than 650 (13 in SI units). If the specific speed for a given set of conditions drops below 650 (13), a multiple-stage pump should be selected.[15]

[14] Specific speed is useful for more than just selecting an impeller type. Maximum suction lift, pump efficiency, and net positive suction head required (NPSHR) can be correlated with specific speed.

[15] Advances in *partial emission, forced vortex centrifugal pumps* allow operation down to specific speeds of 150 (3 in SI). Such pumps have been used for low-flow, high-head applications, such as high-pressure petrochemical cracking processes.

Specific speed is a function of a pump's capacity, head, and rotational speed at peak efficiency, as shown in Eq. 18.28. For a given pump and impeller configuration, the specific speed remains essentially constant over a range of flow rates and heads.

While specific speed is not dimensionless, the units are meaningless. Specific speed may be assigned units of rpm, but most often it is expressed simply as a pure number. (Q or $\dot{V}$ in Eq. 18.28 is half of the full flow rate for double-suction pumps.)

$$n_s = \frac{n\sqrt{\dot{V}}}{(h_A)^{0.75}} \qquad \text{[SI]} \qquad 18.28(a)$$

$$n_s = \frac{n\sqrt{Q}}{(h_A)^{0.75}} \qquad \text{[U.S.]} \qquad 18.28(b)$$

The numerical range of acceptable performance for each impeller type is redefined when SI units are used. The SI specific speed is obtained by dividing the customary U.S. specific speed by 51.66.

A common definition of specific speed is the speed (in rpm) at which a *homologous pump* would have to turn in order to deliver one gallon per minute at one foot total added head.[16] This definition is implicit to Eq. 18.28 but is not very useful otherwise.

Specific speed can be used to determine the type of impeller needed. Once a pump is selected, its specific speed and Eq. 18.28 can be used to determine other operational parameters (e.g., maximum rotational speed). Specific speed can be used with Fig. 18.7 to obtain an approximate pump efficiency.

Example 18.5

A centrifugal pump powered by a direct-drive induction motor is needed to discharge 150 gal/min against a 300 ft total head when turning at the fully loaded speed of 3500 rpm. What type of pump should be selected?

Solution

From Eq. 18.28, the specific speed is

$$n_s = \frac{n\sqrt{Q}}{(h_A)^{0.75}} = \frac{3500\sqrt{150}}{(300)^{0.75}} = 595$$

From Table 18.9, the pump should be a radial vane type. However, pumps achieve their highest efficiencies when specific speed exceeds 650. (See Fig. 18.8.) To increase the specific speed, the rotational speed can be increased, or the total added head can be decreased. Since the pump is direct-driven and 3600 rpm is the maximum speed for induction motors (see Table 18.8), the total added head should be divided evenly between two stages, or two pumps should be used in series.

In a two-stage system, the specific speed would be

$$n_s = \frac{3500\sqrt{150}}{(150)^{0.75}} = 1000$$

This is satisfactory for a radial vane pump.

Example 18.6

An induction motor turning at 1200 rpm is to be selected to drive a single-stage, single-suction centrifugal water pump through a direct drive. The total dynamic head added by the pump is 26 ft. The flow rate is 900 gal/min. What size motor should be selected?

Solution

The specific speed is

$$n_s = \frac{n\sqrt{Q}}{(h_A)^{0.75}} = \frac{1200\sqrt{900}}{(26)^{0.75}} = 3127$$

From Fig. 18.8, the pump efficiency will be approximately 82%.

From Table 18.5, the minimum motor horsepower is

$$P_{\text{hp}} = \frac{h_A Q(\text{SG})}{\left(3956\ \frac{\text{ft-gal}}{\text{hp-min}}\right)\eta_p} = \frac{(26\text{ ft})\left(900\ \frac{\text{gal}}{\text{min}}\right)(1.0)}{\left(3956\ \frac{\text{ft-gal}}{\text{hp-min}}\right)(0.82)} = 7.2\text{ hp}$$

Example 18.7

A single-stage pump driven by a 3600 rpm motor is currently delivering 150 gal/min. The total dynamic head is 430 ft. What would be the approximate increase in efficiency if the single-stage pump is replaced by a double-stage pump?

Solution

The specific speed is

$$n_s = \frac{n\sqrt{Q}}{(h_A)^{0.75}} = \frac{3600\sqrt{150}}{(430)^{0.75}} = 467$$

[16] *Homologous pumps* are geometrically similar. This means that each pump is a scaled up or down version of the others. Such pumps are said to belong to a *homologous family*.

From Fig. 18.8, the approximate efficiency is 45%.

In a two-stage pump, each stage adds half of the head. The specific speed per stage would be

$$n_s = \frac{n\sqrt{Q}}{(h_A)^{0.75}} = \frac{3600\sqrt{150}}{\left(\frac{430}{2}\right)^{0.75}}$$

$$= 785$$

From Fig. 18.8, the efficiency for this configuration is approximately 60%.

The increase in efficiency is 60% − 45% = 15%. Whether or not the cost of multistaging is worthwhile in this low-volume application would have to be determined.

16. CAVITATION

Cavitation is the spontaneous vaporization of the fluid, resulting in a degradation of pump performance. If the fluid pressure is less than the vapor pressure, small pockets of vapor will form. These pockets usually form only within the pump itself, although cavitation slightly upstream within the suction line is also possible. As the vapor pockets reach the surface of the impeller, the local high fluid pressure collapses them. Noise, vibration, impeller pitting, and structural damage to the pump casing are manifestations of cavitation.

Cavitation can be caused by any of the following conditions.

- discharge head far below the pump head at peak efficiency
- high suction lift or low suction head
- excessive pump speed
- high liquid temperature (i.e., high vapor pressure)

17. NET POSITIVE SUCTION HEAD

The occurrence of cavitation is predictable. Cavitation will occur when the net pressure in the fluid drops below the vapor pressure. This criterion is commonly stated in terms of head: Cavitation occurs when the available head is less than the required head for satisfactory operation.

$$\text{available head} < \text{required head} \quad \left[\begin{array}{c}\text{criterion for}\\ \text{cavitation}\end{array}\right]$$

The minimum fluid energy required at the pump inlet for satisfactory operation (i.e., the required head) is known as the *net positive suction head required*, NPSHR.[17] NPSHR is a function of the pump and will be given by the pump manufacturer as part of the pump performance data.[18] NPSHR is dependent on the flow rate. However, if NPSHR is known for one flow rate, it can be determined for another flow rate from Eq. 18.29.

$$\frac{\text{NPSHR}_2}{\text{NPSHR}_1} = \left(\frac{Q_2}{Q_1}\right)^2 \qquad 18.29$$

Net positive suction head available, NPSHA, is the actual fluid energy at the inlet. There are two different methods for calculating NPSHA, both of which are correct and yield identical answers. Equation 18.30(a) is based on the conditions at the fluid surface at the top of the fluid source (e.g., tank or reservoir). There is a potential energy term but no kinetic energy term. Equation 18.30(b) is based on the conditions at the immediate entrance (suction, subscript s) to the pump. At that point, some of the potential head has been converted to velocity head. Frictional losses are implicitly part of the reduced pressure head, as is the atmospheric pressure head. The effect of higher altitudes is explicit in Eq. 18.30(a) and implicit in Eq. 18.30(b).

$$\text{NPSHA} = h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \qquad 18.30(a)$$

$$\text{NPSHA} = h_{p(s)} + h_{\text{v}(s)} - h_{\text{vp}} \qquad 18.30(b)$$

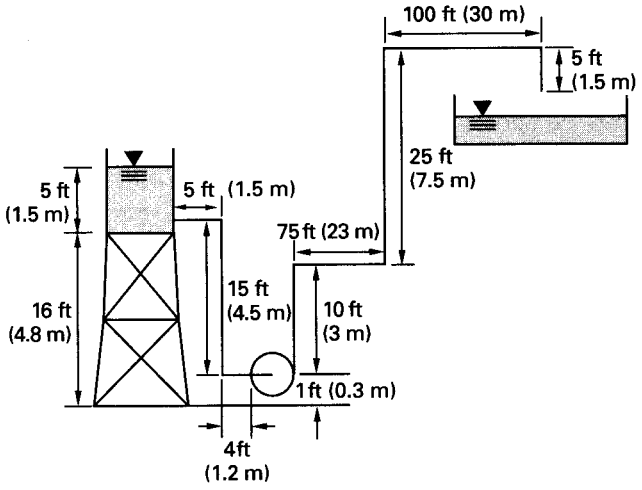
The net positive suction head available (NPSHA) for most positive displacement pumps includes a term for acceleration head.[19]

$$\text{NPSHA} = h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} - h_{\text{ac}} \qquad 18.31$$

$$\text{NPSHA} = h_{p(s)} + h_{\text{v}(s)} - h_{\text{vp}} - h_{\text{ac}} \qquad 18.32$$

If NPSHA is less than NPSHR, the fluid will cavitate. The criterion for cavitation is given by Eq. 18.33. (In practice, it is desirable to have a safety margin.)

$$\text{NPSHA} < \text{NPSHR} \quad \text{[criterion for cavitation]} \qquad 18.33$$



Example 18.8

2.0 ft^3/sec (56 L/s) of 60°F (16°C) water are pumped from an elevated feed tank to an open reservoir through 6 in (15.2 cm), schedule-40 steel pipe, as shown. The friction loss for the piping and fittings in the suction line is 2.6 ft (0.9 m). The friction loss for the piping and fittings in the discharge line is 13 ft (4.3 m). The atmospheric pressure is 14.7 psia (101 kPa). What is the NPSHA?

[17] If NPSHR (a head term) is multiplied by the fluid specific weight, it is known as the *net inlet pressure required*, NIPR. Similarly, NPSHA can be converted to NIPA.

[18] It is also possible to calculate NPSHR from other information, such as suction specific speed. However, this still depends on information provided by the manufacturer.

[19] The friction loss and the acceleration are both maximum values, but they do not occur in phase. Combining them is conservative.

SI Solution

The density of water is approximately 1000 kg/m^3. The atmospheric head is

$$h_{\text{atm}} = \frac{p}{\rho g} = \frac{(101 \text{ kPa})\left(1000 \frac{\text{Pa}}{\text{kPa}}\right)}{\left(1000 \frac{\text{kg}}{\text{m}^3}\right)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)}$$
$$= 10.3 \text{ m}$$

For 16°C water, the vapor pressure is approximately 0.01818 bars. The vapor pressure head is

$$h_{\text{vp}} = \frac{p}{\rho g} = \frac{(0.01818 \text{ bar})\left(1 \times 10^5 \frac{\text{Pa}}{\text{bar}}\right)}{\left(1000 \frac{\text{kg}}{\text{m}^3}\right)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)}$$
$$= 0.2 \text{ m}$$

From Eq. 18.30(a), the NPSHA is

$$\begin{aligned}\text{NPSHA} &= h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \\ &= 10.3 \text{ m} + 1.5 \text{ m} + 4.8 \text{ m} - 0.3 \text{ m} \\ &\quad - 0.9 \text{ m} - 0.2 \text{ m} \\ &= 15.2 \text{ m}\end{aligned}$$

Customary U.S. Solution

The specific weight of water is approximately 62.4 lbf/ft^3. The atmospheric head is

$$h_{\text{atm}} = \frac{p}{\gamma} = \frac{\left(14.7 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{62.4 \frac{\text{lbf}}{\text{ft}^3}}$$
$$= 33.9 \text{ ft}$$

For 60°F water, the vapor pressure is approximately 0.256 lbf/in^2. The vapor pressure head is

$$h_{\text{vp}} = \frac{p}{\gamma} = \frac{\left(0.256 \frac{\text{lbf}}{\text{in}^2}\right)\left(144 \frac{\text{in}^2}{\text{ft}^2}\right)}{62.4 \frac{\text{lbf}}{\text{ft}^3}}$$
$$= 0.6 \text{ ft}$$

From Eq. 18.30(a), the NPSHA is

$$\begin{aligned}\text{NPSHA} &= h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \\ &= 33.9 \text{ ft} + 5 \text{ ft} + 16 \text{ ft} - 1 \text{ ft} - 2.6 \text{ ft} - 0.6 \text{ ft} \\ &= 50.7 \text{ ft}\end{aligned}$$

18. PREVENTING CAVITATION

Cavitation is eliminated by increasing NPSHA or decreasing NPSHR. NPSHA can be increased by:

- increasing the height of the fluid source
- lowering the pump
- reducing friction and minor losses by shortening the suction line or using a larger pipe size
- reducing the temperature of the fluid at the pump entrance
- pressurizing the fluid supply tank
- reducing the flow rate or velocity (i.e., reducing the pump speed)

NPSHR can be reduced by:

- placing a throttling valve or restriction in the discharge line[20]
- using an oversized pump
- using a double-suction pump
- using an impeller with a larger eye
- using an inducer

High NPSHR applications, such as boiler feed pumps needing 150 to 250 ft (50 to 80 m), should use one or more booster pumps in front of each high-NPSHR pump. Such booster pumps are typically single-stage, double-suction pumps running at low speed. Their NPSHR can be 25 ft (8 m) or less.

Note that throttling the input line to a pump and venting or evacuating the receiving tank both increase cavitation. Throttling the input line increases the friction head and decreases NPSHA. Evacuating the receiving tank increases the flow rate, increasing NPSHR while simultaneously increasing the friction head and reducing NPSHA.

[20]This will increase the total head (h_A) added by the pump, thereby reducing the pump's output and driving the pump's operating point into a region of lower NPSHR.

19. CAVITATION COEFFICIENT

The *cavitation coefficient* (or *cavitation number*), σ, is a dimensionless number that can be used in modeling and extrapolating experimental results. The actual cavitation coefficient is compared with the critical cavitation number obtained experimentally. If the actual cavitation number is less than the critical cavitation number, cavitation will occur. Absolute pressure must be used in calculating σ.

$$\sigma = \frac{2(p - p_{vp})}{\rho v^2} = \frac{\text{NPSHA}}{h_A} \quad \text{[SI]} \qquad 18.34(a)$$

$$\sigma = \frac{2g_c(p - p_{vp})}{\rho v^2} = \frac{\text{NPSHA}}{h_A} \quad \text{[U.S.]} \qquad 18.34(b)$$

$$\sigma < \sigma_{cr} \quad \text{[criterion for cavitation]} \qquad 18.35$$

The two forms of Eq. 18.34 yield slightly different results. The first form is essentially the ratio of the net pressure available for collapsing a vapor bubble to the velocity pressure creating the vapor. It is useful in model experiments. The second form is applicable to tests of production model pumps.

20. SUCTION SPECIFIC SPEED

The formula for *suction specific speed*, n_{ss}, can be derived by substituting NPSHR for total head in the expression for specific speed. Q is halved for double-suction pumps.

$$n_{ss} = \frac{n\sqrt{\dot{V}}}{(\text{NPSHR in m})^{0.75}} \quad \text{[SI]} \qquad 18.36(a)$$

$$n_{ss} = \frac{n\sqrt{Q}}{(\text{NPSHR in ft})^{0.75}} \quad \text{[U.S.]} \qquad 18.36(b)$$

Suction specific speed is an index of the suction characteristics of the impeller. Ideally, it should be approximately 8500 (165 in SI) for both single- and double-suction pumps. This assumes the pump is operating at or near its point of optimum efficiency.

Suction specific speed can be used to determine the maximum recommended operating speed by substituting 8500 (165 in SI) for n_{ss} in Eq. 18.36 and solving for n.

If the suction specific speed is known, it can be used to determine the NPSHR. If the pump is known to be operating at or near its optimum efficiency, an approximate NPSHR value can be found by substituting 8500 (165 in SI) for n_{ss} in Eq. 18.36 and solving for NPSHR.

Suction specific speed available, SA, is obtained when NPSHA is substituted for total head in the expression for specific speed. The suction specific speed available must exceed the suction specific speed required to prevent cavitation.[21]

[21]Since speed and flow rate are constants, this is another way of saying NPSHA must equal or exceed NPSHR.

21. PUMP PERFORMANCE CURVES

For a given impeller diameter and constant speed, the head added will decrease as the flow rate increases. This can be shown graphically on the *pump performance curve (pump curve)* supplied by the pump manufacturer. Other operating characteristics (e.g., power requirement, NPSHR, and efficiency) also vary with flow rate, and these are usually plotted on a common graph, as shown in Fig. 18.10.[22] Manufacturers' pump curves show performance over a limited number of calibration speeds. If an operating point is outside the range of published curves, the affinity laws can be used to estimate the speed at which the pump gives the required performance.

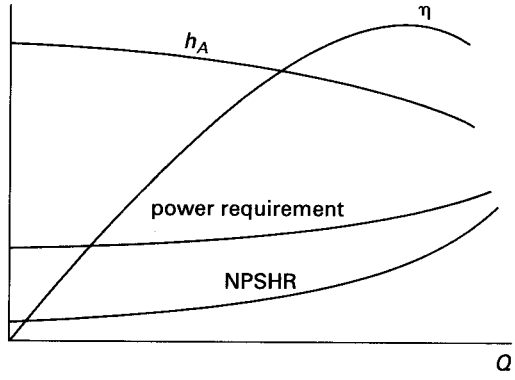


Figure 18.10 *Pump Performance Curves*

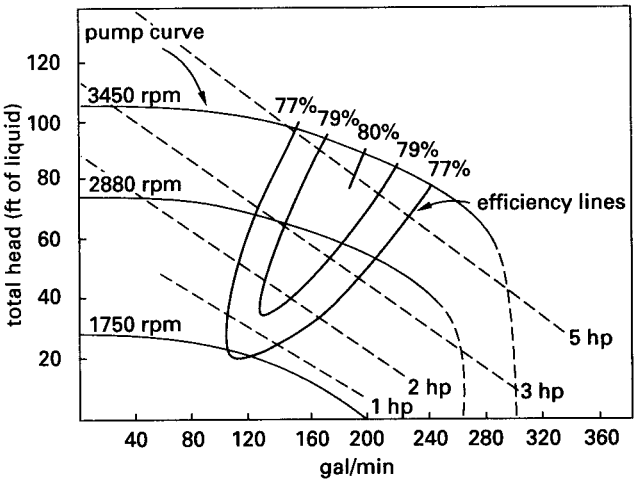
On the pump curve, the shutoff point (also known as churn) corresponds to a closed discharge valve (i.e., zero flow); the rated point is where the pump operates with rated (100corresponds to 65

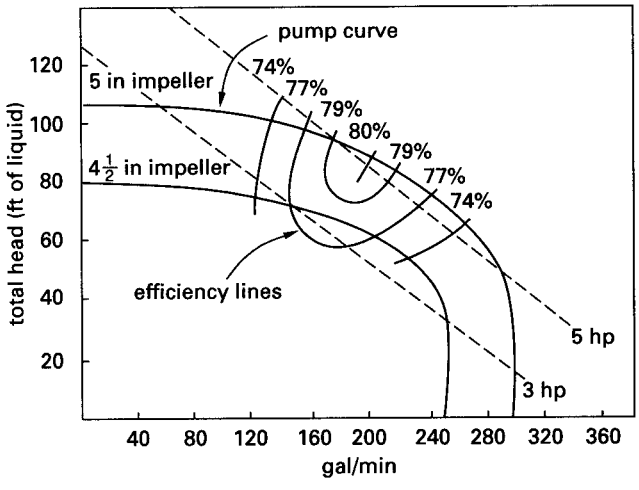
Figure 18.10 is for a pump with a fixed impeller diameter and rotational speed. The characteristics of a pump operated over a range of speed or for different impeller diameters are illustrated in Fig. 18.11.

22. SYSTEM CURVES



A *system curve* (or *system performance curve*) is a plot of the static and friction energy losses experienced by the fluid for different flow rates. Unlike the pump curve, which depends only on the pump, the system curve depends only on the configuration of the suction and discharge lines. (The following equations assume equal pressures at the fluid source and destination surfaces, which is the case for pumping from one atmospheric reservoir to another. The velocity head is insignificant and is disregarded.)

$$h_A = h_z + h_f \qquad 18.37$$



$$h_z = h_{z(d)} - h_{z(s)} \qquad 18.38$$

$$h_f = h_{f(s)} + h_{f(d)} \qquad 18.39$$

[22]The term *pump curve* is commonly used to designate the h_A versus Q characteristics, whereas *pump characteristics curve* implies all of the pump data.

(a) variable speed

(b) variable impeller diameter

Figure 18.11 *Centrifugal Pump Characteristics Curves*

If the fluid reservoirs are large, or if the fluid reservoir levels are continually replenished, the net static suction head ($h_{z(1)} - h_{z(2)}$) will be constant for all flow rates. The friction loss, h_f, varies with v^2 (and hence with Q) in the Darcy friction formula. This makes it easy to find friction losses for other flow rates once one friction loss is known.[23]

$$\frac{h_{f,1}}{h_{f,2}} = \left(\frac{Q_1}{Q_2}\right)^2 \qquad 18.40$$

Figure 18.12 illustrates a system curve with a positive static head. In the case of a negative static head (i.e., a fluid source above the fluid destination), the system curve would be depressed below the Q-axis and would cross it at some positive value of Q. Of course, the curve could also start at the origin.

[23]Equation 18.40 implicitly assumes that the friction factor, f, is constant. This may be true over a limited range of flow rates, but it is not true over large ranges unless the Hazen-Williams friction loss equation is being used. Nevertheless, Eq. 18.40 is often used to quickly construct preliminary versions of the system curve.

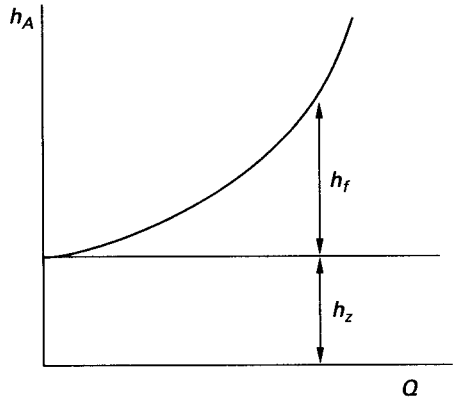


Figure 18.12 *System Curve*

23. OPERATING POINT

The intersection of the pump curve and the system curve determines the *operating point*, as shown in Fig. 18.13. The operating point defines the system head and system flow rate.

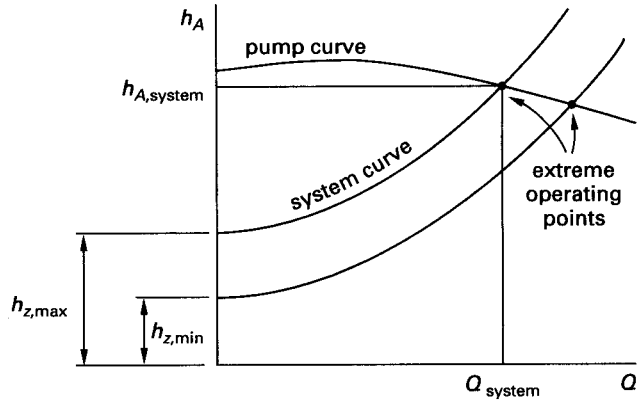

Figure 18.13 *Extreme Operating Points*

When selecting a pump, the system curve is plotted on manufacturers' pump curves for different speeds and/or impeller diameters (i.e., Fig. 18.11). There will be several possible operating points corresponding to the various pump curves shown. Generally, the design operating point should be close to the highest pump efficiency. This, in turn, will determine speed and impeller diameter.

In many systems, the static head will vary as the source reservoir is drained or as the destination reservoir fills. The system head is then defined by a pair of matching system friction curves intersecting the pump curve. The two intersection points are the *extreme operating points*—the maximum and minimum capacity requirements.

After a pump is installed, it may be desired to change the operating point. This can be done without replacing the pump by placing a throttling valve in the discharge

line. The operating point can then be moved along the pump curve by opening or closing the valve, as illustrated in Fig. 18.14. (A throttling valve should never be placed in the suction line since that would reduce NPSHA.)

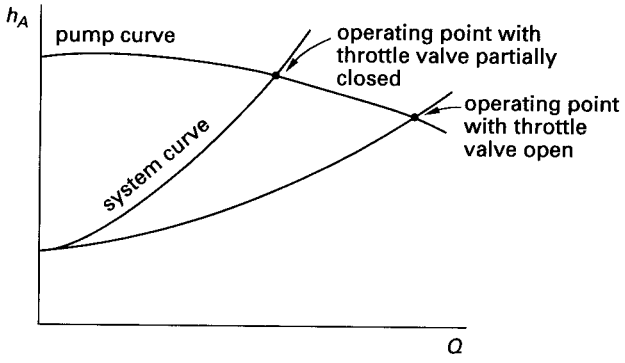

Figure 18.14 *Throttling the Discharge*

24. PUMPS IN PARALLEL

Parallel operation is obtained by having two pumps discharging into a common header. This type of connection is advantageous when the system demand varies greatly and when high reliability is required. A single pump providing total flow would have to operate far from its optimum efficiency at one point or another. With two pumps in parallel, one can be shut down during low demand. This allows the remaining pump to operate close to its optimum efficiency point.

Figure 18.15 illustrates that parallel operation increases the capacity of the system while maintaining the same total head.

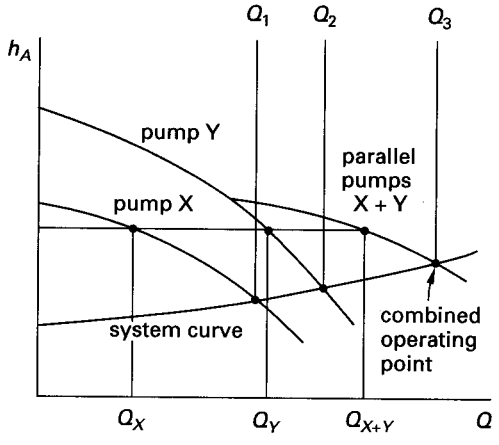

Figure 18.15 *Pumps Operating in Parallel*

The performance curve for a set of pumps in parallel can be plotted by adding the capacities of the two pumps at various heads. Capacity does not increase at heads above the maximum head of the smaller pump. Furthermore, a second pump will operate only when its discharge head is greater than the discharge head of the pump already running.

When the parallel performance curve is plotted with the system head curve, the operating point is the intersection of the system curve with the X + Y curve. With pump X operating alone, the capacity is given by Q_1. When pump Y is added, the capacity increases to Q_3 with a slight increase in total head.

25. PUMPS IN SERIES

Series operation is achieved by having one pump discharge into the suction of the next. This arrangement is used primarily to increase the discharge head, although a small increase in capacity also results.

The performance curve for a set of pumps in series can be plotted by adding the heads of the two pumps at various capacities.

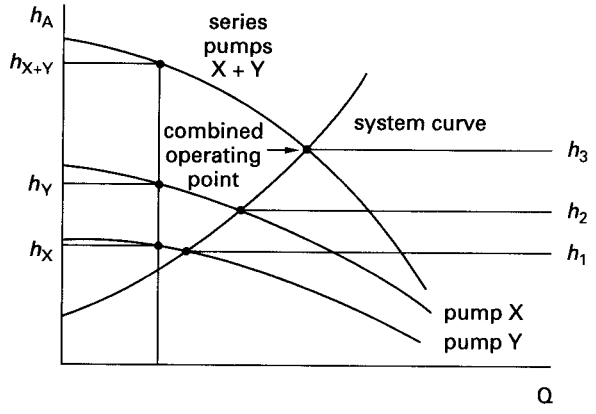

Figure 18.16 *Pumps Operating in Series*

26. AFFINITY LAWS

Most parameters (impeller diameter, speed, and flow rate) determining a pump's performance can vary. If the impeller diameter is held constant and the speed is varied, the following ratios are maintained with no change in efficiency.

$$\frac{Q_2}{Q_1} = \frac{n_2}{n_1} \qquad 18.41$$

$$\frac{h_2}{h_1} = \left(\frac{n_2}{n_1}\right)^2 = \left(\frac{Q_2}{Q_1}\right)^2 \qquad 18.42$$

$$\frac{P_2}{P_1} = \left(\frac{n_2}{n_1}\right)^3 = \left(\frac{Q_2}{Q_1}\right)^3 \qquad 18.43$$

If the speed is held constant and the impeller size is varied,

$$\frac{Q_2}{Q_1} = \frac{D_2}{D_1} \qquad 18.44$$

$$\frac{h_2}{h_1} = \left(\frac{D_2}{D_1}\right)^2 \qquad 18.45$$

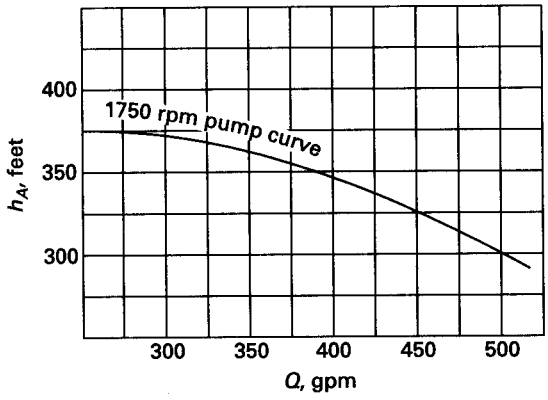
$$\frac{P_2}{P_1} = \left(\frac{D_2}{D_1}\right)^3 \qquad 18.46$$

The affinity laws are based on the assumption that the efficiencies of the two pumps are the same. In reality, larger pumps are somewhat more efficient than smaller pumps. Therefore, extrapolations to greatly different sized pumps should be avoided. Equation 18.47 can be used to estimate the efficiency of a different sized pump. The dimensionless exponent varies from 0 to approximately 0.26, with 0.2 being a typical value.

$$\frac{1-\eta_{\text{smaller}}}{1-\eta_{\text{larger}}} = \left(\frac{D_{\text{larger}}}{D_{\text{smaller}}}\right)^n \qquad 18.47$$

Example 18.9

A pump operating at 1770 rpm delivers 500 gal/min against a total head of 200 ft. Changes in the piping system have increased the total head to 375 ft. At what speed should this pump be operated to achieve this new head at the same efficiency?



Solution

From Eq. 18.42,

$$n_2 = n_1\sqrt{\frac{h_2}{h_1}} = 1770 \text{ rpm}\sqrt{\frac{375 \text{ ft}}{200 \text{ ft}}}$$
$$= 2424 \text{ rpm}$$

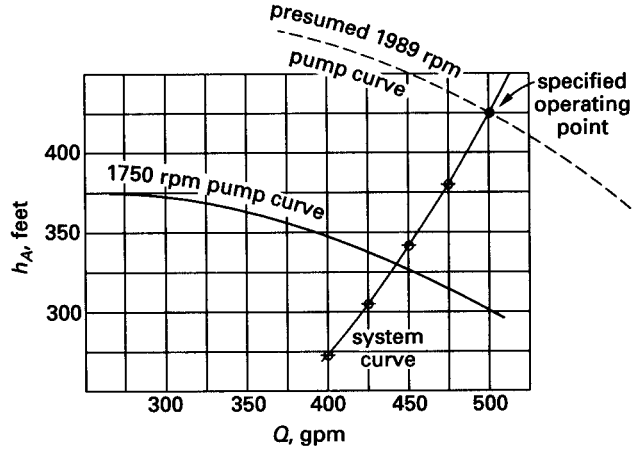
Example 18.10

A pump is required to pump 500 gal/min while providing a total dynamic head of 425 ft. The hydraulic system has no static head change. Only the 1750 rpm performance curve is known for the pump. At what speed must the pump be turned to achieve the desired performance with no change in efficiency or impeller size?

Solution

A flow of 500 gal/min with a head of 425 ft does not correspond to any point on the 1750 rpm curve.

From Eq. 18.42, the quantity h/Q^2 is constant.



$$\frac{h}{Q^2} = \frac{425 \text{ ft}}{\left(500 \frac{\text{gal}}{\text{min}}\right)^2} = 1.7 \times 10^{-3} \quad \text{[mixed units]}$$

In order to use the affinity laws, the operating point on the 1750 rpm curve must be determined. Random values of Q are chosen and the corresponding values of h are determined such that the ratio h/Q^2 is unchanged.

Q	h
475	383
450	344
425	307
400	272

These points are plotted and connected to draw the system curve. The intersection of the system and 1750 rpm pump curve at 440 gal/min defines the operating point at that speed. From Eq. 18.41,

$$n_2 = \frac{n_1 Q_2}{Q_1} = \frac{(1750 \text{ rpm})\left(500 \frac{\text{gal}}{\text{min}}\right)}{440 \frac{\text{gal}}{\text{min}}}$$
$$= 1989 \text{ rpm}$$

27. PUMP SIMILARITY

The performance of one pump can be used to predict the performance of a *dynamically similar (homologous) pump*. This can be done by using Eqs. 18.48 through 18.53.

$$\frac{n_1 D_1}{\sqrt{h_1}} = \frac{n_2 D_2}{\sqrt{h_2}} \qquad 18.48$$

$$\frac{Q_1}{D_1^2\sqrt{h_1}} = \frac{Q_2}{D_2^2\sqrt{h_2}} \qquad 18.49$$

$$\frac{P_1}{\rho_1 D_1^2 h_1^{1.5}} = \frac{P_2}{\rho_2 D_2^2 h_2^{1.5}} \qquad 18.50$$

$$\frac{Q_1}{n_1 D_1^3} = \frac{Q_2}{n_2 D_2^3} \qquad 18.51$$

$$\frac{P_1}{\rho_1 n_1^3 D_1^5} = \frac{P_2}{\rho_2 n_2^3 D_2^5} \qquad 18.52$$

$$\frac{n_1\sqrt{Q_1}}{(h_1)^{0.75}} = \frac{n_2\sqrt{Q_2}}{(h_2)^{0.75}} \qquad 18.53$$

These *similarity laws* assume that both pumps:

- operate in the turbulent region
- have the same pump efficiency
- operate at the same percentage of wide-open flow

Similar pumps also will have the same specific speed and cavitation number.

As with the affinity laws, these relationships assume that the efficiencies of the larger and smaller pumps are the same. In reality, larger pumps will be more efficient than smaller pumps. Therefore, extrapolations to much larger or much smaller sizes should be avoided.

Example 18.11

A 6 in pump operating at 1770 rpm discharges 1500 gal/min of cold water (SG = 1.0) against an 80 ft head at 85% efficiency. A homologous 8 in pump operating at 1170 rpm is being considered as a replacement. (a) What total head and capacity can be expected from the new pump? (b) What would be the new horsepower requirement?

Solution

(a) From Eq. 18.48,

$$h_2 = \left(\frac{D_2 n_2}{D_1 n_1}\right)^2 h_1 = \left(\frac{(8\text{ in})(1170\text{ rpm})}{(6\text{ in})(1770\text{ rpm})}\right)^2 (80\text{ ft})$$

$$= 62.14\text{ ft}$$

From Eq. 18.51,

$$Q_2 = \left(\frac{n_2 D_2^3}{n_1 D_1^3}\right) Q_1$$

$$= \left(\frac{(1170\text{ rpm})(8\text{ in})^3}{(1770\text{ rpm})(6\text{ in})^3}\right)\left(1500\ \frac{\text{gal}}{\text{min}}\right)$$

$$= 2350.3\text{ gal/min}$$

(b) From Table 18.5, the hydraulic horsepower is

$$\text{WHP}_2 = \frac{h_2 Q_2 (\text{SG})}{3956} = \frac{(62.14\text{ ft})\left(2350.3\ \frac{\text{gal}}{\text{min}}\right)(1.0)}{3956\ \frac{\text{ft-gal}}{\text{hp-min}}}$$

$$= 36.92\text{ hp}$$

From Eq. 18.47,

$$\eta_{\text{larger}} = 1 - \frac{1 - \eta_{\text{smaller}}}{\left(\frac{D_{\text{larger}}}{D_{\text{smaller}}}\right)^{0.2}}$$

$$= 1 - \frac{1 - 0.85}{\left(\frac{8\text{ in}}{6\text{ in}}\right)^{0.2}} = 0.858$$

$$\text{BHP}_2 = \frac{\text{WHP}_2}{\eta_p} = \frac{36.92\text{ hp}}{0.858} = 43.0\text{ hp}$$

28. PUMPING LIQUIDS OTHER THAN COLD WATER

Many pump parameters are determined from tests with cold, clear water at 85°F (29°C). The following guidelines can be used when pumping water at other temperatures or when pumping other fluids.

- Head developed is independent of the liquid's specific gravity. Pump performance curves from tests with water can be used with other Newtonian fluids (e.g., gasoline, alcohol, and aqueous solutions) having similar viscosities.
- Head, flow rate, and efficiency are all reduced when pumping highly viscous non-Newtonian fluids. No exact method exists for determining the reduction factors, other than actual tests of an installation using both fluids. Some sources have published charts of correction factors based on tests over limited viscosity and size ranges.[24]
- The hydraulic horsepower depends on the specific gravity of the fluid. If the pump characteristic curve is used to find the operating point, multiply the horsepower reading by the specific gravity. Tables 18.5 and 18.6 incorporate the specific gravity term in the calculation of hydraulic power where required.
- Efficiency is not affected by changes in temperature that cause only the specific gravity to change.
- Efficiency is nominally affected by changes in temperature that cause the viscosity to change. Equation 18.54 is an approximate relationship suggested by the Hydraulics Institute when extrapolating the efficiency (in decimal form) from cold water to hot water. n is an experimental exponent established by the pump manufacturer, generally in the range of 0.05 to 0.1.

$$\eta_{\text{hot}} = 1 - (1 - \eta_{\text{cold}})\left(\frac{\nu_{\text{hot}}}{\nu_{\text{cold}}}\right)^n \qquad 18.54$$

[24] A chart published by the Hydraulics Institute is widely distributed.

- NPSHR is not significantly affected by minor variations in the water temperature.
- When hydrocarbons are pumped, the NPSHR determined from cold water can usually be reduced. This reduction is apparently due to the slow vapor release of complex organic liquids. If the hydrocarbon's vapor pressure at the pumping temperature is known, Fig. 18.17 will give the percentage of the cold-water NPSHR.

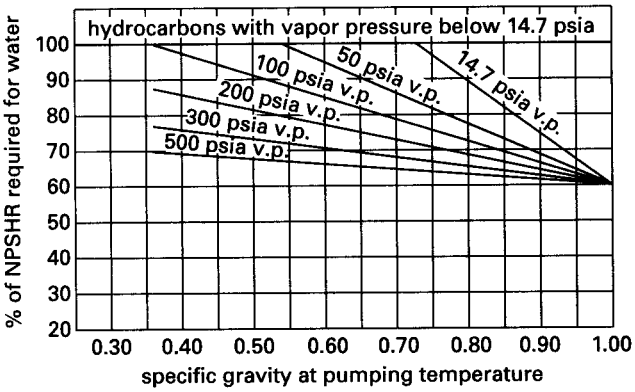


Figure 18.17 *Hydrocarbon NPSHR Correction Factor*

- Pumping many fluids requires expertise that goes far beyond simply extrapolating parameters in proportion to the fluid's specific gravity. Such special cases include pumping liquids containing abrasives, liquids that solidify, highly corrosive liquids, liquids with vapor or gas, highly viscous fluids, paper stock, and hazardous fluids.

Example 18.12

A centrifugal pump has an NIPR (NPSHR) of 12 psi based on cold water. 10°F isobutane has a specific gravity of 0.60 and a vapor pressure of 15 psia. What NPSHR should be used with 10°F liquid isobutane?

Solution

From Fig. 18.17, the intersection of a specific gravity of 0.60 and 15 psia is above the horizontal 100% line. The full NPSHR of 12 psi should be used.

29. TURBINE SPECIFIC SPEED

Like centrifugal pumps, turbines are classified according to the manner in which the impeller extracts energy from the fluid flow. This is measured by the turbine-specific speed equation, which is different from the equation used to calculate specific speed for pumps.

$$n_s = \frac{n\sqrt{P \text{ in kW}}}{(h_t)^{1.25}} \qquad \text{[SI]} \qquad \textit{18.55(a)}$$

$$n_s = \frac{n\sqrt{P \text{ in hp}}}{(h_t)^{1.25}} \qquad \text{[U.S.]} \qquad \textit{18.55(b)}$$

30. TYPES OF TURBINES

Each of the three types of turbines is associated with a range of specific speeds.

- Axial-flow turbines are used for low heads, high rotational speeds, and large flow rates. These propeller turbines operate with specific speeds in the 80 to 200 range (300 to 760 in SI). Their best efficiencies, however, are produced with specific speeds between 120 and 160 (460 and 610 in SI).
- For reaction turbines, the specific speed varies from 10 to 100 (38 and 380 in SI). Best efficiencies are found in the 40 to 60 (150 and 230 in SI) range with heads below 600 to 800 ft (180 to 240 m).
- Radial-flow (impulse) turbines have the lowest specific speeds but are used when heads are high. These turbines have specific speeds below 5 (19 in SI).

31. HYDROELECTRIC GENERATING PLANTS

In a typical hydroelectric generating plant using reaction turbines, the turbine is generally housed in a *powerhouse*, with water conducted to the turbine through the *penstock* piping. Water originates in a reservoir, dam, or *forebay* (in the instance where the reservoir is a long distance from the turbine).

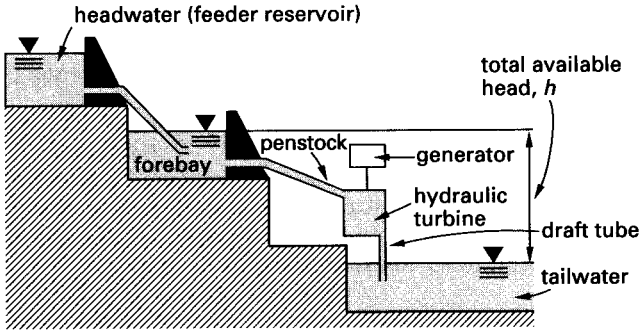

Figure 18.18 *Typical Hydroelectric Plant*

After the water passes through the turbine, it is discharged through the draft tube to the receiving reservoir, known as the *tailwater*. The *draft tube* is used to keep the turbine up to 15 ft (5 m) above the tailwater surface, while still being able to extract the total available head. If a draft tube is not employed, water may be returned to the tailwater by way of a channel known as the *tail race*. The turbine, draft tube, and all related parts comprise what is known as the *setting*.

When a forebay is not part of the generating plant's design, it will be desirable to provide a *surge chamber* in order to relieve the effects of rapid changes in flow rate. In the case of a sudden power demand, the surge chamber would provide an immediate source of water, without waiting for a contribution from the feeder reservoir.

Similarly, in the case of a sudden decrease in discharge through the turbine, the excess water would surge back into the surge chamber.

32. IMPULSE TURBINES

An *impulse turbine* consists of a rotating shaft (called a *turbine runner*) on which buckets or blades are mounted. (This is commonly called a *Pelton wheel.*)[25] A jet of water (or other fluid) hits the buckets and causes the turbine to rotate. The kinetic energy of the jet is converted into rotational kinetic energy. The jet is essentially at atmospheric pressure.

Impulse turbines are generally employed where the available head is very high, above 800 to 1600 ft (250 to 500 m). (There is no exact value for the critical head, hence the range. What is important is that impulse turbines are *high-head turbines.*) Efficiencies are in the range of 80 to 90%, with the higher efficiencies being associated with turbines having two or more jets per runner.

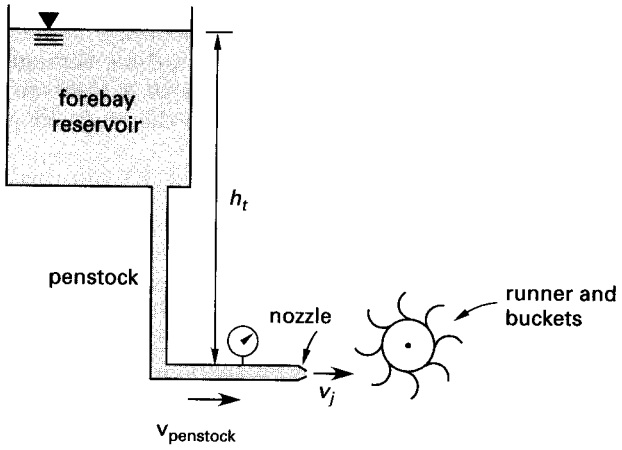

Figure 18.19 *Impulse Turbine Installation*

The total available head in this installation is h_t, but not all of this energy can be extracted. Some of the energy is lost to friction in the penstock. Minor losses also occur, but these small losses are usually disregarded. In the penstock, immediately before entering the nozzle, the remaining head is divided between the pressure head and the velocity head.[26]

$$h' = h_t - h_f = (h_p + h_v)_{\text{penstock}} \qquad 18.56$$

[25]In a Pelton wheel turbine, the spoon-shaped buckets are divided into two halves, with a ridge between the halves. Half of the water is thrown to each side of the bucket. A Pelton wheel is known as a *tangential turbine (tangential wheel)* because the centerline of the jet is directed at the centers of the buckets.

[26]Care must be taken to distinguish between the conditions existing in the penstock, the nozzle throat, and the jet itself. The velocity in the nozzle throat and jet will be the same, but this is different from the penstock velocity. Similarly, the pressure in the jet is zero, although it is nonzero in the penstock.

Another loss, h_n, occurs in the nozzle itself. The head remaining to turn the turbine is

$$\begin{aligned} h'' &= h' - h_n \\ &= h_t - h_f - h_n \end{aligned} \qquad 18.57$$

h_f is calculated from either the Darcy or the Hazen-Williams equation. The nozzle loss is calculated from the *nozzle coefficient*, C_v.

$$h_n = h'(1 - C_v^2) \qquad 18.58$$

The total head at the nozzle exit is converted into velocity head according to the Torricelli equation.

$$v_j = \sqrt{2gh''} = C_v\sqrt{2gh'} \qquad 18.59$$

In order to maximize power output, buckets are usually designed to partially reverse the direction of the water jet flow. The forces on the turbine buckets can be found from the impulse-momentum equations. If the water is turned through an angle θ and the wheel's *tangential velocity* is v_b, the energy transmitted by each unit mass of water to the turbine runner is[27]

$$E = v_b(v_j - v_b)(1 - \cos\theta) \quad \text{[SI]} \qquad 18.60(a)$$

$$E = \left[\frac{v_b(v_j - v_b)}{g_c}\right](1 - \cos\theta) \quad \text{[U.S.]} \qquad 18.60(b)$$

$$v_b = \frac{2\pi nr}{60} = \omega r \qquad 18.61$$

The theoretical *turbine power* is found by multiplying Eq. 18.60 by the mass flow rate. The actual power will be less than the theoretical output. Typical turbine efficiencies range between 80 and 90%. For a mass flow rate in kg/s, the theoretical power (in kilowatts) will be

$$P_{\text{th}} = \frac{\dot{m}E}{1000} \quad \text{[SI]} \qquad 18.62(a)$$

For a mass flow rate in lbm/sec, the theoretical horsepower will be

$$P_{\text{th}} = \frac{\dot{m}E}{550} \quad \text{[U.S.]} \qquad 18.62(b)$$

Example 18.13

A Pelton wheel impulse turbine develops 100 hp (brake) while turning at 500 rpm. The water is supplied from a penstock with an internal area of 0.3474 ft^2. The water subsequently enters a nozzle with a reduced flow area. The total head is 200 ft before nozzle loss. The turbine efficiency is 80%, and the nozzle coefficient, C_v, is 0.95. Disregard penstock friction losses. What are

[27]$\theta = 180°$ would be ideal. However, the actual angle is limited to approximately 165° to keep the deflected jet out of the way of the incoming jet.

the (a) flow rate (in ft^3/sec), (b) area of the jet, and (c) pressure head in the penstock just before the nozzle?

Solution

(a) From Eq. 18.59 with $h' = h_t = 200$ ft, the jet velocity is

$$v_j = C_v\sqrt{2gh'} = 0.95\sqrt{(2)\left(32.2\ \frac{ft}{sec^2}\right)(200\ ft)}$$
$$= 107.8\ ft/sec$$

From Eq. 18.58, the nozzle loss is

$$h_n = h'(1 - C_v^2) = (200\ ft)\left(1 - (0.95)^2\right)$$
$$= 19.5\ ft$$

From Table 18.5, the flow rate is

$$\dot{V} = \frac{(8.814)(P)}{h_A(SG)\eta} = \frac{(8.814)(100\ hp)}{(200\ ft - 19.5\ ft)(1)(0.8)}$$
$$= 6.104\ ft^3/sec$$

(b) The jet area is

$$A_j = \frac{\dot{V}}{v_j} = \frac{6.104\ \frac{ft^3}{sec}}{107.8\ \frac{ft}{sec}} = 0.0566\ ft^2$$

(c) The velocity in the penstock is

$$v_{penstock} = \frac{\dot{V}}{A} = \frac{6.104\ \frac{ft^3}{sec}}{0.3474\ ft^2}$$
$$= 17.57\ ft/sec$$

The pressure head in the penstock is

$$h_p = h' - h_v = h' - \frac{v^2}{2g}$$
$$= 200\ ft - \frac{\left(17.57\ \frac{ft}{sec}\right)^2}{(2)\left(32.2\ \frac{ft}{sec^2}\right)}$$
$$= 195.2\ ft$$

33. REACTION TURBINES

Reaction turbines (also known as *Francis turbines* or *radial-flow turbines*) are essentially centrifugal pumps operating in reverse. They are used when the total available head is small, typically below 600 to 800 ft. However, their energy conversion efficiency is higher than that of impulse turbines, typically in the 85 to 95% range.

In a reaction turbine, water enters the turbine housing with a pressure greater than atmospheric pressure. The water completely surrounds the turbine runner (impeller) and continues through the draft tube. There is no vacuum or air pocket between the turbine and the tailwater.

All of the power, affinity, and similarity relationships used with centrifugal pumps can be used with reaction turbines.

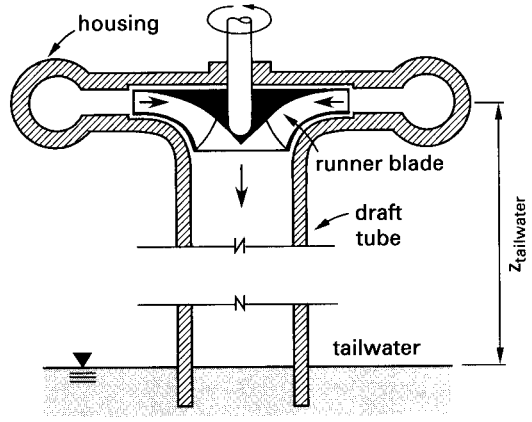

Figure 18.20 *Reaction Turbine*

Example 18.14

A reaction turbine with a draft tube develops 500 hp (brake) when 50 ft^3/sec of water flow through it. Water enters the turbine at 20 ft/sec with a 100 ft pressure head. The elevation of the turbine above the tailwater level is 10 ft. Disregarding friction, what are the (a) total available head and (b) turbine efficiency?

Solution

(a) The available head is the difference between the forebay and tailwater elevations. The tailwater depression is known, but the height of the forebay above the turbine is not known. At the turbine entrance, this unknown potential energy has been converted to pressure and velocity head. Therefore, the total available head (exclusive of friction) is

$$h_t = z_{forebay} - z_{tailwater}$$
$$= h_p + h_v - z_{tailwater}$$
$$= 100\ ft + \frac{\left(20\ \frac{ft}{sec}\right)^2}{(2)\left(32.2\ \frac{ft}{sec^2}\right)} - (-10\ ft)$$
$$= 116.2\ ft$$

(b) From Table 18.5, the theoretical hydraulic horsepower is

$$P_{\text{th}} = \frac{h_A \dot{V}(\text{SG})}{8.814} = \frac{(116.2 \text{ ft})\left(50 \frac{\text{ft}^3}{\text{sec}}\right)(1.0)}{8.814}$$
$$= 659.2 \text{ hp}$$

The efficiency of the turbine is

$$\eta = \frac{P_{\text{brake}}}{P_{\text{th}}} = \frac{500 \text{ hp}}{659.2 \text{ hp}} = 0.758 \quad (75.8\%)$$

34. AXIAL-FLOW TURBINES

Figure 18.21 illustrates an *axial-flow turbine*, also known as a *propeller turbine*. Analysis of performance is similar to that of reaction and impulse turbines.

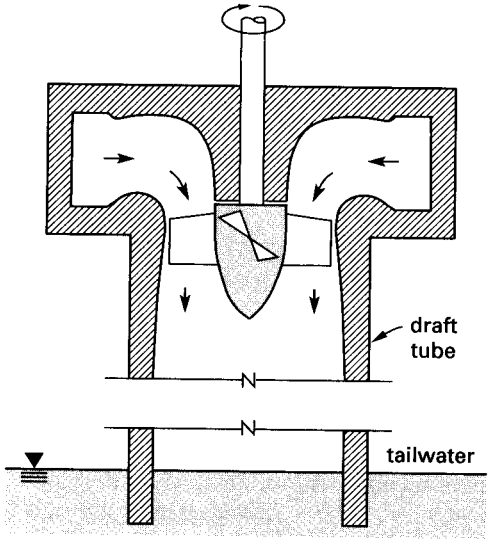

Figure 18.21 *Axial-Flow Turbine*

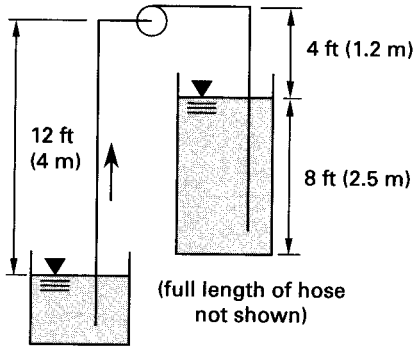
PRACTICE PROBLEMS

Pumping Power

1. 2000 gal/min of 60°F thickened sludge with a specific gravity of 1.2 flow through a pump with an inlet diameter of 12 in and an outlet of 8 in. The centerlines of the inlet and outlet are at the same elevation. The inlet pressure is 8 in of mercury (vacuum). A discharge pressure gauge located 4 ft above the pump discharge centerline reads 20 psig. The pump efficiency is 85%. All pipes are schedule-40. What is the input power of the pump?

(A) 26 hp
(B) 31 hp
(C) 37 hp
(D) 53 hp



The answer is (C).

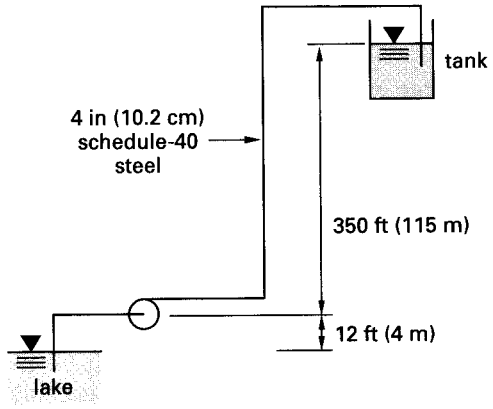
2. 1.25 ft^3/sec (35 L/s) of 70°F (21°C) water are pumped from the bottom of a tank through 700 ft (230 m) of 4 in (10.2 cm) schedule-40 steel pipe. The line includes a 50 ft (15 m) rise in elevation, two right-angle elbows, a wide-open gate valve, and a swing check valve. All fittings and valves are regular screwed. The inlet pressure is 50 psig (345 kPa), and a working pressure of 20 psig (140 kPa) is needed at the end of the pipe. What is the hydraulic power for this pumping application?

(A) 16 hp (13 kW)
(B) 23 hp (17 kW)
(C) 49 hp (37 kW)
(D) 66 hp (50 kW)

The answer is (A).

3. 80 gal/min (5 L/s) of 80°F (27°C) water are lifted 12 ft (4 m) vertically by a pump through 50 ft (15 m) of a 2 in (5.1 cm) diameter rubber hose. The discharge end of the hose is submerged in 8 ft (2.5 m) of water as shown. What head is added by the pump?

(A) 10 ft (3.0 m)
(B) 13 ft (4.3 m)
(C) 22 ft (6.6 m)
(D) 31 ft (9.3 m)



The answer is (B).

4. A 20 hp motor drives a centrifugal pump. The pump discharges 60°F (16°C) water at 12 ft/sec (4 m/s) into a 6 in (15.2 cm) steel schedule-40 line. The inlet is 8 in (20.3 cm) schedule-40 steel pipe. The pump suction is 5 psi (35 kPa) below standard atmospheric pressure. The friction head loss in the system is 10 ft (3.3 m). The pump efficiency is 70%. The suction and discharge lines are at the same elevation. What is the maximum height above the pump inlet that water is available at standard atmospheric pressure?

(A) 28 ft (6.9 m)
(B) 37 ft (11 m)
(C) 49 ft (15 m)
(D) 81 ft (25 m)

The answer is (A).

5. (*Time limit: one hour*) A pump station is used to fill a tank on a hill above from a lake below. The flow rate is 10,000 gal/hr (10.5 L/s) of 60°F (16°C) water. The atmospheric pressure is 14.7 psia (101 kPa). The pump is 12 ft (4 m) above the lake, and the tank surface level is 350 ft (115 m) above the pump. The suction and discharge lines are 4 in (10.2 cm) diameter schedule-40 steel pipe. The equivalent length of the inlet line between the lake and the pump is 300 ft (100 m). The total equivalent length between the lake and the tank is 7000 ft (2300 m), including all fittings, bends, screens, and valves. The cost of electricity is $0.04 per kW-hr. The overall efficiency of the pump and motor set is 70%.

(a) What does it cost to operate the pump for 1 hr?

(A) $0.1
(B) $1
(C) $3
(D) $6

The answer is (B).

(b) What motor power is required?

(A) 10 hp (7.5 kW)
(B) 30 hp (25 kW)
(C) 50 hp (40 kW)
(D) 75 hp (60 kW)

The answer is (B).

(c) What is the NPSHA for this application?

(A) 4 ft (1.2 m)
(B) 8 ft (2.4 m)
(C) 12 ft (3.6 m)
(D) 16 ft (4.5 m)

The answer is (D).

6. (*Time limit: one hour*) A town with a stable, constant population of 10,000 produces sewage at the average rate of 100 gallons per capita day (gpcd), with peak flows of 250 gpcd. The pipe to the pumping station is 5000 ft in length and has a C-value of 130. The elevation drop along the length is 48 ft. Minor losses in infiltration are insignificant. The pump's maximum suction lift is 10 ft.

(a) If all diameters are available, what pipe diameter is required?

(A) 8 in
(B) 12 in
(C) 14 in
(D) 18 in

The answer is (B).

(b) If constant-speed pumps are used, what is the minimum number of pumps (disregarding spares and backups) that should be used?

(A) 2
(B) 3
(C) 4
(D) 5

The answer is (B).

(c) If variable-speed pumps are used, what is the minimum number of pumps (disregarding spares and backups) that should be used?

(A) 1
(B) 2
(C) 3
(D) 4

The answer is (B).

(d) If three constant-speed pumps are used, what motor power is required?

(A) 2 hp
(B) 5 hp
(C) 8 hp
(D) 12 hp

The answer is (A).

(e) If two variable-speed pumps are used, what motor power is required?

(A) 3 hp
(B) 8 hp
(C) 12 hp
(D) 18 hp

The answer is (A).

(f) Which of the following are NOT all ways of controlling variable-speed pumps?

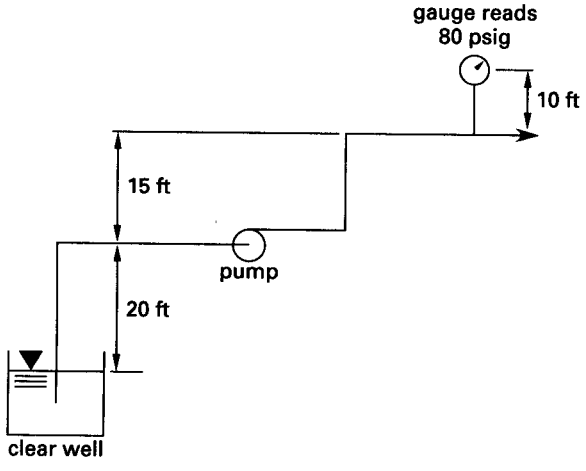
I. detecting sump levels
II. detecting pressure changes in the sump
III. detecting incoming flow rates
IV. using fixed run times
V. detecting outgoing flow rates
VI. operating manually

(A) I, II, and III
(B) I, IV, and V
(C) I, III, and V
(D) I, V, and VI

The answer is (B).

(g) With intermittent fan operation, approximately how many air changes should the wet well receive per hour?

(A) 6
(B) 12
(C) 20
(D) 30



The answer is (D).

(h) With continuous fan operation, approximately how many air changes should the dry well receive per hour?

(A) 6
(B) 12
(C) 20
(D) 30

The answer is (A).

7. (*Time limit: one hour*) A pump transfers 3.5 MGD of filtered water from the clear well of a 10 ft by 20 ft (plan) rapid sand filter to a higher elevation. The pump efficiency is 85%, and the motor driving pump has an efficiency of 90%. Minor losses are insignificant. Refer to the following illustration for additional information.

(a) What is the static suction lift?

(A) 15 ft
(B) 20 ft
(C) 35 ft
(D) 40 ft

The answer is (B).

(b) What is the static discharge head?

(A) 15 ft
(B) 20 ft
(C) 35 ft
(D) 40 ft

The answer is (A).

(c) Based on the information given, what is the approximate total dynamic head?

(A) 45 ft
(B) 185 ft
(C) 210 ft
(D) 230 ft

The answer is (D).

(d) What motor power is required?

(A) 50 hp
(B) 100 hp
(C) 150 hp
(D) 200 hp

The answer is (D).

(e) If the filter output is increased by 25%, how much surplus will accumulate in 8 hr?

(A) 60,000 gal
(B) 180,000 gal
(C) 250,000 gal
(D) 370,000 gal

The answer is (A).

Pumping Other Fluids

8. (*Time limit: one hour*) Gasoline with a specific gravity of 0.7 and viscosity of 6×10^{-6} ft^2/sec (5.6×10^{-7} m^2/s) is transferred from a tanker to a storage tank. The interior of the storage tank is maintained at atmospheric pressure by a vapor-recovery system. The free surface in the storage tank is 60 ft (20 m) above the tanker's free surface. The pipe consists of 500 ft (170 m) of 3 in (7.62 cm) schedule-40 steel pipe with six flanged elbows and two wide-open gate valves. The pump and motor both have individual efficiencies of 88%. Electricity costs $0.045 per kW-hr. The pump's performance data (based on cold, clear water) are known.

flow rate gpm (L/s)	head ft (m)
0 (0)	127 (42)
100 (6.3)	124 (41)
200 (12)	117 (39)
300 (18)	108 (36)
400 (24)	96 (32)
500 (30)	80 (27)
600 (36)	55 (18)

(a) What is the transfer rate?

(A) 150 gal/min (9.2 L/s)
(B) 180 gal/min (11 L/s)
(C) 200 gal/min (12 L/s)
(D) 230 gal/min (14 L/s)

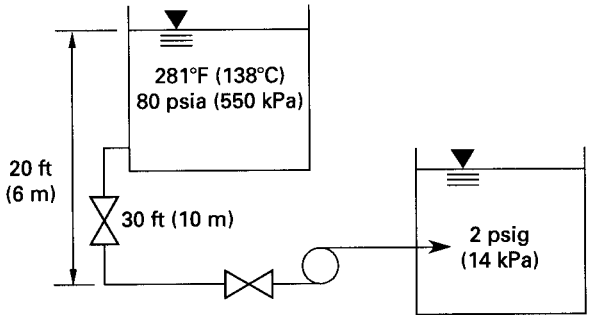
The answer is (D).

(b) What is the total cost of operating the pump for 1 hr?

(A) $0.20
(B) $0.80
(C) $1.30
(D) $2.70

The answer is (A).

Specific Speed



9. A double-suction water pump moving 300 gal/sec (1.1 kL/s) turns at 900 rpm. The pump adds 20 ft (7 m) of head to the water. What is the specific speed?

(A) 3000 rpm (52 rpm)
(B) 6000 rpm (100 rpm)
(C) 9000 rpm (160 rpm)
(D) 12,000 rpm (210 rpm)

The answer is (C).

Cavitation

10. 100 gal/min (6.3 L/s) of pressurized hot water at 281°F and 80 psia (138°C and 550 kPa) is drawn through 30 ft (10 m) of 1.5 in (3.81 cm) schedule-40 steel pipe into a 2 psig (14 kPa) tank. The inlet and outlet are both 20 ft (6 m) below the surface of the water when the tank is full. The inlet line contains two wide-open gate valves and two long-radius elbows. All components are regular screwed. The pump's NPSHR is 10 ft (3 m) for this application. The kinematic viscosity of 281°F (138°C) water is 0.239×10^{-5} ft^2/sec (0.222×10^{-6} m^2/s) and the vapor pressure is 50.02 psia (3.431 bar). Will the pump cavitate?

(A) yes; NPSHA = 4 ft (1.2 m)
(B) yes; NPSHA = 9 ft (2.7 m)
(C) no; NPSHA = 24 ft (7.2 m)
(D) no; NPSHA = 68 ft (21 m)

The answer is (D).

11. The velocity of the tip of a marine propeller is 4.2 times the boat velocity. The propeller is located 8 ft (3 m) below the surface. The temperature of the seawater is 68°F (20°C). The density is approximately 64.0 lbm/ft^3 (1024 kg/m^3), and the salt content is 2.5% by weight. What is the practical maximum boat velocity, as limited strictly by cavitation?

(A) 9.1 ft/sec (2.7 m/s)
(B) 12 ft/sec (3.8 m/s)
(C) 15 ft/sec (4.5 m/s)
(D) 22 ft/sec (6.6 m/s)

The answer is (B).

Pump and System Curves

12. The inlet of a centrifugal water pump is 7 ft (2.3 m) above the free surface from which it draws. The inlet consists of 12 ft (4 m) of 2 in (5.08 cm) schedule-40 steel pipe and contains one long-radius elbow and one check valve. The discharge line is 2 in (5.08 cm) schedule-40 steel pipe and includes two long-radius elbows and an 80 ft (27 m) run. The discharge is 20 ft (6.3 m) above the free surface. All components are regular screwed. The water temperature is 70°F (21°C). The following pump curve data are applicable.

flow rate gpm (L/s)	head ft (m)
0 (0)	110 (37)
10 (0.6)	108 (36)
20 (1.2)	105 (35)
30 (1.8)	102 (34)
40 (2.4)	98 (33)
50 (3.2)	93 (31)
60 (3.6)	87 (29)
70 (4.4)	79 (26)
80 (4.8)	66 (22)
90 (5.7)	50 (17)

(a) What is the flow rate?

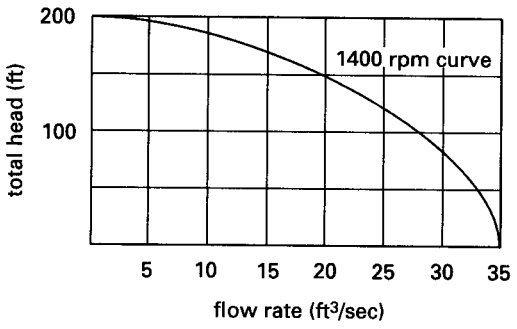
(A) 44 gal/min (2.9 L/s)
(B) 69 gal/min (4.5 L/s)
(C) 82 gal/min (5.5 L/s)
(D) 95 gal/min (6.2 L/s)

The answer is (D).

(b) What can be said about the use of this pump in this installation?

(A) A different pump should be used.
(B) The pump is operating near its most efficient point.
(C) Pressure fluctuations could result from surging.
(D) Overloading will not be a problem.

The answer is (A).



Affinity Laws

13. A pump was intended to run at 1750 rpm when driven by a 0.5 hp (0.37 kW) motor. What is the required power rating of a motor that will turn the pump at 2000 rpm?

(A) 0.25 hp (0.19 kW)
(B) 0.45 hp (0.34 kW)
(C) 0.65 hp (0.49 kW)
(D) 0.75 hp (0.55 kW)

The answer is (D).

14. (*Time limit: one hour*) A centrifugal pump running at 1400 rpm has the curve shown. The pump will be installed in an existing pipeline with known head requirements given by the formula $H = 30 + 2Q^2$. H is the system head in feet of water. Q is the flow rate in ft^3/sec.

(a) What is the flow rate if the pump is turned at 1400 rpm?
(A) 2000 gal/min
(B) 3500 gal/min
(C) 4000 gal/min
(D) 4500 gal/min

The answer is (C).

(b) What power is required to drive the pump?
(A) 190 hp
(B) 210 hp
(C) 230 hp
(D) 260 hp

The answer is (C).

(c) What is the flow rate if the pump is turned at 1200 rpm?
(A) 2000 gal/min
(B) 3500 gal/min
(C) 4000 gal/min
(D) 4500 gal/min

The answer is (B).

Turbines

15. A horizontal turbine reduces 100 ft^3/sec of water from 30 psia to 5 psia. Friction is negligible. What power is developed?
(A) 350 hp
(B) 500 hp
(C) 650 hp
(D) 800 hp

The answer is (C).

16. 1000 ft^3/sec of 60°F water flow from a high reservoir through a hydroelectric turbine installation, exiting 625 ft lower. The head loss due to friction is 58 ft. The turbine efficiency is 89%. What power is developed in the turbines?
(A) 40 kW
(B) 18 MW
(C) 43 MW
(D) 71 MW

The answer is (C).

17. Water at 500 psig and 60°F (3.5 MPa and 16°C) drives a 250 hp (185 kW) turbine at 1750 rpm against a back pressure of 30 psig (210 kPa). The water discharges through a 4 in (100 mm) diameter nozzle at 35 ft/sec (10.5 m/s). The water is deflected 80° by a single blade moving directly away at 10 ft/sec (3 m/s).

(a) What type of turbine is appropriate for this application?
(A) impulse turbine
(B) low-head turbine
(C) reaction turbine
(D) radial-flow turbine

The answer is (A).

(b) What is the total force acting on the blade?
(A) 100 lbf (450 N)
(B) 140 lbf (570 N)
(C) 160 lbf (720 N)
(D) 280 lbf (1300 N)

The answer is (B).

18. (*Time limit: one hour*) A Francis-design hydraulic reaction turbine with 22 in (560 mm) diameter blades runs at 610 rpm. The turbine develops 250 hp (185 kW) when 25 ft^3/sec (700 L/s) of water flow through it. The pressure head at the turbine entrance is 92.5 ft (30.8 m). The elevation of the turbine above the tailwater level is 5.26 ft (1.75 m). The inlet and outlet velocity are both 12 ft/sec (3.6 m/s).

(a) What is the effective head?

(A) 90 ft (30 m)
(B) 95 ft (31 m)
(C) 100 ft (33 m)
(D) 105 ft (35 m)

The answer is (C).

(b) What is the overall turbine efficiency?

(A) 81%
(B) 88%
(C) 93%
(D) 96%

The answer is B (U.S.); A (SI).

(c) What will be the turbine speed if the effective head is 225 ft (75 m)?

(A) 600 rpm
(B) 920 rpm
(C) 1100 rpm
(D) 1400 rpm

The answer is (B).

(d) What horsepower is developed if the effective head is 225 ft (75 m)?

(A) 560 hp (420 kW)
(B) 630 hp (470 kW)
(C) 750 hp (560 kW)
(D) 840 hp (630 kW)

The answer is (D).

(e) What is the flow rate if the effective head is 225 ft (75 m)?

(A) 25 ft^3/sec (700 L/s)
(B) 38 ft^3/sec (1100 L/s)
(C) 56 ft^3/sec (1600 L/s)
(D) 64 ft^3/sec (1800 L/s)

The answer is (B).

1. INTRODUCTION

An *open channel* is a fluid passageway that allows part of the fluid to be exposed to the atmosphere. This type of channel includes natural waterways, canals, culverts, flumes, and pipes flowing under the influence of gravity (as opposed to pressure conduits, which always flow full). A *reach* is a straight section of open channel with uniform shape, depth, slope, and flow quantity.

There are difficulties in evaluating open channel flow. The unlimited geometric cross sections and variations in roughness have contributed to a relatively small number of scientific observations upon which to estimate the required coefficients and exponents. Therefore, the analysis of open channel flow is more empirical and less exact than that of pressure conduit flow. This lack of precision, however, is more than offset by the percentage error in runoff calculations that generally precede the channel calculations.

Flow can be categorized on the basis of the channel material, for example, concrete or metal pipe or earth material. Except for a short discussion of erodible canals in Sec. 36, this chapter assumes the channel is nonerodible.

2. TYPES OF FLOW

Flow in open channels is almost always turbulent; laminar flow will occur only in very shallow channels or at very low fluid velocities. However, within the turbulent category are many somewhat confusing categories of flow. Flow can be a function of time and location. If the flow quantity (volume per unit of time across an area in flow) is invariant, it is said to be *steady flow.* (Flow that varies with time is virtually nonexistent.) If the flow cross section does not depend on the location along the channel, it is said to be *uniform flow.* Steady flow can also be *nonuniform flow*, as in the case of a river with a varying cross section or on a steep slope. Furthermore, uniform channel construction does not ensure uniform flow, as will be seen in the case of hydraulic jumps.

Table 19.1 summarizes some of the more common categories and names of steady open channel flow. All of the subcategories are based on variations in depth and flow area with respect to location along the channel.

Table 19.1 *Categories of Steady Open Channel Flow*

subcritical flow (tranquil flow)
- uniform flow (steady flow)
  - normal flow
- nonuniform flow (varied flow)
  - accelerating flow
  - decelerating flow (retarded flow)

critical flow

supercritical flow (rapid flow, shooting flow)
- uniform flow
  - normal flow
- nonuniform flow
  - accelerating flow
  - decelerating flow

3. MINIMUM VELOCITIES

The minimum permissible velocity in a sewer or other nonerodible channel is the lowest that prevents sedimentation and plant growth. Velocities of 2 to 3 ft/sec (0.6 to 0.9 m/s) keep all but the heaviest silts in suspension. 2.5 ft/sec (0.75 m/s) is considered the minimum to prevent plant growth.

4. VELOCITY DISTRIBUTION

Due to the adhesion between the wetted surface of the channel and the water, the velocity will not be uniform across the area in flow. The velocity term used in this chapter is the *mean velocity*. The mean velocity, when multiplied by the flow area, gives the flow quantity.

$$Q = Av \qquad 19.1$$

The location of the mean velocity depends on the distribution of velocities in the waterway, which is generally quite complex. The procedure for measuring the velocity of a channel (called *stream gauging*) involves measuring the average channel velocity at multiple locations across the channel width. These subaverage velocities are then themselves averaged to give a grand average (mean) flow velocity.

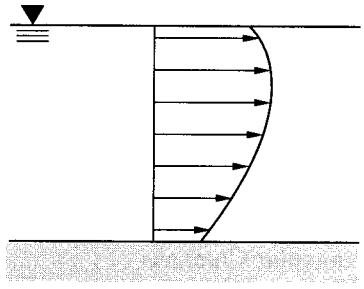

Figure 19.1 *Velocity Distribution in an Open Channel*

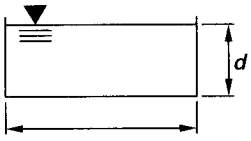
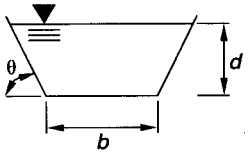
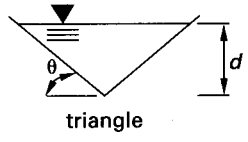
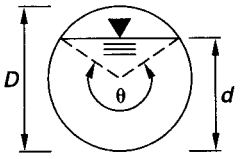
5. PARAMETERS USED IN OPEN CHANNEL FLOW









The *hydraulic radius* is the ratio of the area in flow to the wetted perimeter.[1]

$$R = \frac{A}{P} \qquad 19.2$$

For a circular channel flowing either full or half-full, the hydraulic radius is one-fourth of the equivalent diameter, $D_e/4$. The hydraulic radii of other channel shapes are easily calculated from the basic definition. Table 19.2 summarizes parameters for the basic shapes. For very wide channels such as rivers, the hydraulic radius is approximately equal to the depth.

[1]The hydraulic radius is also referred to as the *hydraulic mean depth.* However, this name is easily confused with "mean depth" and "hydraulic depth," both of which have different meanings. Therefore, the term "hydraulic mean depth" is not used in this chapter.

Table 19.2 *Hydraulic Parameters of Basic Channel Sections*

section	area, A	wetted perimeter, P	hydraulic radius, R
 rectangle	dw	$2d + w$	$\frac{dw}{w + 2d}$
 trapezoid	$\left(b + \frac{d}{\tan\theta}\right) d$	$b + 2\left(\frac{d}{\sin\theta}\right)$	$\frac{bd\sin\theta + d^2\cos\theta}{b\sin\theta + 2d}$
 triangle	$\frac{d^2}{\tan\theta}$	$\frac{2d}{\sin\theta}$	$\frac{d\cos\theta}{2}$
 circle	$\frac{1}{8}(\theta - \sin\theta)D^2$ [θ in radians]	$\frac{1}{2}\theta D$ [θ in radians]	$\frac{1}{4}\left(1 - \frac{\sin\theta}{\theta}\right) D$ [θ in radians]

The *hydraulic depth* is the ratio of the area in flow to the width of the channel at the fluid surface.[2]

$$D_h = \frac{A}{w} \qquad 19.3$$

The uniform flow *section factor* represents a frequently occurring variable group. The section factor is often evaluated against depth of flow when working with discharge from irregular cross sections.

$$\text{section factor} = AR^{\frac{2}{3}} \quad \text{[uniform flow]} \qquad 19.4$$

$$\text{section factor} = A\sqrt{D_h} \quad \text{[critical flow]} \qquad 19.5$$

The *slope*, S, is the slope of the energy line. In general, the slope can be calculated from the Bernoulli equation as the energy loss per unit length of channel. For small slopes typical of almost all natural waterways, the channel length and horizontal run are essentially identical.

[2]For a rectangular channel, $D_h = d$.

$$S = \frac{dE}{dL} \qquad 19.6$$

If the flow is uniform, the slope of the energy line will parallel the water surface and channel bottom, and the *energy gradient* will equal the *geometric slope*, S_0.

$$S_0 = \frac{\Delta z}{L} \quad \text{[uniform flow]} \qquad 19.7$$

Any open channel performance equation can be written using the geometric slope, S_0, instead of the hydraulic slope, S, but only under the condition of uniform flow.

In most problems, the slope is a function of the terrain and is known. However, it may be necessary to calculate the slope that results in some other specific parameter. The slope that produces flow at some normal depth, d, is called the *normal slope*. The slope that produces flow at some critical depth, d_c, is called the *critical slope*. Both are determined by solving the Manning equation for slope.

6. GOVERNING EQUATIONS FOR UNIFORM FLOW

Since water is incompressible, the continuity equation is

$$A_1 v_1 = A_2 v_2 \qquad 19.8$$

The most common equation used to calculate the flow velocity in open channels is the 1768 *Chezy equation.*[3]

$$v = C\sqrt{RS} \qquad 19.9$$

Various methods for evaluating the *Chezy coefficient*, C, or "Chezy's C," have been proposed.[4] If the channel is small and very smooth, Chezy's own formula can be used. The friction factor, f, is dependent on the Reynolds number and can be found in the usual manner from the Moody diagram.

$$C = \sqrt{\frac{8g}{f}} \qquad 19.10$$

If the channel is large and the flow is fully turbulent, then the friction loss will not depend so much on the Reynolds number as on the channel roughness. The 1888 Manning formula is frequently used to evaluate the constant C.[5] Notice that the value of C depends only on the channel roughness and geometry. (The conversion constant 1.49 in Eq. 19.11(b) is reported as 1.486 by some authorities. 1.486 is the correct SI-to-English conversion, but it is doubtful whether this equation warrants four significant digits.)

$$C = \left(\frac{1.00}{n}\right) R^{\frac{1}{6}} \qquad \text{[SI]} \qquad 19.11(a)$$

$$C = \left(\frac{1.49}{n}\right) R^{\frac{1}{6}} \qquad \text{[U.S.]} \qquad 19.11(b)$$

n is the *Manning roughness coefficient* (*Manning constant*). Typical values of Manning's n are given in App. 19.A. Judgment is needed in selecting values since tabulated values often differ by as much as 30%. More important to recognize for sewer work is the layer of slime that often coats the sewer walls. Since the slime characteristics can change with location in the sewer, there can be variations in Manning's roughness coefficient along the sewer length.

Independent of these factors, the value of n also depends on the depth of flow, leading to a value (n_{full}) specifically intended for use with full flow. (It is seldom clear from tabulations such as App. 19.A whether the values are for full flow or general use.) The variation in n can be taken into consideration using *Camp's correction*, shown in App. 19.C. However, this degree of sophistication cannot be incorporated into an analysis problem unless a specific value of n is known for a specific depth of flow.

Combining Eqs. 19.9 and 19.11 produces the *Manning equation*, also known as the *Chezy-Manning equation.*

$$v = \left(\frac{1.00}{n}\right) R^{\frac{2}{3}}\sqrt{S} \qquad \text{[SI]} \qquad 19.12(a)$$

$$v = \left(\frac{1.49}{n}\right) R^{\frac{2}{3}}\sqrt{S} \qquad \text{[U.S.]} \qquad 19.12(b)$$

All of the coefficients and constants in the Manning equation may be combined into the *conveyance*, K.

$$Q = vA = \left(\frac{1.00}{n}\right) AR^{\frac{2}{3}}\sqrt{S} = K\sqrt{S} \qquad \text{[SI]} \qquad 19.13(a)$$

$$Q = vA = \left(\frac{1.49}{n}\right) AR^{\frac{2}{3}}\sqrt{S} = K\sqrt{S} \qquad \text{[U.S.]} \qquad 19.13(b)$$

Example 19.1

A rectangular channel on a 0.002 slope is constructed of finished concrete. The channel is 8 ft (2.4 m) wide. Water flows at a depth of 5 ft (1.5 m). What is the flow rate?

SI Solution

The hydraulic radius is

$$R = \frac{A}{P} = \frac{(2.4\text{ m})(1.5\text{ m})}{1.5\text{ m} + 2.4\text{ m} + 1.5\text{ m}} = 0.67\text{ m}$$

From App. 19.A, the roughness coefficient for finished concrete is 0.012. The Manning coefficient is determined by Eq. 19.11(a).

$$C = \left(\frac{1.00}{n}\right) R^{\frac{1}{6}} = \left(\frac{1.00}{0.012}\right)(0.67\text{ m})^{\frac{1}{6}} = 77.9$$

The discharge is

$$Q = vA = C\sqrt{RS}A = \left(77.9\ \frac{\sqrt{\text{m}}}{\text{s}}\right)\left(\sqrt{(0.67\text{ m})(0.002)}\right)(1.5\text{ m})(2.4\text{ m}) = 10.3\text{ m}^3/\text{s}$$

Customary U.S. Solution

The hydraulic radius is

$$R = \frac{A}{P} = \frac{(8\text{ ft})(5\text{ ft})}{5\text{ ft} + 8\text{ ft} + 5\text{ ft}} = 2.22\text{ ft}$$

[3]Pronounced "Shay'-zee." This equation does not appear to be dimensionally consistent. However, the coefficient C is not a pure number. Rather, it has units of (length)$^{1/2}$/time (i.e., (acceleration)$^{1/2}$).

[4]Other methods of evaluating C include the *Kutter equation* (also known as the *G.K. formula*) and the *Bazin formula.* These methods are interesting from a historical viewpoint, but both have been replaced by the Manning equation.

[5]This equation was originally proposed in 1868 by Gaukler and again in 1881 by Hagen, both working independently. For some reason, the Frenchman Flamant attributed the equation to an Irishman, R. Manning. In Europe and many other places, the Manning equation may be known as the *Strickler equation.*

From App. 19.A, the roughness coefficient for finished concrete is 0.012. The Manning coefficient is determined by Eq. 19.11(b).

$$\begin{aligned} C &= \left(\frac{1.49}{n}\right) R^{\frac{1}{6}} \\ &= \left(\frac{1.49}{0.012}\right) (2.22 \text{ ft})^{\frac{1}{6}} \\ &= 141.8 \end{aligned}$$

The discharge is

$$\begin{aligned} Q &= vA = C\sqrt{RS}A \\ &= \left(141.8 \frac{\sqrt{\text{ft}}}{\text{sec}}\right) \left(\sqrt{(2.22 \text{ ft})(0.002)}\right) (8 \text{ ft})(5 \text{ ft}) \\ &= 377.9 \text{ ft}^3/\text{sec} \end{aligned}$$

7. VARIATIONS IN THE MANNING CONSTANT

The Manning coefficient, n, actually varies with depth. For most calculations, however, n is assumed to be constant. The accuracy of other parameters used in open-flow calculations often does not warrant considering the variation of n with depth, and the choice to use a constant or varying n value is left to the individual designer.

If it is desired to acknowledge variations in n with respect to depth, it is expedient to use tables or graphs of hydraulic elements prepared for that purpose. Table 19.3 lists such hydraulic elements under the assumption that n varies. (Appendix 19.C can be used for both varying and constant n.)

Table 19.3 *Circular Channel Ratios (varying n)*

$\frac{d}{D}$	$\frac{Q}{Q_{\text{full}}}$	$\frac{v}{v_{\text{full}}}$
0.1	0.02	0.31
0.2	0.07	0.48
0.3	0.14	0.61
0.4	0.26	0.71
0.5	0.41	0.80
0.6	0.56	0.88
0.7	0.72	0.95
0.8	0.87	1.01
0.9	0.99	1.04
0.95	1.02	1.03
1.00	1.00	1.00

Example 19.2

2.5 ft^3/sec (0.07 m^3/s) of water flow in a 20 in (0.5 m) sewer line ($n = 0.015$, $S = 0.001$). The Manning coefficient, n, varies with depth. Flow is uniform and steady. What are the velocity and depth?

SI Solution

The hydraulic radius is

$$R = \frac{D}{4} = \frac{0.5 \text{ m}}{4} = 0.125 \text{ m}$$

From Eq. 19.12(a),

$$\begin{aligned} v_{\text{full}} &= \left(\frac{1.00}{n}\right) R^{\frac{2}{3}} \sqrt{S} \\ &= \left(\frac{1.00}{0.015}\right) (0.125 \text{ m})^{\frac{2}{3}} \sqrt{0.001} \\ &= 0.53 \text{ m/s} \end{aligned}$$

If the pipe were flowing full, it would carry Q_{full}.

$$\begin{aligned} Q_{\text{full}} &= v_{\text{full}} A \\ &= \left(0.53 \frac{\text{m}}{\text{s}}\right) \left(\frac{\pi}{4}\right) (0.5 \text{ m})^2 \\ &= 0.10 \text{ m}^3/\text{s} \end{aligned}$$

$$\frac{Q}{Q_{\text{full}}} = \frac{0.07 \frac{\text{m}^3}{\text{s}}}{0.10 \frac{\text{m}^3}{\text{s}}} = 0.7$$

From App. 19.C, $d/D = 0.68$ and $v/v_{\text{full}} = 0.94$.

$$\begin{aligned} v &= (0.94)\left(0.53 \frac{\text{m}}{\text{s}}\right) = 0.50 \text{ m/s} \\ d &= (0.68)(0.5 \text{ m}) = 0.34 \text{ m} \end{aligned}$$

Customary U.S. Solution

The hydraulic radius is

$$R = \frac{D}{4} = \frac{\frac{20 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}}{4} = 0.417 \text{ ft}$$

From Eq. 19.12(b),

$$\begin{aligned} v_{\text{full}} &= \left(\frac{1.49}{n}\right) R^{\frac{2}{3}} \sqrt{S} \\ &= \left(\frac{1.49}{0.015}\right) (0.417 \text{ ft})^{\frac{2}{3}} \sqrt{0.001} \\ &= 1.75 \text{ ft/sec} \end{aligned}$$

If the pipe were flowing full, it would carry Q_{full}.

$$\begin{aligned} Q_{\text{full}} &= v_{\text{full}} A \\ &= \left(1.75 \frac{\text{ft}}{\text{sec}}\right) \left(\frac{\pi}{4}\right) \left(\frac{20 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}\right)^2 \\ &= 3.83 \text{ ft}^3/\text{sec} \end{aligned}$$

$$\frac{Q}{Q_{\text{full}}} = \frac{2.5 \frac{\text{ft}^3}{\text{sec}}}{3.83 \frac{\text{ft}^3}{\text{sec}}} = 0.65$$

From App. 19.C, $d/D = 0.66$ and $v/v_{full} = 0.92$.

$$v = (0.92)\left(1.75 \frac{ft}{sec}\right) = 1.61 \text{ ft/sec}$$

$$d = (0.66)(20 \text{ in}) = 13.2 \text{ in}$$

8. HAZEN-WILLIAMS VELOCITY

The empirical Hazen-Williams open channel velocity equation was developed in the early 1920s. It is still occasionally used in the United States for sizing gravity sewers. It is applicable to water flows at reasonably high Reynolds numbers and is based on sound dimensional analysis. However, the constants and exponents were developed experimentally.

The equation uses the Hazen-Williams constant, C, to characterize the roughness of the channel. Since the equation is used only for water within "normal" ambient conditions, the effects of temperature, pressure, and viscosity are disregarded. The primary advantage of this approach is that the constant, C, depends only on the roughness, not on the fluid characteristics. This is also the method's main disadvantage, since professional judgment is required in choosing the value of C.

$$v = 0.85CR^{0.63}S_0^{0.54} \quad [SI] \quad 19.14(a)$$

$$v = 1.318CR^{0.63}S_0^{0.54} \quad [U.S.] \quad 19.14(b)$$

9. NORMAL DEPTH

When the depth of flow is constant along the length of the channel (i.e., the depth is neither increasing nor decreasing), the flow is said to be *uniform*. The depth of flow in that case is known as the *normal depth*, d_n. If the normal depth is known, it can be compared with the actual depth of flow to determine if the flow is uniform.[6]

The difficulty with which the normal depth is calculated depends on the cross section of the channel. If the width is very large compared to the depth, the flow cross section will essentially be rectangular and the Manning equation can be used. (Equation 19.15 assumes that the hydraulic radius equals the normal depth.)

$$d_n = \left(\frac{nQ}{w\sqrt{S}}\right)^{\frac{3}{5}} \quad [w \gg d_n] \quad [SI] \quad 19.15(a)$$

$$d_n = 0.788\left(\frac{nQ}{w\sqrt{S}}\right)^{\frac{3}{5}} \quad [w \gg d_n] \quad [U.S.] \quad 19.15(b)$$

Normal depth in circular channels can be calculated directly only under limited conditions. If the circular channel is flowing full, the normal depth is the inside pipe diameter.

[6]Normal depth is a term that applies only to uniform flow. The two alternate depths that can occur in nonuniform flow are not normal depths.

$$D = d_n = 1.548\left(\frac{nQ}{\sqrt{S}}\right)^{\frac{3}{8}} \quad [full] \quad [SI] \quad 19.16(a)$$

$$D = d_n = 1.335\left(\frac{nQ}{\sqrt{S}}\right)^{\frac{3}{8}} \quad [full] \quad [U.S.] \quad 19.16(b)$$

If a circular channel is flowing half full, the normal depth is half of the inside pipe diameter.

$$D = 2d_n = 2.008\left(\frac{nQ}{\sqrt{S}}\right)^{\frac{3}{8}} \quad [half full] \quad [SI] \quad 19.17(a)$$

$$D = 2d_n = 1.731\left(\frac{nQ}{\sqrt{S}}\right)^{\frac{3}{8}} \quad [half full] \quad [U.S.] \quad 19.17(b)$$

For other cases of uniform flow (trapezoidal, triangular, etc.), it is more difficult to determine normal depth. Various researchers have prepared tables and figures to assist in the calculations. For example, Table 19.3 is derived from App. 19.C and can be used for circular channels flowing other than full or half full.

In the absence of tables or figures, trial-and-error solutions are required. The appropriate expressions for the flow area and hydraulic radius are used in the Manning equation. Trial values are used in conjunction with graphical techniques, linear interpolation, or extrapolation to determine the normal depth. The Manning equation is solved for flow rate with various assumed values of d_n. The calculated value is compared to the actual known flow quantity, and the normal depth is approached iteratively.

For a rectangular channel whose width is small compared to the depth, the hydraulic radius and area in flow are

$$R = \frac{wd_n}{w + 2d_n} \quad 19.18$$

$$A = wd_n \quad 19.19$$

$$Q = \left(\frac{1.00}{n}\right)(wd_n)\left(\frac{wd_n}{w + 2d_n}\right)^{\frac{2}{3}}\sqrt{S} \quad [rectangular] \quad [SI] \quad 19.20(a)$$

$$Q = \left(\frac{1.49}{n}\right)(wd_n)\left(\frac{wd_n}{w + 2d_n}\right)^{\frac{2}{3}}\sqrt{S} \quad [rectangular] \quad [U.S.] \quad 19.20(b)$$

For a trapezoidal channel with exposed surface width w, base width b, side length s, and normal depth of flow d_n, the hydraulic radius and area in flow are

$$R = \frac{d_n(b + w)}{2(b + 2s)} \quad [trapezoidal] \quad 19.21$$

$$A = \frac{h(w + b)}{2} \quad [trapezoidal] \quad 19.22$$

For a symmetrical triangular channel with exposed surface width w, side slope 1:z (vertical:horizontal), and normal depth of flow d_n, the hydraulic radius and area in flow are

$$R = \frac{zd_n}{2\sqrt{1+z^2}} \qquad 19.23$$

$$A = zd_n^2 \qquad 19.24$$

10. ENERGY AND FRICTION RELATIONSHIPS

Bernoulli's equation is an expression for the conservation of energy along a fluid streamline. The Bernoulli equation can also be written for two points along the bottom of an open channel.

$$\frac{p_1}{\rho g} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\rho g} + \frac{v_2^2}{2g} + z_2 + h_f \quad \text{[SI]} \qquad 19.25(a)$$

$$\frac{p_1}{\gamma} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\gamma} + \frac{v_2^2}{2g} + z_2 + h_f \quad \text{[U.S.]} \qquad 19.25(b)$$

However, $p/\rho g = d$.

$$d_1 + \frac{v_1^2}{2g} + z_1 = d_2 + \frac{v_2^2}{2g} + z_2 + h_f \qquad 19.26$$

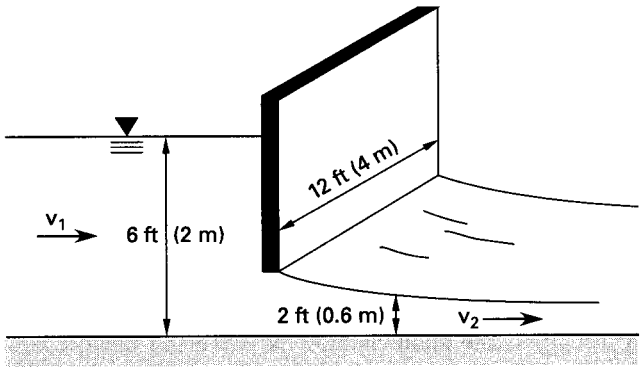
And since $d_1 = d_2$ and $v_1 = v_2$ for uniform flow at the bottom of a channel,

$$h_f = z_1 - z_2 \qquad 19.27$$

$$S_0 = \frac{z_1 - z_2}{L} \qquad 19.28$$

The channel slope, S_0, and the hydraulic energy gradient, S, are numerically the same for uniform flow. Therefore, the total friction loss along a channel is

$$h_f = LS \qquad 19.29$$



Combining Eq. 19.29 with the Manning equation results in a method for calculating friction loss.

$$h_f = \frac{Ln^2v^2}{R^{\frac{4}{3}}} \quad \text{[SI]} \qquad 19.30(a)$$

$$h_f = \frac{Ln^2v^2}{2.208R^{\frac{4}{3}}} \quad \text{[U.S.]} \qquad 19.30(b)$$

Example 19.3

The velocities upstream and downstream, v_1 and v_2, of a 12 ft (4.0 m) wide sluice gate are both unknown. The upstream and downstream depths are 6 ft (2.0 m) and 2 ft (0.6 m), respectively. Flow is uniform and steady. What is the downstream velocity, v_2?

SI Solution

Since the channel bottom is essentially level on either side of the gate, $z_1 = z_2$. Bernoulli's equation reduces to

$$d_1 + \frac{v_1^2}{2g} = d_2 + \frac{v_2^2}{2g}$$

$$2\text{ m} + \frac{v_1^2}{2g} = 0.6\text{ m} + \frac{v_2^2}{2g}$$

v_1 and v_2 are related by continuity.

$$Q_1 = Q_2$$
$$A_1v_1 = A_2v_2$$
$$(2\text{ m})(4\text{ m})v_1 = (0.6\text{ m})(4\text{ m})v_2$$
$$v_1 = 0.3v_2$$

Substituting the expression for v_1 into the Bernoulli equation gives

$$2\text{ m} + \frac{(0.3)^2v_2^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)} = 0.6\text{ m} + \frac{v_2^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}$$
$$2\text{ m} + 0.004587v_2^2 = 0.6\text{ m} + 0.050968v_2^2$$
$$v_2 = 5.5\text{ m/s}$$

Customary U.S. Solution

Since the channel bottom is essentially level on either side of the gate, $z_1 = z_2$. Bernoulli's equation reduces to

$$d_1 + \frac{v_1^2}{2g} = d_2 + \frac{v_2^2}{2g}$$

$$6\text{ ft} + \frac{v_1^2}{2g} = 2\text{ ft} + \frac{v_2^2}{2g}$$

v_1 and v_2 are related by continuity.

$$Q_1 = Q_2$$
$$A_1v_1 = A_2v_2$$
$$(6\text{ ft})(12\text{ ft})v_1 = (2\text{ ft})(12\text{ ft})v_2$$
$$v_1 = \frac{v_2}{3}$$

Substituting the expression for v_1 into the Bernoulli equation gives

$$6\text{ ft} + \frac{v_2^2}{(3)^2(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)} = 2\text{ ft} + \frac{v_2^2}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}$$

$$6\text{ ft} + 0.00173v_2^2 = 2\text{ ft} + 0.0155v_2^2$$

$$v_2 = 17.0\text{ ft/sec}$$

Example 19.4

In Ex. 19.1, the open channel experiencing normal flow had the following characteristics: $S = 0.002$, $n = 0.012$, $v = 9.447$ ft/sec (2.9 m/s), and $R = 2.22$ ft (0.68 m). What is the energy loss per 1000 ft (100 m)?

SI Solution

There are two methods for finding the energy loss. From Eq. 19.29,

$$h_f = LS = (100\text{ m})(0.002)$$
$$= 0.2\text{ m}$$

From Eq. 19.30(a),

$$h_f = \frac{Ln^2v^2}{R^{\frac{4}{3}}}$$
$$= \frac{(100\text{ m})(0.012)^2\left(2.9\ \frac{\text{m}}{\text{s}}\right)^2}{(0.68\text{ m})^{\frac{4}{3}}}$$
$$= 0.2\text{ m}$$

Customary U.S. Solution

There are two methods for finding the energy loss. From Eq. 19.29,

$$h_f = LS = (1000\text{ ft})(0.002)$$
$$= 2\text{ ft}$$

From Eq. 19.30(b),

$$h_f = \frac{Ln^2v^2}{2.208R^{\frac{4}{3}}}$$
$$= \frac{(1000\text{ ft})(0.012)^2\left(9.447\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2.208)(2.22\text{ ft})^{\frac{4}{3}}}$$
$$= 2\text{ ft}$$

11. SIZING TRAPEZOIDAL AND RECTANGULAR CHANNELS

Trapezoidal and rectangular cross sections are commonly used for artificial surface channels. The flow through a trapezoidal channel is easily determined from the Manning equation when the cross section is known. However, when the cross section or uniform depth is unknown, a trial-and-error solution is required.

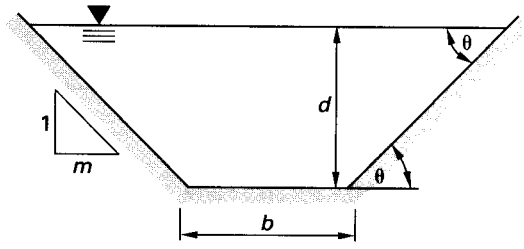


Figure 19.2 *Trapezoidal Cross Section*

For such problems involving rectangular and trapezoidal channels, it is common to calculate and plot the *conveyance*, K (or alternatively, the product Kn), against depth. For trapezoidal sections, it is particularly convenient to write the uniform flow, Q, in terms of a modified conveyance, K'. b is the base width of the channel, d is the depth of flow, and m is the cotangent of the side slope angle. m and the ratio d/b are treated as independent variables.

$$Q = \frac{K'b^{\frac{8}{3}}\sqrt{S_0}}{n} \qquad 19.31$$

$$K' = \left(\frac{1 + m\left(\frac{d}{b}\right)^{\frac{5}{3}}}{\left(1 + 2\left(\frac{d}{b}\right)\sqrt{1+m^2}\right)^{\frac{2}{3}}}\right)\left(\frac{d}{b}\right)^{\frac{5}{3}}$$

[SI] 19.32(a)

$$K' = \left(\frac{1.49\left(1 + m\left(\frac{d}{b}\right)^{\frac{5}{3}}\right)}{\left(1 + 2\left(\frac{d}{b}\right)\sqrt{1+m^2}\right)^{\frac{2}{3}}}\right)\left(\frac{d}{b}\right)^{\frac{5}{3}}$$

[U.S.] 19.32(b)

$$m = \cot\theta \qquad 19.33$$

For any fixed value of m, enough values of K' are calculated over a reasonable range of the d/b ratio ($0.05 < d/b < 0.5$) to define a curve. Then, given specific values of Q, n, S_0, and b, the value of K' can be calculated from the expression for Q. The graph is used to determine the ratio d/b, giving the depth of uniform flow, d, since b is known.

When the ratio of d/b is very small (less than 0.02), it is satisfactory to consider the trapezoidal channel as a wide rectangular channel with area $A = bd$.

12. MOST EFFICIENT CROSS SECTION

The most efficient open channel cross section will maximize the flow for a given Manning coefficient, slope, and flow area. Accordingly, the Manning equation requires that the hydraulic radius be maximum. For a given flow area, the wetted perimeter will be minimum.

Semicircular cross sections have the smallest wetted perimeter; therefore, the cross section with the highest efficiency is the semicircle. Although such a shape can be constructed with concrete, it cannot be used with earth channels.

The most efficient cross section is also generally assumed to minimize construction cost. This is true only in the most simplified cases, however, since the labor and material costs of excavation and formwork must be considered. Rectangular and trapezoidal channels are much easier to form than semicircular channels. So in this sense the "least efficient" (i.e, most expensive) cross section (i.e., semicircular) is also the "most efficient."

The most efficient rectangle is one having depth equal to one-half of the width (i.e., is one-half of a square).

$$d = \frac{w}{2} \quad \text{[most efficient rectangle]} \qquad 19.34$$

$$A = dw = \frac{w^2}{2} = 2d^2 \qquad 19.35$$

$$P = d + w + d = 2w = 4d \qquad 19.36$$

$$R = \frac{w}{4} = \frac{d}{2} \qquad 19.37$$

The most efficient trapezoidal channel is always one in which the flow depth is twice the hydraulic radius. If the side slope is adjustable, the sides of the most efficient trapezoid should be inclined at 60° from the horizontal. Since the surface width will be equal to twice the sloping side length, the most efficient trapezoidal channel will be half of a regular hexagon (i.e., three adjacent equilateral triangles of side length $2d/\sqrt{3}$). If the side slope is any other angle, only the $d = 2R$ criterion is applicable.

$$d = 2R \quad \text{[most efficient trapezoid]} \qquad 19.38$$

$$b = \frac{2d}{\sqrt{3}} \qquad 19.39$$

$$A = \sqrt{3}d^2 \qquad 19.40$$

$$P = 2\sqrt{3}d \qquad 19.41$$

$$R = \frac{d}{2} \qquad 19.42$$

A semicircle with its center at the middle of the water surface can always be inscribed in a cross section with maximum efficiency.

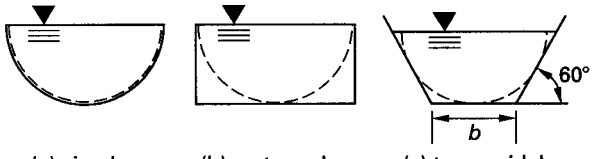

Figure 19.3 *Circles Inscribed in Efficient Channels*

Example 19.5

A rubble masonry open channel is being designed to carry 500 ft^3/sec (14 m^3/s) of water on a 0.0001 slope. Using $n = 0.017$, find the most efficient dimensions for a rectangular channel.

SI Solution

Let the depth and width be d and w, respectively. For an efficient rectangle, $d = w/2$.

$$A = dw = \left(\frac{w}{2}\right) w = \frac{w^2}{2}$$

$$P = d + w + d = \frac{w}{2} + w + \frac{w}{2} = 2w$$

$$R = \frac{A}{P} = \frac{\frac{w^2}{2}}{2w} = \frac{w}{4}$$

Using Eq. 19.13(a),

$$Q = \left(\frac{1.00}{n}\right) AR^{\frac{2}{3}}\sqrt{S}$$

$$14\ \text{m}^3/\text{s} = \left(\frac{1.00}{0.017}\right)\left(\frac{w^2}{2}\right)\left(\frac{w}{4}\right)^{\frac{2}{3}}\sqrt{0.0001}$$

$$14\ \text{m}^3/\text{s} = 0.1167w^{\frac{8}{3}}$$

$$w = 6.02\ \text{m}$$

$$d = \frac{w}{2} = \frac{6.02\ \text{m}}{2} = 3.01\ \text{m}$$

Customary U.S. Solution

Let the depth and width be d and w, respectively. For an efficient rectangle, $d = w/2$.

$$A = dw = \left(\frac{w}{2}\right) w = \frac{w^2}{2}$$

$$P = d + w + d = \frac{w}{2} + w + \frac{w}{2} = 2w$$

$$R = \frac{A}{P} = \frac{\frac{w^2}{2}}{2w} = \frac{w}{4}$$

Using Eq. 19.13(b),

$$Q = \left(\frac{1.49}{n}\right) AR^{\frac{2}{3}}\sqrt{S}$$

$$500\ \text{ft}^3/\text{sec} = \left(\frac{1.49}{0.017}\right)\left(\frac{w^2}{2}\right)\left(\frac{w}{4}\right)^{\frac{2}{3}}\sqrt{0.0001}$$

$$500\ \text{ft}^3/\text{sec} = 0.1739w^{\frac{8}{3}}$$

$$w = 19.82\ \text{ft}$$

$$d = \frac{w}{2} = \frac{19.82\ \text{ft}}{2} = 9.91\ \text{ft}$$

13. ANALYSIS OF NATURAL WATERCOURSES

Natural watercourses do not have uniform paths or cross sections. This complicates their analysis considerably. Frequently, analyzing the flow from a river is a matter of making the most logical assumptions. Many evaluations can be solved with a reasonable amount of error.

As was seen in Eq. 19.30, the friction loss (and hence the hydraulic gradient) depends on the square of the roughness coefficient. Therefore, an attempt must be made to evaluate the roughness constant as accurately as possible. If the channel consists of a river with flood plains, it should be treated as parallel channels. The flow from each subdivision can be calculated independently and the separate values added to obtain the total flow. Alternatively, a composite value of the roughness coefficient, n_c, can be approximated from the individual values of n and the corresponding wetted perimeters.

$$n_c = \left(\frac{\sum P_i (n_i)^{\frac{3}{2}}}{\sum P_i} \right)^{\frac{2}{3}} \qquad 19.43$$

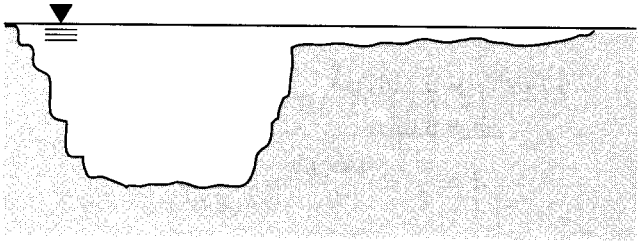

Figure 19.4 *River with Flood Plain*

If the channel is divided by an island into two channels, some combination of flows will usually be known. For example, if the total flow, Q, is known, Q_1 and Q_2 may be unknown. If the slope is known, Q_1 and Q_2 may be known. Iterative trial-and-error solutions are often required.

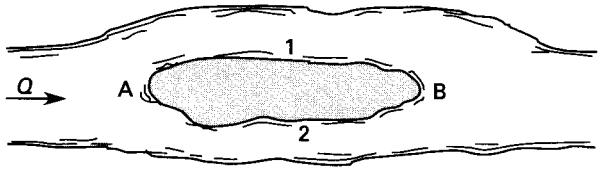

Figure 19.5 *Divided Channel*

Since the elevation drop ($z_A - z_B$) between points A and B is the same regardless of flow path,

$$S_1 = \frac{z_A - z_B}{L_1} \qquad 19.44$$

$$S_2 = \frac{z_A - z_B}{L_2} \qquad 19.45$$

Once the slopes are known, initial estimates Q_1 and Q_2 can be calculated from Eq. 19.13. The sum of Q_1 and Q_2 will probably not be the same as the given flow quantity, Q. In that case, Q should be prorated according to the ratios of Q_1 and Q_2 to $Q_1 + Q_2$.

If the lengths L_1 and L_2 are the same or almost so, the Manning equation may be solved for the slope by writing Eq. 19.46.

$$Q = Q_1 + Q_2 = \left(\left(\frac{A_1}{n_1} \right) (R_1)^{\frac{2}{3}} + \left(\frac{A_2}{n_2} \right) (R_2)^{\frac{2}{3}} \right) \sqrt{S} \qquad \text{[SI]} \quad 19.46(a)$$

$$Q = Q_1 + Q_2 = 1.49 \left(\left(\frac{A_1}{n_1} \right) (R_1)^{\frac{2}{3}} + \left(\frac{A_2}{n_2} \right) (R_2)^{\frac{2}{3}} \right) \sqrt{S} \qquad \text{[U.S.]} \quad 19.46(b)$$

Equation 19.46 yields only a rough estimate of the flow quantity, as the geometry and roughness of a natural channel changes considerably along its course.

14. FLOW MEASUREMENT WITH WEIRS

A *weir* is an obstruction in an open channel over which flow occurs. Although a dam spillway is a specific type of weir, most weirs are intended specifically for flow measurement.

Measurement weirs consist of a vertical flat plate with sharp edges. Because of their construction, they are called *sharp-crested weirs*. Sharp-crested weirs are most frequently rectangular, consisting of a straight, horizontal crest. However, weirs may also have trapezoidal and triangular openings.

For any given width of weir opening (referred to as the *weir length*), the discharge will be a function of the head over the weir. The head (or sometimes surface elevation) can be determined by a standard *staff gauge* mounted adjacent to the weir.

The full channel flow usually goes over the weir. However, it is also possible to divert a small portion of the total flow through a measurement channel. The full channel flow rate can be extrapolated from a knowledge of the split fractions.

If a rectangular weir is constructed with an opening width less than the channel width, the falling liquid sheet (called the *nappe*) decreases in width as it falls. Because of this *contraction* of the nappe, these weirs are known as *contracted weirs*, although it is the nappe that is actually contracted, not the weir. If the opening of the weir extends the full channel width, the weir is known as a *suppressed weir*, since the contractions are suppressed.

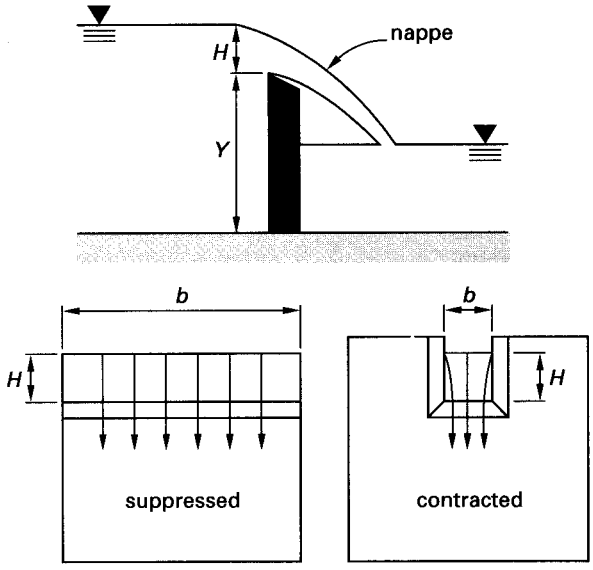

Figure 19.6 *Contracted and Suppressed Weirs*

The derivation of an expression for the quantity flowing over a weir is dependent on many simplifying assumptions. The basic weir equation (Eq. 19.47 or 19.48) is, therefore, an approximate result requiring correction by experimental coefficients.

If it is assumed that the contractions are suppressed, upstream velocity is uniform, flow is laminar over the crest, nappe pressure is zero, the nappe is fully ventilated, and viscosity, turbulence, and surface tension effects are negligible, then the following equation may be derived from the Bernoulli equation.

$$Q = \tfrac{2}{3} b\sqrt{2g}\left(\left(H + \frac{v_1^2}{2g}\right)^{\frac{3}{2}} - \left(\frac{v_1^2}{2g}\right)^{\frac{3}{2}}\right) \qquad 19.47$$

If the velocity of approach, v_1, is negligible, then

$$Q = \tfrac{2}{3} b\sqrt{2g} H^{\frac{3}{2}} \qquad 19.48$$

Equation 19.48 must be corrected for all of the assumptions made, primarily for a nonuniform velocity distribution. This is done by introducing an empirical discharge coefficient, C_1. Equation 19.49 is known as the *Francis weir equation.*

$$Q = \tfrac{2}{3} C_1 b\sqrt{2g} H^{\frac{3}{2}} \qquad 19.49$$

Many investigations have been done to evaluate C_1 analytically. Perhaps the most widely known is the coefficient formula developed by *Rehbock.*[7]

[7]There is much variation in how different investigators calculate the discharge coefficient, C_1. For ratios of H/b less than 5, $C_1 = 0.622$ gives a reasonable value. With the questionable accuracy of some of the other variables used in open channel flow problems, the pursuit of greater accuracy is of dubious value.

$$C_1 = \left(0.6035 + 0.0813\left(\frac{H}{Y}\right) + \frac{0.000295}{Y}\right) \times \left(1 + \frac{0.00361}{H}\right)^{\frac{3}{2}} \quad \text{[U.S. only]}$$

$$\approx 0.602 + 0.083(H/Y) \quad \text{[U.S. and SI]} \qquad 19.50$$

When $H/Y < 5$, C_1 approaches 0.61 to 0.62. In most cases, a value in this range is adequate. Other constants (i.e., $^2/_3$ and $\sqrt{2g}$, can be taken out of Eq. 19.49. In that case,

$$Q \approx 1.84 b h^{\frac{3}{2}} \quad \text{[SI]} \qquad 19.51(a)$$

$$Q \approx 3.33 b h^{\frac{3}{2}} \quad \text{[U.S.]} \qquad 19.51(b)$$

If the contractions are not suppressed (i.e., one or both sides do not extend to the channel sides) then the actual width, b, should be replaced with the *effective width.* In Eq. 19.52, N is 1 if one side is contracted and N is 2 if there are two end contractions.

$$b_{\text{effective}} = b_{\text{actual}} - 0.1NH \qquad 19.52$$

A *submerged rectangular weir* requires a more complex analysis because of the difficulty in measuring H and because the discharge depends on both the upstream and downstream depths. The following equation, however, may be used with little difficulty.

$$Q_{\text{submerged}} = Q_{\text{free flow}}\left(1 - \left(\frac{H_{\text{downstream}}}{H_{\text{upstream}}}\right)^{\frac{3}{2}}\right)^{0.385} \qquad 19.53$$

Equation 19.53 is used by first finding the flow rate, Q, from Eq. 19.49 and then correcting it with the bracketed quantity.

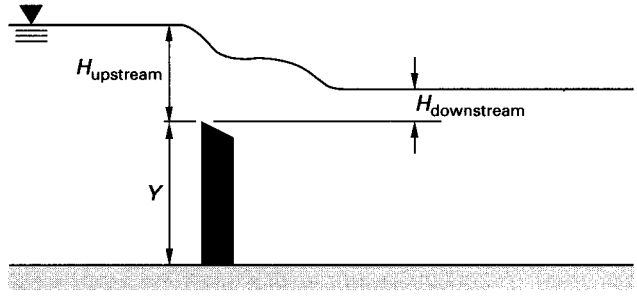

Figure 19.7 *Submerged Weir*

Example 19.6

The crest of a sharp-crested, rectangular weir with two contractions is 2.5 ft (1.0 m) high above the channel bottom. The crest is 4 ft (1.6 m) long. A 4 in (100 mm) head exists over the weir. What is the velocity of approach?

SI Solution

The number of contractions, N, is 2. From Eq. 19.52, the effective width is

$$H = \frac{100 \text{ mm}}{1000 \frac{\text{mm}}{\text{m}}} = 0.1 \text{ m}$$

$$b_{\text{effective}} = b_{\text{actual}} - 0.1NH = 1.6 \text{ m} - (0.1)(2)(0.1 \text{ m})$$
$$= 1.58 \text{ m}$$

$$C_1 \approx 0.602 + 0.083\left(\frac{H}{Y}\right)$$
$$= 0.602 + (0.083)\left(\frac{0.1}{1}\right) = 0.61$$

From Eq. 19.49, the flow is

$$Q = \tfrac{2}{3}C_1 b\sqrt{2g}H^{\frac{3}{2}}$$
$$= \left(\tfrac{2}{3}\right)(0.61)(1.58 \text{ m})\sqrt{(2)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)}(0.10 \text{ m})^{\frac{3}{2}}$$
$$= 0.090 \text{ m}^3/\text{s}$$

$$\text{v} = \frac{Q}{A}$$
$$= \frac{0.090 \frac{\text{m}^3}{\text{s}}}{(1.6 \text{ m})(1.0 \text{ m} + 0.1 \text{ m})}$$
$$= 0.05 \text{ m/s}$$

Customary U.S. Solution

The number of contractions, N, is 2. From Eq. 19.52, the effective width is

$$H = \frac{4 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} = 0.333 \text{ ft}$$

$$b_{\text{effective}} = b_{\text{actual}} - 0.1NH = 4 \text{ ft} - (0.1)(2)(0.333 \text{ ft})$$
$$= 3.93 \text{ ft}$$

The Rehbock coefficient (Eq. 19.50) is

$$C_1 = \left[0.6035 + 0.0813\left(\frac{H}{Y}\right) + \left(\frac{0.000295}{Y}\right)\right]\left(1 + \frac{0.00361}{H}\right)^{\frac{3}{2}}$$
$$= \left(0.6035 + (0.0813)\left(\frac{0.333 \text{ ft}}{2.5 \text{ ft}}\right) + \frac{0.000295}{2.5 \text{ ft}}\right) \times \left(1 + \frac{0.00361^{\frac{3}{2}}}{0.333 \text{ ft}}\right)$$
$$= 0.624$$

From Eq. 19.49, the flow is

$$Q = \tfrac{2}{3}C_1 b\sqrt{2g}H^{\frac{3}{2}}$$
$$= \left(\tfrac{2}{3}\right)(0.624)(3.93 \text{ ft})\sqrt{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)}(0.333 \text{ ft})^{\frac{3}{2}}$$
$$= 2.52 \frac{\text{ft}^3}{\text{sec}}$$

$$\text{v} = \frac{Q}{A}$$
$$= \frac{2.52 \frac{\text{ft}^3}{\text{sec}}}{(4 \text{ ft})(2.5 \text{ ft} + 0.333 \text{ ft})}$$
$$= 0.222 \text{ ft/sec}$$

15. TRIANGULAR WEIRS

Triangular weirs (*V-notch weirs*) should be used when small flow rates are to be measured. The flow coefficient over a triangular weir depends on the notch angle, θ, but generally varies from 0.58 to 0.61. For a 90° weir, $C_2 \approx 0.593$.

$$Q = C_2\left(\frac{8}{15}\right)\tan\left(\frac{\theta}{2}\right)\sqrt{2g}H^{\frac{5}{2}} \qquad 19.54$$

$$Q \approx 1.4H^{2.5} \quad [90° \text{ weir}] \quad [\text{SI}] \qquad 19.55(a)$$

$$Q \approx 2.5H^{2.5} \quad [90° \text{ weir}] \quad [\text{U.S.}] \qquad 19.55(b)$$

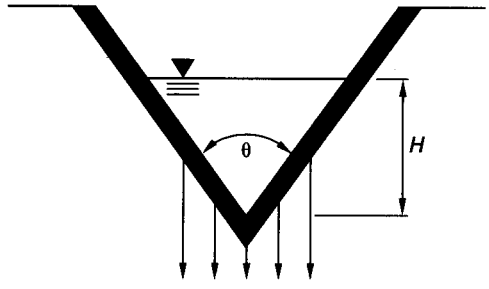

Figure 19.8 *Triangular Weir*

16. TRAPEZOIDAL WEIRS

A *trapezoidal weir* is essentially a rectangular weir with a triangular weir on either side. If the angle of the sides from the vertical is approximately 14° (i.e., 4 vertical and 1 horizontal), the weir is known as a *Cipoletti weir*. The discharge from the triangular ends of a Cipoletti weir approximately make up for the contractions that would reduce the flow over a rectangular weir. Therefore, no correction is theoretically necessary. This is not completely accurate, and for this reason, Cipoletti weirs are not used where great accuracy is required. The discharge is

$$Q = \tfrac{2}{3}C_d b\sqrt{2g}H^{\frac{3}{2}} \qquad 19.56$$

The average value of the discharge coefficient is 0.63. The discharge from a Cipoletti weir is given by Eq. 19.57.

$$Q = 1.86bH^{\frac{3}{2}} \quad \text{[SI]} \qquad 19.57(a)$$

$$Q = 3.367bH^{\frac{3}{2}} \quad \text{[U.S.]} \qquad 19.57(b)$$

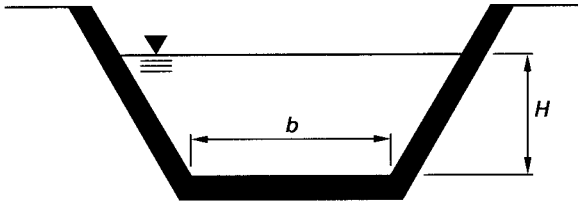

Figure 19.9 *Trapezoidal Weir*

17. BROAD-CRESTED WEIRS AND SPILLWAYS

Most weirs used for flow measurement are sharp-crested. However, the flow over spillways, broad-crested weirs, and similar features can be calculated from Eq. 19.49 even though flow measurement is not the primary function of the feature. (A weir is broad-crested if the weir thickness is greater than half of the head, H.)

A *spillway* (*overflow spillway*) is designed for a capacity based on the dam's inflow hydrograph, turbine capacity, and storage capacity. Spillways frequently have a cross section known as an *ogee*, which closely approximates the underside of a nappe from a sharp-crested weir. This cross section minimizes the cavitation that is likely to occur if the water surface breaks contact with the spillway due to upstream heads that are higher than designed for.[8]

Discharge from an overflow spillway is derived in the same manner as for a weir. Equation 19.58 can be used for broad-crested weirs ($C_1 = 0.5$ to 0.57) and ogee spillways ($C_1 = 0.60$ to 0.75).

$$Q = \tfrac{2}{3}C_1 b\sqrt{2g}H^{\frac{3}{2}} \qquad 19.58$$

The *Horton equation* (Eq. 19.59) for broad-crested weirs combines all of the coefficients into a spillway (weir) coefficient and adds the velocity of approach to the upstream head. The Horton coefficient, C_{Horton}, is specific to the Horton equation.

$$Q = C_{\text{Horton}}b\left(H + \frac{v^2}{2g}\right)^{\frac{3}{2}} \qquad 19.59$$

If the velocity of approach is insignificant, the discharge is

$$Q = C_s bH^{\frac{3}{2}} \qquad 19.60$$

[8]Cavitation and separation will normally not occur as long as the actual head, H, is less than twice the design value. The shape of the ogee spillway will be a function of the design head.

C_s is a *spillway coefficient*, which varies from about 3.3 to 3.98 for ogee spillways. 3.97 is frequently used for first approximations. (Notice that C_s and C_1 differ by a factor of about 5 and cannot easily be mistaken for each other.) For broad-crested weirs, C_s varies between 2.63 and 3.33. (Use 3.33 for initial estimates.) C_s increases as the upstream design head above the spillway top, H, increases, and the larger values apply to the higher heads.

Broad-crested weirs and spillways should be calibrated to obtain greater accuracy in predicting flow rates.

Scour protection is usually needed at the toe of a spillway to protect the area exposed to a hydraulic jump. This protection usually takes the form of an extended horizontal or sloping apron. Other measures, however, are needed if the tailwater exhibits large variations in depth.

18. PROPORTIONAL WEIRS

The *proportional weir* (*Suttro weir*) is used in water level control because it demonstrates a linear relationship between Q and H. Figure 19.10 illustrates a proportional weir whose sides are hyperbolic in shape.

$$Q = C_d K\left(\frac{\pi}{2}\right)\sqrt{2g}H \qquad 19.61$$

$$K = 2x\sqrt{y} \qquad 19.62$$

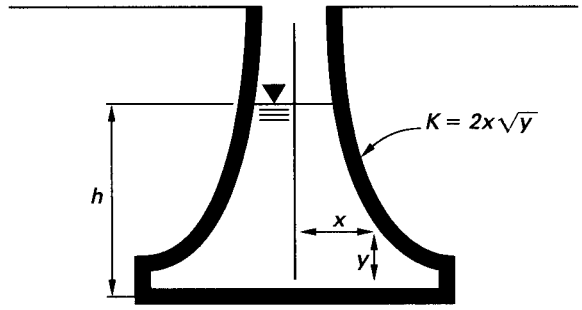

Figure 19.10 *Proportional Weir*

19. FLOW MEASUREMENT WITH PARSHALL FLUMES

The Parshall flume is widely used for measuring open channel wastewater flows. It performs well when head losses must be kept to a minimum and when there are high amounts of suspended solids.

The Parshall flume is constructed with a converging upstream section, a throat, and a diverging downstream section. The walls of the flume are vertical, but the floor of the throat section drops. The length, width, and height of the flume are essentially predefined by the anticipated flow rate.[9]

[9]This chapter does not attempt to design the Parshall flume, only to predict flow rates through its use.

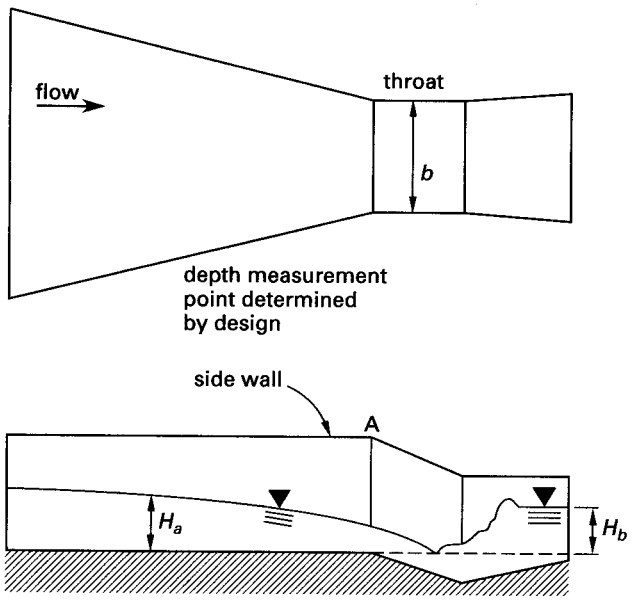

Figure 19.11 *Parshall Flume*

The throat geometry in a Parshall flume has been designed to force the occurrence of critical flow (Sec. 25) at that point. Following the critical section is a short length of supercritical flow followed by a hydraulic jump (Sec. 33). This design eliminates any dead water region where debris and silt can accumulate (as are common with flat-topped weirs).

The discharge relationship for a Parshall flume is given by Eq. 19.63 for submergence ratios of H_b/H_a up to 0.7. Above 0.7, the true discharge is less than predicted by Eq. 19.63. Values of K are given in Table 19.4, although using a value of 4.0 is accurate for most purposes.

$$Q = KbH_a^n \qquad 19.63$$

$$n = 1.522b^{0.026} \qquad 19.64$$

Above a certain tailwater height, the Parshall flume no longer operates in the *free-flow mode*. Rather, it operates in a *submerged mode*. A very high tailwater reduces the flow rate though the flume. Equation 19.63 predicts the flow rate with reasonable accuracy, however, even for 50 to 80% submergence (calculated as H_b/H_a). For large submergence, the tailwater height must be known and a different analysis method must be used.

Table 19.4 *Parshall Flume K-Values*

b, ft (m)	K
0.25 (0.075)	3.97
0.50 (0.15)	4.12
0.75 (0.225)	4.09
1.0 (0.3)	4.00
1.5 (0.45)	4.00
2.0 (0.6)	4.00
3.0 (0.9)	4.00
4.0 (1.2)	4.00

(Multiply ft by 0.3 to obtain m.)

20. UNIFORM AND NONUNIFORM STEADY FLOW

Steady flow is constant-volume flow. However, the flow may be uniform or nonuniform (varied) in depth. There may be significant variations over long and short distances without any change in the flow rate.

Figure 19.12 illustrates the three definitions of "slope" existing for open channel flow. These three slopes are the slope of the channel bottom, the slope of the water surface, and the slope of the energy gradient line.

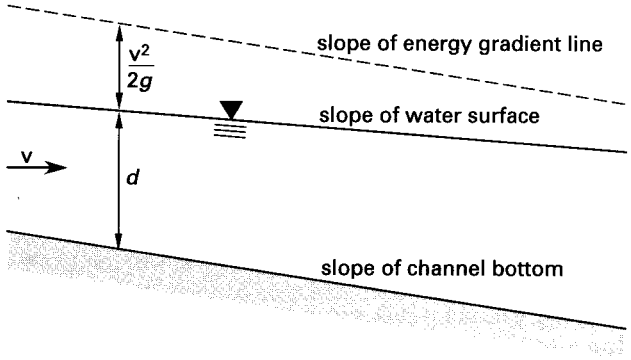

Figure 19.12 *Slopes Used in Open Channel Flow*

Under conditions of uniform flow, all of these three slopes are equal since the flow quantity and flow depth are constant along the length of flow.[10] With nonuniform flow, however, the flow velocity and depth vary along the length of channel and the three slopes are not necessarily equal.

If water is introduced down a path with a steep slope (as after flowing over a spillway), the effect of gravity will cause the velocity to increase. As the velocity increases, the depth decreases in accordance with the continuity of flow equation. The downward velocity is opposed by friction. Because the gravitational force is constant but friction varies with the square of velocity, these two forces eventually become equal. When equal, the velocity stops increasing, the depth stops decreasing, and the flow becomes uniform. Until they become equal, however, the flow is nonuniform (varied).

21. SPECIFIC ENERGY

The total head possessed by a fluid is given by the Bernoulli equation.

$$\frac{p}{\rho g} + \frac{v^2}{2g} + z \qquad \text{[SI]} \qquad 19.65(a)$$

$$\frac{p}{\gamma} + \frac{v^2}{2g} + z \qquad \text{[U.S.]} \qquad 19.65(b)$$

[10] As a simplification, this chapter deals only with channels of constant width. If the width is varied, changes in flow depth may not coincide with changes in flow quantity.

Specific energy, E, is defined as the total head with respect to the channel bottom. In this case, $z = 0$ and $p/\gamma = d$.

$$E = d + \frac{v^2}{2g} \qquad 19.66$$

Equation 19.66 is not meant to imply that the potential energy is an unimportant factor in open channel flow problems. The concept of specific energy is used for convenience only, and it should be clear that the Bernoulli equation is still the valid energy conservation equation.

In uniform flow, total head decreases due to the frictional effects, but specific energy is constant. In nonuniform flow, total head decreases, but specific energy may increase or decrease.

Since $v = Q/A$, Eq. 19.66 can be written as

$$E = d + \frac{Q^2}{2gA^2} \quad \text{[general]} \qquad 19.67$$

For a rectangular channel, the velocity can be written in terms of the width and flow depth.

$$v = \frac{Q}{A} = \frac{Q}{wd} \qquad 19.68$$

The specific energy equation for a rectangular channel is given by Eq. 19.69 and shown in Fig. 19.13.

$$E = d + \frac{Q^2}{2g(wd)^2} \quad \text{[rectangular]} \qquad 19.69$$

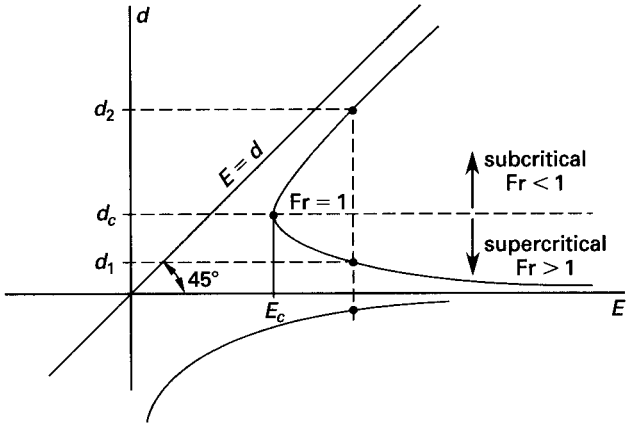

Figure 19.13 *Specific Energy Diagram*

22. SPECIFIC FORCE

The *specific force* of a general channel section is the total force per unit weight acting on the water. Equivalently, specific force is the total force that a submerged object would experience. In Eq. 19.70, $\bar{d}$ is the distance from the free surface to the centroid of the flowing area cross section, A.

$$F\rho g = \frac{Q^2}{gA} + \bar{d}A \quad \text{[SI]} \qquad 19.70(a)$$

$$F\gamma = \frac{Q^2}{gA} + \bar{d}A \quad \text{[U.S.]} \qquad 19.70(b)$$

The first term in Eq. 19.70 represents the momentum flow through the channel per unit time and per unit mass of water. The second term is the pressure force per unit mass of water. Graphs of specific force and specific energy are similar in appearance and predict equivalent results for the critical and alternate depths.

23. CHANNEL TRANSITIONS

Sudden changes in channel width or bottom elevation are known as *channel transitions*. (Contractions in width are not covered in this chapter.) For sudden vertical steps in channel bottom, the Bernoulli equation, written in terms of the specific energy, is used to predict the flow behavior (i.e., the depth).

$$E_1 + z_1 = E_2 + z_2 \qquad 19.71$$

$$E_1 - E_2 = z_2 - z_1 \qquad 19.72$$

The maximum possible change in bottom elevation without affecting the energy equality occurs when the depth of flow over the step is equal to the critical depth (d_2 equals d_c). (See Sec. 25.)

24. ALTERNATE DEPTHS

Since the area depends on the depth, fixing the channel shape and slope and assuming a depth will determine the flow rate, Q, as well as the specific energy. Since Eq. 19.69 is a cubic equation, there are three values of depth of flow, d, that will satisfy it. One of them is negative, as Fig. 19.13 shows. Since depth cannot be negative, that value can be discarded. The two remaining values are known as *alternate depths*.

For a given flow rate, the two alternate depths have the same energy. One represents a high velocity with low depth; the other represents a low velocity with high depth. The former is called *supercritical (rapid) flow*; the latter is called *subcritical (tranquil) flow*.

The Bernoulli equation cannot predict which of the two alternate depths will occur for any given flow quantity. The concept of *accessibility* is required to evaluate the two depths. Specifically, the upper and lower limbs of the energy curve are not accessible from each other unless there is a local restriction in the flow.

Energy curves can be drawn for different flow quantities, as shown in Fig. 19.14 for flow quantities Q_A and Q_B. Suppose that flow is initially at point 1. (Since the flow

is on the upper limb, the flow is initially subcritical.) If there is a step up in the channel bottom, Eq. 19.72 predicts that the specific energy will decrease.

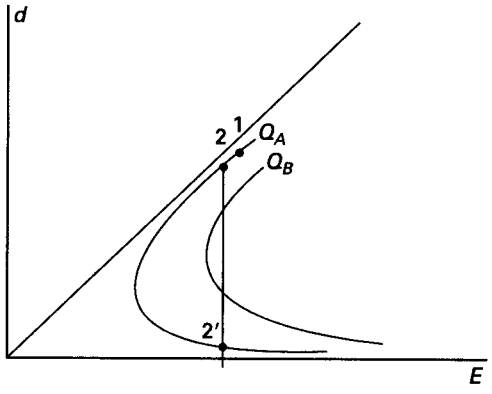

Figure 19.14 *Specific Energy Curve Families*

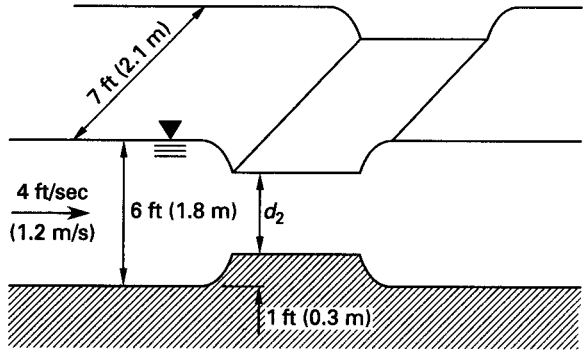
However, the flow cannot arrive at point 2′ without the flow quantity changing (i.e., going through a specific energy curve for a different flow quantity). Therefore, point 2′ is not accessible from point 1 without going through point 2 first.[11]



If the flow is well up on the top limb of the specific energy curve (as it is in Ex. 19.7), the water level will drop only slightly. Since the upper limb is asymptotic to a 45° diagonal line, any change in specific energy will result in almost the same change in depth.[12] Therefore, the surface level will remain almost the same.

$$\Delta d \approx \Delta E \quad \text{[fully subcritical]} \qquad 19.73$$

However, if the initial point on the limb is close to the critical point (i.e., the nose of the curve), then a small change in the specific energy (such as might be caused by a small variation in the channel floor) will cause a large change in depth. That is why severe turbulence commonly occurs near points of critical flow.

Example 19.7

4 ft/sec (1.2 m/s) of water flows in a 7 ft (2.1 m) wide, 6 ft (1.8 m) deep open channel. The flow encounters a 1.0 ft (0.3 m) step in the channel bottom. What is the depth of flow above the step?

SI Solution

The initial specific energy is found from Eq. 19.66.

$$E_1 = d + \frac{v^2}{2g}$$

$$= 1.8 \text{ m} + \frac{\left(1.2 \frac{\text{m}}{\text{s}}\right)^2}{(2)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)} = 1.87 \text{ m}$$

From Eq. 19.72, the specific energy above the step is

$$E_2 = E_1 + z_1 - z_2 = 1.87 \text{ m} + 0 - 0.3 \text{ m}$$
$$= 1.57 \text{ m}$$

The quantity flowing is

$$Q = Av = (2.1 \text{ m})(1.8 \text{ m})\left(1.2 \frac{\text{m}}{\text{s}}\right)$$
$$= 4.54 \text{ m}^3/\text{s}$$

Substituting Q into Eq. 19.69 gives

$$E = d + \frac{Q^2}{2g(wd)^2}$$

$$1.57 \text{ m} = d_2 + \frac{\left(4.54 \frac{\text{m}^3}{\text{s}}\right)^2}{(2)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(2.1 \text{ m})^2(d_2)^2}$$

By trial and error or a calculator's equation solver, the alternate depths are $d_2 = 0.46$ m, 1.46 m.

Since the 0.46 m depth is not accessible from the initial depth of 1.8 m, the depth over the step is 1.5 m. The drop in the water level is

$$1.8 \text{ m} - (1.46 \text{ m} + 0.3 \text{ m}) = 0.04 \text{ m}$$

[11] Actually, specific energy curves are typically plotted for flow per unit width, $q = Q/w$. If that is the case, a jump from one limb to the other could take place if the width were allowed to change as well as depth.

[12] A rise in the channel bottom does not always produce a drop in the water surface. Only if the flow is initially subcritical will the water surface drop upon encountering a step. The water surface will rise if the flow is initially supercritical.

Customary U.S. Solution

The initial specific energy is found from Eq. 19.66.

$$E_1 = d + \frac{v^2}{2g}$$

$$= 6 \text{ ft} + \frac{\left(4 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)} = 6.25 \text{ ft}$$

From Eq. 19.72, the specific energy over the step is

$$E_2 = E_1 + z_1 - z_2 = 6.25 \text{ ft} + 0 - 1 \text{ ft}$$
$$= 5.25 \text{ ft}$$

The quantity flowing is

$$Q = Av = (7 \text{ ft})(6 \text{ ft})\left(4 \frac{\text{ft}}{\text{sec}}\right)$$
$$= 168 \text{ ft}^3/\text{sec}$$

Substituting Q into Eq. 19.69 gives

$$E = d + \frac{Q^2}{2g(wd)^2}$$

$$5.25 \text{ ft} = d_2 + \frac{\left(168 \frac{\text{ft}^3}{\text{sec}}\right)^2}{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(7 \text{ ft})^2 (d_2)^2}$$

By trial and error or a calculator's equation solver, the alternate depths are $d_2 = 1.6$ ft, 4.9 ft.

Since the 1.6 ft depth is not accessible from the initial depth of 6 ft, the depth over the step is 4.9 ft. The drop in the water level is

$$6 \text{ ft} - (4.9 \text{ ft} + 1 \text{ ft}) = 0.1 \text{ ft}$$

25. CRITICAL FLOW AND CRITICAL DEPTH IN RECTANGULAR CHANNELS

There is one depth, known as the *critical depth*, that minimizes the energy of flow. (The depth is not minimized, however.) The critical depth for a given flow depends on the shape of the channel.

For a rectangular channel, if Eq. 19.69 is differentiated with respect to depth in order to minimize the specific energy, Eq. 19.74 results.

$$d_c^3 = \frac{Q^2}{gw^2} \quad \text{[rectangular]} \qquad 19.74$$

Geometrical and analytical methods can be used to correlate the critical depth and the minimum specific energy.

$$d_c = \tfrac{2}{3} E_c \qquad 19.75$$

For a rectangular channel, $Q = d_c w v_c$. Substituting this into Eq. 19.74 produces an equation for the *critical velocity.*

$$v_c = \sqrt{g d_c} \qquad 19.76$$

The expression for critical velocity also coincides with the expression for the velocity of a low-amplitude *surface wave* (*surge wave*) moving in a liquid of depth d_c. Since surface disturbances are transmitted as ripples upstream (and downstream) at velocity v_c, it is apparent that a surge wave will be stationary in a channel moving at the critical velocity. Such motionless waves are known as *standing waves.*

If the flow velocity is less than the surge wave velocity (for the actual depth), then a ripple can make its way upstream. If the flow velocity exceeds the surge wave velocity, the ripple will be swept downstream.

Example 19.8

500 ft^3/sec (14 m^3/s) of water flow in a 20 ft (6 m) wide rectangular channel. What are the (a) critical depth and (b) critical velocity?

SI Solution

(a) From Eq. 19.74, the critical depth is

$$d_c^3 = \frac{Q^2}{gw^2}$$

$$= \frac{\left(14 \frac{\text{m}^3}{\text{s}}\right)^2}{\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(6 \text{ m})^2}$$

$$d_c = 0.822 \text{ m}$$

(b) From Eq. 19.76, the critical velocity is

$$v_c = \sqrt{g d_c} = \sqrt{\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(0.822 \text{ m})}$$
$$= 2.84 \text{ m/s}$$

Customary U.S. Solution

(a) From Eq. 19.74, the critical depth is

$$d_c^3 = \frac{Q^2}{gw^2}$$

$$= \frac{\left(500 \frac{\text{ft}^3}{\text{sec}}\right)^2}{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(20 \text{ ft})^2}$$

$$d_c = 2.687 \text{ ft}$$

(b) From Eq. 19.76, the critical velocity is

$$v_c = \sqrt{g d_c} = \sqrt{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(2.687 \text{ ft})}$$
$$= 9.30 \text{ ft/sec}$$

26. CRITICAL FLOW AND CRITICAL DEPTH IN NONRECTANGULAR CHANNELS

For nonrectangular shapes (including trapezoidal channels), the critical depth can be found by trial and error from the following equation in which b is the surface width. To use Eq. 19.77, assume trial values of the critical depth, use them to calculate dependent quantities in the equation, and then verify the equality.

$$\frac{Q^2}{g} = \frac{A^3}{b} \quad \text{[nonrectangular]} \qquad 19.77$$

Equation 19.77 is particularly difficult to use with circular channels. Appendix 19.D is a convenient method of determining critical depth in circular channels.

27. FROUDE NUMBER

The dimensionless Froude number, Fr, is a convenient index of the flow regime. It can be used to determine whether the flow is subcritical or supercritical. d is the depth corresponding to velocity v. For a rectangular channel, $D_h = d$.

$$\mathrm{Fr} = \frac{\mathrm{v}}{\sqrt{gD_h}} \qquad 19.78$$

When the Froude number is less than one, the flow is subcritical; that is, the depth of flow is greater than the critical depth, and the velocity is less than the critical velocity.

For convenience, the Froude number can be written in terms of the flow rate per unit width.

$$\mathrm{Fr} = \frac{\frac{Q}{b}}{\sqrt{gd^3}} \quad \text{[rectangular]} \qquad 19.79$$

$$\mathrm{Fr} = \frac{\frac{Q}{b}}{\sqrt{g\left(\frac{A}{b}\right)^3}} \quad \text{[nonrectangular]} \qquad 19.80$$

When the Froude number is greater than one, the flow is supercritical. The depth is less than critical depth, and the flow velocity is greater than the critical velocity.

When the Froude number is equal to one, the flow is critical.[13]

The Froude number has another form. Dimensional analysis determines it to be v^2/gL, a form that is also used in analyzing similarity of models. Whether the derived form or the square root form is used can sometimes be determined by observing the form of the intended application. If the Froude number is squared (as it is in Eq. 19.81), then the square root form is probably intended. For open channel flow, the Froude number is always the square root of the derived form.

[13]The similarity of the Froude number to the Mach number used to classify gas flows is more than coincidental. Both bodies of knowledge employ similar concepts.

28. PREDICTING OPEN CHANNEL FLOW BEHAVIOR

Upon encountering a variation in the channel bottom, the behavior of an open channel flow is dependent on whether the flow is initially subcritical or supercritical. Open channel flow is governed by Eq. 19.81 in which the Froude number is the primary independent variable.

$$\frac{dd}{dx}(1 - \mathrm{Fr}^2) + \frac{dz}{dx} = 0 \qquad 19.81$$

The quantity dd/dx is the slope of the surface (i.e., it is the derivative of the depth with respect to the channel length). The quantity dz/dx is the slope of the channel bottom.

For an upward step, $dz/dx > 0$. If the flow is initially subcritical (i.e., $\mathrm{Fr} < 1$), then Eq. 19.81 requires that $dd/dx < 0$, a drop in depth.

This logic can be repeated for other combinations of the terms. Table 19.5 lists the various behaviors of open channel flow surface levels based on Eq. 19.81.

Table 19.5 *Surface Level Change Behavior*

initial flow	step up	step down
subcritical	surface drops	surface rises
supercritical	surface rises	surface drops

If $dz/dx = 0$ (i.e., a horizontal slope), then either the depth must be constant or the Froude number must be unity. The former case is obvious. The latter case predicts critical flow. Such critical flow actually occurs where the slope is horizontal over broad-crested weirs (see Fig. 19.17) and at the top of a rounded spillway. Since broad-crested weirs and spillways produce critical flow, they represent a class of controls on flow.

29. OCCURRENCES OF CRITICAL FLOW

The critical depth not only minimizes the energy of flow, but also maximizes the quantity flowing for a given cross section and slope. Critical flow is generally quite turbulent because of the large changes in energy that occur with small changes in elevation and depth. Critical depth flow is often characterized by successive water surface undulations over a very short stretch of channel.

For any given discharge and cross section, there is a unique slope that will produce and maintain flow at critical depth. Once d_c is known, this critical slope

can be found from the Manning equation. In all of the instances of critical depth, Eq. 19.67 can be used to calculate the actual velocity.

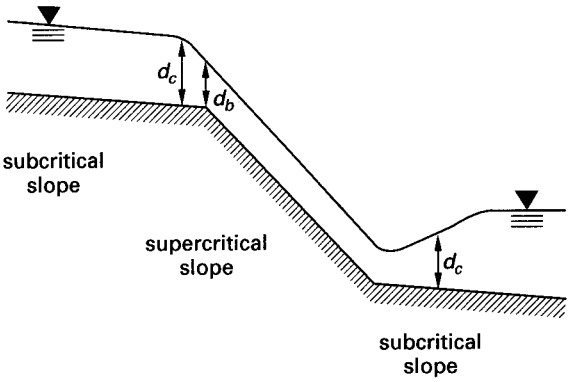


Figure 19.15 *Occurrence of Critical Depth*

Critical depth occurs at free outfall from a channel of mild slope. The occurrence is at the point of curvature inversion, just upstream from the brink. For mild slopes, the *brink depth* is approximately

$$d_b = 0.715 d_c \qquad 19.82$$

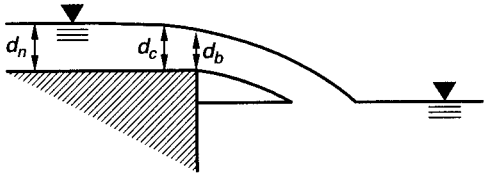

Figure 19.16 *Free Outfall*

Critical flow can occur across a broad-crested weir, as shown in Fig. 19.17.[14] With no obstruction to hold the water, it falls from the normal depth to the critical depth, but it can fall no more than that because there is no source to increase the specific energy (to increase the velocity). This is not a contradiction of the previous free outfall case where the brink depth is less than the critical depth. The flow curvatures in free outfall are a result of the constant gravitational acceleration.

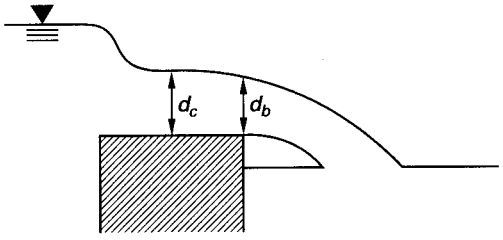

Figure 19.17 *Broad-Crested Weir*

[14]Figure 19.17 is an example of a *hydraulic drop*, the opposite of a hydraulic jump. A hydraulic drop can be recognized by the sudden decrease in depth over a short length of channel.

Critical depth can also occur when a channel bottom has been raised sufficiently to choke the flow. A raised channel bottom is essentially a broad-crested weir.

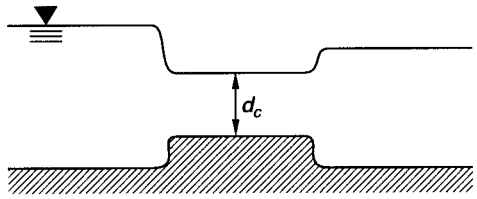

Figure 19.18 *Raised Channel Bottom with Choked Flow*

Example 19.9

At a particular point in an open rectangular channel ($n = 0.013$, $S = 0.002$, and $w = 10$ ft (3 m)), the flow is 250 ft^3/sec (7 m^3/s) and the depth is 4.2 ft (1.3 m).

(a) Is the flow tranquil, critical, or rapid?

(b) What is the normal depth?

(c) If the channel ends in a free outfall, what is the brink depth?

SI Solution

(a) From Eq. 19.74, the critical depth is

$$d_c = \left(\frac{Q^2}{gw^2}\right)^{\frac{1}{3}}$$

$$= \left(\frac{\left(7\ \frac{\text{m}^3}{\text{s}}\right)^2}{(3\ \text{m})^2\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}\right)^{\frac{1}{3}}$$

$$= 0.82\ \text{m}$$

Since the actual depth exceeds the critical depth, the flow is tranquil.

(b) From Eq. 19.13,

$$Q = \left(\frac{1.00}{n}\right) A R^{\frac{2}{3}} \sqrt{S}$$

$$R = \frac{A}{P}$$

$$= \frac{d_n(3\ \text{m})}{2d_n + 3\ \text{m}}$$

Substitute the expression for R into Eq. 19.13 and solve for d_n.

$$7\ \frac{\text{m}^3}{\text{s}} = \left(\frac{1.00}{0.013}\right) d_n(3\ \text{m}) \left(\frac{d_n(3\ \text{m})}{2d_n + 3\ \text{m}}\right)^{\frac{2}{3}} \sqrt{0.002}$$

By trial and error or a calculator's equation solver, $d_n = 0.97$ m. Since the actual and normal depths are different, the flow is nonuniform.

(c) From Eq. 19.82, the brink depth is

$$\begin{aligned} d_b &= 0.715 d_c = (0.715)(0.82 \text{ m}) \\ &= 0.59 \text{ m} \end{aligned}$$

Customary U.S. Solution

(a) From Eq. 19.74, the critical depth is

$$\begin{aligned} d_c &= \left(\frac{Q^2}{gw^2}\right)^{\frac{1}{3}} \\ &= \left(\frac{\left(250 \frac{\text{ft}^3}{\text{sec}}\right)^2}{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(10 \text{ ft})^2}\right)^{\frac{1}{3}} \\ &= 2.69 \text{ ft} \end{aligned}$$

Since the actual depth exceeds the critical depth, the flow is tranquil.

(b) From Eq. 19.13,

$$\begin{aligned} Q &= \left(\frac{1.49}{n}\right) A R^{\frac{2}{3}} \sqrt{S} \\ R &= \frac{A}{P} \\ &= \frac{d_n(10 \text{ ft})}{2d_n + 10 \text{ ft}} \end{aligned}$$

Substitute the expression for R into Eq. 19.13 and solve for d_n.

$$250 \frac{\text{ft}^3}{\text{sec}} = \left(\frac{1.49}{0.013}\right) d_n(10 \text{ ft}) \left(\frac{d_n(10 \text{ ft})}{2d_n + 10 \text{ ft}}\right)^{\frac{2}{3}} \sqrt{0.002}$$

By trial and error or a calculator's equation solver, $d_n = 3.1$ ft. Since the actual and normal depths are different, the flow is nonuniform.

(c) From Eq. 19.82, the brink depth is

$$\begin{aligned} d_b &= 0.715 d_c \\ &= (0.715)(2.69 \text{ ft}) \\ &= 1.92 \text{ ft} \end{aligned}$$

30. CONTROLS ON FLOW

If flow is subcritical, then a disturbance downstream will be able to affect the upstream conditions. Since the flow velocity is less than the critical velocity, a ripple will be able to propagate upstream to signal a change in the downstream conditions. Any object downstream that affects the flow rate, velocity, or depth upstream is known as a *downstream control.*

If a flow is supercritical, then a downstream obstruction will have no effect upstream, since disturbances cannot propagate upstream faster than the flow velocity. The only effect on supercritical flow is from an upstream obstruction. Such an obstruction is said to be an *upstream control.*

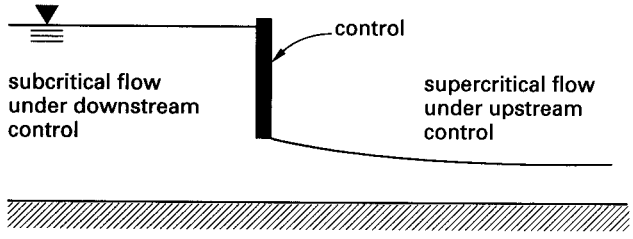

Figure 19.19 *Control on Flow*

In general, any feature that affects depth and discharge rates is known as a *control on flow.* Controls may consist of constructed control structures (weirs, gates, sluices, etc.), forced flow through critical depth (as in a free outfall), sudden changes of slope (which forces a hydraulic jump or hydraulic drop to the new normal depth), or free flow between reservoirs of different surface elevations. A downstream control may also be an upstream control, as Fig. 19.19 shows.

31. FLOW CHOKING

A channel feature that causes critical flow to occur is known as a *choke,* and the corresponding flow past the feature and downstream is known as *choked flow.*

In the case of vertical transitions (i.e., upward or downward steps in the channel bottom), choked flow will occur when the step size is equal to the difference between the upstream specific energy and the critical flow energy.

$$\Delta z = E_1 - E_c \quad \text{[choked flow]} \qquad 19.83$$

In the case of a rectangular channel, the maximum variation in channel bottom will be

$$\begin{aligned} \Delta z &= E_1 - \left(d_c + \frac{\text{v}_c^2}{2g}\right) \\ &= E_1 - \tfrac{3}{2} d_c \end{aligned} \qquad 19.84$$

The flow downstream from a choke point can be subcritical or supercritical, depending on the downstream conditions. If there is a downstream control, such as a sluice gate, the flow downstream will be subcritical. If there is additional gravitational acceleration (as with flow down the side of a dam spillway), then the flow will be supercritical.

32. VARIED FLOW

Accelerated flow occurs in any channel where the actual slope exceeds the friction loss per foot.

$$S_0 > \frac{h_f}{L} \qquad 19.85$$

Retarded flow occurs when the actual slope is less than the unit friction loss.

$$S_0 < \frac{h_f}{L} \qquad 19.86$$

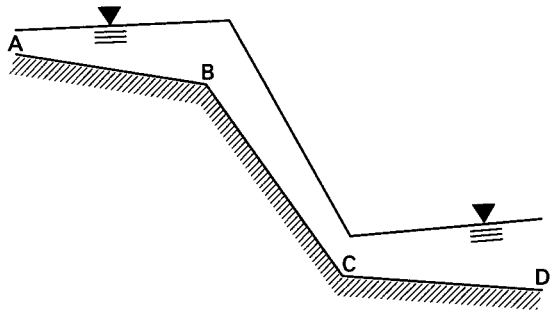

Figure 19.20 *Varied Flow*

In sections AB and CD of Fig. 19.20, the slopes are less than the energy gradient, so the flows are retarded. In section BC, the slope is greater than the energy gradient, so the velocity increases (i.e., the flow is accelerated). If section BC were long enough, the friction loss would eventually become equal to the accelerating energy and the flow would become uniform.

The distance between points of two known depths in accelerated or retarded flow can be determined from the average velocity. Equations 19.87 and 19.88 assume that the friction losses are the same for varied flow as for uniform flow.

$$S_{ave} = \left(\frac{n v_{ave}}{(R_{ave})^{\frac{2}{3}}}\right)^2 \qquad \text{[SI]} \qquad 19.87(a)$$

$$S_{ave} = \left(\frac{n v_{ave}}{1.49(R_{ave})^{\frac{2}{3}}}\right)^2 \qquad \text{[U.S.]} \qquad 19.87(b)$$

$$v_{ave} = \left(\frac{1.00}{n}\right)(R_{ave})^{\frac{2}{3}}\sqrt{S_{ave}} \qquad \text{[SI]} \qquad 19.88(a)$$

$$v_{ave} = \left(\frac{1.49}{n}\right)(R_{ave})^{\frac{2}{3}}\sqrt{S_{ave}} \qquad \text{[U.S.]} \qquad 19.88(b)$$

S is the slope of the energy gradient from Eq. 19.87, not the channel slope S_0. The usual method of finding the *depth profile* is to start at a point in the channel where d_2 and v_2 are known. Then, assume a depth d_1, find v_1 and S, and solve Eq. 19.89 for L. Repeat as needed.

$$L = \frac{\left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right)}{S - S_0} = \frac{E_1 - E_2}{S - S_0} \qquad 19.89$$

Example 19.10

How far from the point described in Ex. 19.9 will the depth be 4 ft (1.2 m)?

SI Solution

The difference between 1.3 m and 1.2 m is small, so a one-step calculation will probably be sufficient.

$$d_1 = 1.2 \text{ m}$$

$$v_1 = \frac{Q}{A} = \frac{7\ \frac{\text{m}^3}{\text{s}}}{(1.2\text{ m})(3\text{ m})} = 1.94 \text{ m/s}$$

$$E_1 = d_1 + \frac{v_1^2}{2g} = 1.2 \text{ m} + \frac{\left(1.94\ \frac{\text{m}}{\text{s}}\right)^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)} = 1.39 \text{ m}$$

$$R_1 = \frac{A_1}{P_1} = \frac{(1.2\text{ m})(3\text{ m})}{1.2\text{ m} + 3\text{ m} + 1.2\text{ m}} = 0.67 \text{ m}$$

$$d_2 = 1.3 \text{ m}$$

$$v_2 = \frac{7\ \frac{\text{m}^3}{\text{s}}}{(1.3\text{ m})(3\text{ m})} = 1.79 \text{ m/s}$$

$$E_2 = d_2 + \frac{v_2^2}{2g} = 1.3 \text{ m} + \frac{\left(1.79\ \frac{\text{m}}{\text{s}}\right)^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)} = 1.46 \text{ m}$$

$$R_2 = \frac{A_2}{P_2} = \frac{(1.3\text{ m})(3\text{ m})}{1.3\text{ m} + 3\text{ m} + 1.3\text{ m}} = 0.70 \text{ m}$$

$$v_{ave} = \tfrac{1}{2}(v_1 + v_2) = \left(\tfrac{1}{2}\right)\left(1.94\ \frac{\text{m}}{\text{s}} + 1.79\ \frac{\text{m}}{\text{s}}\right) = 1.865 \text{ m/s}$$

$$R_{ave} = \tfrac{1}{2}(R_1 + R_2) = \left(\tfrac{1}{2}\right)(0.70\text{ m} + 0.67\text{ m}) = 0.685 \text{ m}$$

From Eq. 19.87,

$$S = \left(\frac{n v_{ave}}{(R_{ave})^{\frac{2}{3}}}\right)^2 = \left(\frac{(0.013)\left(1.865\ \frac{\text{m}}{\text{s}}\right)}{(1.00)(0.685\text{ m})^{\frac{2}{3}}}\right)^2 = 0.000973$$

From Eq. 19.89,

$$L = \frac{E_1 - E_2}{S - S_0} = \frac{1.39\text{ m} - 1.46\text{ m}}{0.000973 - 0.002} = 68.2 \text{ m}$$

Customary U.S. Solution

The difference between 4 ft and 4.2 ft is small, so a one-step calculation will probably be sufficient.

$$d_1 = 4 \text{ ft}$$

$$v_1 = \frac{Q}{A} = \frac{250\ \frac{\text{ft}^3}{\text{sec}}}{(4\text{ ft})(10\text{ ft})} = 6.25\ \text{ft/sec}$$

$$E_1 = d_1 + \frac{v_1^2}{2g}$$

$$= 4\text{ ft} + \frac{\left(6.25\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}$$

$$= 4.607\text{ ft}$$

$$R_1 = \frac{A_1}{P_1} = \frac{(14\text{ ft})(10\text{ ft})}{4\text{ ft} + 10\text{ ft} + 4\text{ ft}}$$

$$= 2.22\text{ ft}$$

$$d_2 = 4.2\text{ ft}$$

$$v_2 = \frac{250\ \frac{\text{ft}^3}{\text{sec}}}{(4.2\text{ ft})(10\text{ ft})} = 5.95\ \text{ft/sec}$$

$$E_2 = d_2 + \frac{v_2^2}{2g} = 4.2\text{ ft} + \frac{\left(5.95\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}$$

$$= 4.75\text{ ft}$$

$$R_2 = \frac{A_2}{P_2} = \frac{(4.2\text{ ft})(10\text{ ft})}{4.2\text{ ft} + 10\text{ ft} + 4.2\text{ ft}} = 2.28\text{ ft}$$

$$v_{ave} = \tfrac{1}{2}(v_1 + v_2)$$

$$= \left(\tfrac{1}{2}\right)\left(6.25\ \frac{\text{ft}}{\text{sec}} + 5.95\ \frac{\text{ft}}{\text{sec}}\right) = 6.1\ \text{ft/sec}$$

$$R_{ave} = \tfrac{1}{2}(R_1 + R_2)$$

$$= \left(\tfrac{1}{2}\right)(2.22\text{ ft} + 2.28\text{ ft}) = 2.25\text{ ft}$$

From Eq. 19.87,

$$S = \left(\frac{n v_{ave}}{1.49 (R_{ave})^{\frac{2}{3}}}\right)^2$$

$$= \left(\frac{(0.013)\left(6.1\ \frac{\text{ft}}{\text{sec}}\right)}{(1.49)(2.25\text{ ft})^{\frac{2}{3}}}\right)^2$$

$$= 0.000965$$

From Eq. 19.89,

$$L = \frac{E_1 - E_2}{S - S_0}$$

$$= \frac{4.607\text{ ft} - 4.75\text{ ft}}{0.000965 - 0.002} = 138\text{ ft}$$

33. HYDRAULIC JUMP

If water is introduced at high (supercritical) velocity to a section of slow-moving (subcritical) flow (as in section C in Fig. 19.20), the velocity will be reduced rapidly over a short length of channel. The abrupt rise in the water surface is known as a *hydraulic jump*. The increase in depth is always from below the critical depth to above the critical depth.[15] The depths on either side of the hydraulic jump are known as *conjugate depths*. The conjugate depths and the relationship between them are as follows.

$$d_1 = -\tfrac{1}{2}d_2 + \sqrt{\frac{2v_2^2 d_2}{g} + \frac{d_2^2}{4}} \qquad 19.90$$

$$d_2 = -\tfrac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \qquad 19.91$$

$$\frac{d_2}{d_1} = \tfrac{1}{2}\left(\sqrt{1 + 8(\text{Fr}_1)^2} - 1\right) \qquad 19.92(a)$$

$$\frac{d_1}{d_2} = \tfrac{1}{2}\left(\sqrt{1 + 8(\text{Fr}_2)^2} - 1\right) \qquad 19.92(b)$$

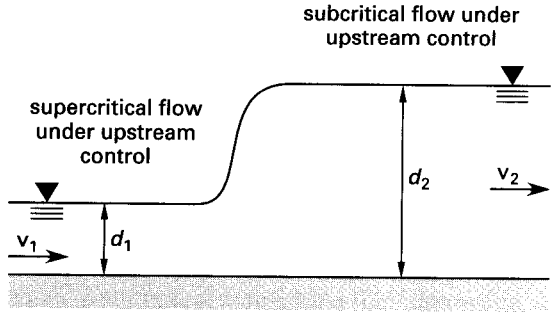

Figure 19.21 *Conjugate Depths*

If the depths d_1 and d_2 are known, then the upstream velocity can be found from Eq. 19.93.

$$v_1^2 = \left(\frac{g d_2}{2 d_1}\right)(d_1 + d_2) \qquad 19.93$$

Conjugate depths are not the same as alternate depths. Alternate depths are derived from the conservation of energy equation (i.e., a variation of the Bernoulli equation). Conjugate depths (calculated in Eqs. 19.90 through 19.92) are derived from a conservation of momentum equation. Conjugate depths are calculated only when there has been an abrupt energy loss such as occurs in a hydraulic jump or drop.

Hydraulic jumps have practical applications in the design of stilling basins. Stilling basins are designed to intentionally reduce energy of flow through hydraulic jumps. In the case of a concrete apron at the bottom of

[15]This provides a way of determining if a hydraulic jump can occur in a channel. If the original depth is above the critical depth, the flow is already subcritical. Therefore, a hydraulic jump cannot form. Only a hydraulic drop could occur.

a dam spillway, the apron friction is usually low, and the water velocity will decrease only gradually. However, supercritical velocities can be reduced to much slower velocities by having the flow cross a series of baffles on the channel bottom.

The specific energy lost in the jump is the energy lost per pound of water flowing.

$$\Delta E = \left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right) \qquad 19.94$$

Evaluation of hydraulic jumps in stilling basins starts by determining the depth at the toe. The depth of flow at the toe of a spillway is found from an energy balance. Neglecting friction, the total energy at the toe equals the total upstream energy before the spillway. The total upstream energy before the spillway is

$$E_{\text{upstream}} = E_{\text{toe}} \qquad 19.95$$

$$y_{\text{crest}} + H + \frac{v^2}{2g} = d_{\text{toe}} + \frac{v_{\text{toe}}^2}{2g} \qquad 19.96$$

The upstream velocity, v, is the velocity before the spillway (which is essentially zero), not the velocity over the brink. If the brink depth is known, the velocity over the brink can be used with the continuity equation to calculate the upstream velocity, but the velocity over the brink should not be used to determine total energy since $d_{\text{brink}} \neq H$.

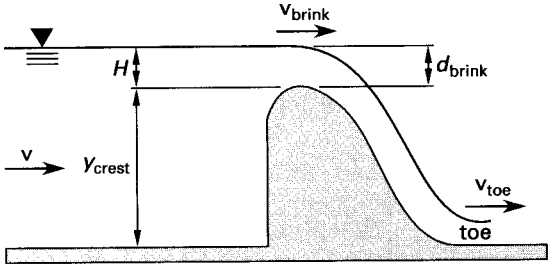

Figure 19.22 *Total Energy Upstream of a Spillway*

If water is drained quickly from the apron so that the tailwater depth is small or zero, no hydraulic jump will form. This is because the tailwater depth is already less than the critical depth.

A hydraulic jump will form along the apron at the bottom of the spillway when the actual tailwater depth equals the conjugate depth d_2 corresponding to the depth at the toe. That is, the jump is located at the toe when $d_2 = d_{\text{tailwater}}$, where d_2 and $d_1 = d_{\text{toe}}$ are conjugate depths. The tailwater and toe depths are implicitly the conjugate depth. This is shown in Fig. 19.23(a) and is the proper condition for energy dissipation in a stilling basin.

When the actual tailwater depth is less than the conjugate depth d_2 corresponding to d_{toe}, but still greater than the critical depth, flow will continue along the apron until the depth increases to conjugate depth d_1 corresponding to the actual tailwater depth. This is shown in Fig. 19.23(b). A hydraulic jump will form at that point to increase the depth to the tailwater depth. (Another way of saying this is that the hydraulic jump moves downstream from the toe.) This is an undesirable condition, since the location of the jump is often inadequately protected from scour.

If the tailwater depth is greater than the conjugate depth corresponding to the depth at the toe, as in Fig. 19.23(c), the hydraulic jump may occur up on the spillway, or it may be completely submerged (i.e., it will not occur at all).

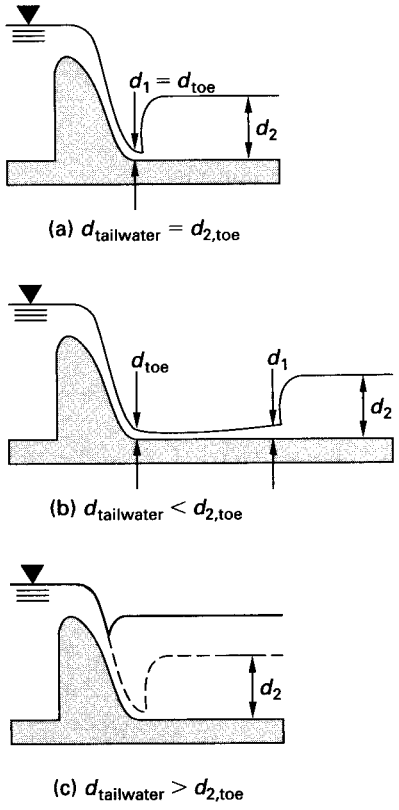

Figure 19.23 *Hydraulic Jump to Reach Tailwater Level*

Example 19.11

A hydraulic jump is produced at a point in a 10 ft (3 m) wide channel where the depth is 1 ft (0.3 m). The flow rate is 200 ft^3/sec (5.7 m^3/s). (a) What is the depth after the jump? (b) What is the total power dissipated?

SI Solution

(a)
$$v_1 = \frac{Q}{A} = \frac{5.7\ \frac{\text{m}^3}{\text{s}}}{(3\ \text{m})(0.3\ \text{m})}$$
$$= 6.33\ \text{m/s}$$

From Eq. 19.91,

$$\begin{aligned} d_2 &= -\tfrac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \\ &= -\left(\tfrac{1}{2}\right)(0.3\ \text{m}) \\ &\quad + \sqrt{\frac{(2)\left(6.33\ \frac{\text{m}}{\text{s}}\right)^2 (0.3\ \text{m})}{9.81\ \frac{\text{m}}{\text{s}^2}} + \frac{(0.3\ \text{m})^2}{4}} \\ &= 1.42\ \text{m} \end{aligned}$$

(b) The mass flow rate is

$$\begin{aligned} \dot{m} &= \left(5.7\ \frac{\text{m}^3}{\text{s}}\right)\left(1000\ \frac{\text{kg}}{\text{m}^3}\right) \\ &= 5700\ \text{kg/s} \end{aligned}$$

The velocity after the jump is

$$\begin{aligned} v_2 &= \frac{Q}{A_2} = \frac{5.7\ \frac{\text{m}^3}{\text{s}}}{(3\ \text{m})(1.42\ \text{m})} \\ &= 1.33\ \text{m/s} \end{aligned}$$

From Eq. 19.94, the change in specific energy is

$$\begin{aligned} \Delta E &= \left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right) \\ &= \left(0.3\ \text{m} + \frac{\left(6.33\ \frac{\text{m}}{\text{s}}\right)^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}\right) \\ &\quad - \left(1.423\ \text{m} + \frac{\left(1.33\ \frac{\text{m}}{\text{s}}\right)^2}{(2)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)}\right) \\ &= 0.83\ \text{m} \end{aligned}$$

The total power dissipated is

$$\begin{aligned} P &= \dot{m}g\Delta E \\ &= \left(5700\ \frac{\text{kg}}{\text{s}}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)\left(\frac{0.83\ \text{m}}{1000\ \frac{\text{W}}{\text{kW}}}\right) \\ &= 46.4\ \text{kW} \end{aligned}$$

Customary U.S. Solution

(a)
$$\begin{aligned} v_1 &= \frac{Q}{A} = \frac{200\ \frac{\text{ft}^3}{\text{sec}}}{(10\ \text{ft})(1\ \text{ft})} \\ &= 20\ \text{ft/sec} \end{aligned}$$

From Eq. 19.91,

$$\begin{aligned} d_2 &= -\tfrac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \\ &= -\left(\tfrac{1}{2}\right)(1\ \text{ft}) + \sqrt{\frac{(2)\left(20\ \frac{\text{ft}}{\text{sec}}\right)^2 (1\ \text{ft})}{32.2\ \frac{\text{ft}}{\text{sec}^2}} + \frac{(1\ \text{ft})^2}{4}} \\ &= 4.51\ \text{ft} \end{aligned}$$

(b) The mass flow rate is

$$\begin{aligned} \dot{m} &= \left(200\ \frac{\text{ft}^3}{\text{sec}}\right)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right) \\ &= 12{,}480\ \text{lbm/sec} \end{aligned}$$

The velocity after the jump is

$$\begin{aligned} v_2 &= \frac{Q}{A_2} = \frac{200\ \frac{\text{ft}^3}{\text{sec}}}{(10\ \text{ft})(4.51\ \text{ft})} \\ &= 4.43\ \text{ft/sec} \end{aligned}$$

From Eq. 19.94, the change in specific energy is

$$\begin{aligned} \Delta E &= \left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right) \\ &= \left(1\ \text{ft} + \frac{\left(20\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}\right) \\ &\quad - \left(4.51\ \text{ft} + \frac{\left(4.43\ \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)}\right) \\ &= 2.4\ \text{ft} \end{aligned}$$

The total power dissipated is

$$\begin{aligned} P &= \frac{\dot{m}g\Delta E}{g_c} \\ &= \frac{\left(12{,}480\ \frac{\text{lbm}}{\text{sec}}\right)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)(2.4\ \text{ft})}{\left(32.2\ \frac{\text{ft-lbm}}{\text{lbf-sec}^2}\right)\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)} \\ &= 54.5\ \text{hp} \end{aligned}$$

34. LENGTH OF HYDRAULIC JUMP

For practical stilling basin design, it is helpful to have an estimate of the length of the hydraulic jump. Lengths of hydraulic jumps are difficult to measure because of the

difficulty in defining the endpoints of the jumps. However, the length of the jump, L, varies within the limits of $5 < L/d_2 < 6.5$, in which d_2 is the conjugate depth after the jump. Where greater accuracy is warranted, Table 19.6 can be used. This table correlates the length of the jump to the upstream Froude number.

Table 19.6 *Approximate Lengths of Hydraulic Jumps*

$N_{Fr,1}$	$\frac{L}{d_2}$
3	5.25
4	5.8
5	6.0
6	6.1
7	6.15
8	6.15

35. HYDRAULIC DROP

A *hydraulic drop* is the reverse of a hydraulic jump. If water is introduced at low (subcritical) velocity to a section of fast-moving (supercritical) flow, the velocity will be increased rapidly over a short length of channel. The abrupt drop in the water surface is known as a hydraulic drop. The decrease in depth is always from above the critical depth to below the critical depth.

Water flowing over a spillway and down a long, steep chute typically experiences a hydraulic drop, with critical depth occurring just before the brink. This is illustrated in Fig. 19.16.

The depths on either side of the hydraulic drop are the *conjugate depths*, which are determined from Eqs. 19.90 and 19.91. The equations for calculating specific energy and power changes are the same for hydraulic jumps and drops.

36. ERODIBLE CHANNELS

Given an appropriate value of the Manning coefficient, the analysis of channels constructed of erodible materials is similar to that for concrete or pipe channels.

However, for design problems, maximum velocities and permissible side slopes must also be considered. The present state of knowledge is not sufficiently sophisticated to allow for precise designs. The usual uniform flow equations are insufficient because the stability of erodible channels is dependent on the properties of the channel material rather than on the hydraulics of flow. Two methods of design exist: (a) the tractive force method and (b) the simpler maximum permissible velocity method. Maximum velocities that should be used with erodible channels are given in Table 19.7.

Table 19.7 *Suggested Maximum Velocities*

	maximum permissible velocities (ft/sec)		
soil type or lining (earth; no vegetation)	clear water	water carrying fine silts	water carrying sand and gravel
fine sand (noncolloidal)	1.5	2.5	1.5
sandy loam (noncolloidal)	1.7	2.5	2.0
silt loam (noncolloidal)	2.0	3.0	2.0
ordinary firm loam	2.5	3.5	2.2
volcanic ash	2.5	3.5	2.0
fine gravel	2.5	5.0	3.7
stiff clay (very colloidal)	3.7	5.0	3.0
graded, loam to cobbles (noncolloidal)	3.7	5.0	5.0
graded, silt to cobbles (colloidal)	4.0	5.5	5.0
alluvial silts (noncolloidal)	2.0	3.5	2.0
alluvial silts (colloidal)	3.7	5.0	3.0
coarse gravel (noncolloidal)	4.0	6.0	6.5
cobbles and shingles	5.0	5.5	6.5
shales and hard pans	6.0	6.0	5.0

(Multiply ft/sec by 0.3 to obtain m/s.)

The sides of the channel should not have a slope exceeding the natural angle of repose for the material used. Although there are other factors that determine the maximum permissible side slope, Table 19.8 lists some guidelines.

Table 19.8 *Recommended Side Slopes*

type of channel	side slope (horizontal:vertical)
firm rock	vertical to $\frac{1}{4}$:1
concrete-lined stiff clay	$\frac{1}{2}$:1
fissured rock	$\frac{1}{2}$:1
firm earth with stone lining	1:1
firm earth, large channels	1:1
firm earth, small channels	$1\frac{1}{2}$:1
loose, sandy earth	2:1
sandy, porous loam	3:1

37. CULVERTS[16]

A *culvert* is a pipe that carries water under or through some feature (usually a road or highway) that would otherwise block the flow of water. For example, highways are often built at right angles to ravines draining hillsides and other watersheds. Culverts under the highway keep the construction fill from blocking the natural runoff.

Culverts are classified according to which of their ends controls the discharge capacity: inlet control or outlet control. If water can flow through and out of the culvert faster than it can enter, the culvert is under *inlet control.* If water can flow into the culvert faster than it can flow through and out, the culvert is under *outlet control.* Culverts under inlet control will always flow partially full. Culverts under outlet control can flow either partially full or full.

The culvert length is one of the most important factors in determining whether the culvert flows full. A culvert may be known as "hydraulically long" if it runs full and "hydraulically short" if it does not.[17]

All culvert design theory is closely dependent on energy conservation. However, due to the numerous variables involved, no single formula or procedure can be used to design a culvert. Culvert design is often an empirical, trial-and-error process. Figure 19.24 illustrates some of the important variables that affect culvert performance.

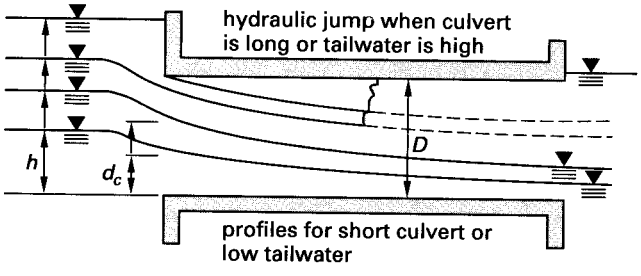

Figure 19.24 *Flow Profiles in Culvert Design*

A culvert can operate with its entrance partially or totally submerged. Similarly, the exit can be partially or totally submerged, or it can have free outfall. The upstream head, h, is the water surface level above the lowest part of the culvert barrel, known as the *invert.*[18]

In Fig. 19.24, the three lowermost surface level profiles are of the type that would be produced with inlet control. Such a situation can occur if the culvert is short and the slope is steep. Flow at the entrance is critical as the water falls over the brink. Since critical flow occurs, the flow is choked and the inlet controls the flow rate. Downstream variations cannot be transmitted past the critical section.

If the tailwater covers the culvert exit completely (i.e., a submerged exit), the culvert will be full at that point, even though the inlet control forces the culvert to be only partially full at the inlet. The transition from partially full to totally full occurs in a hydraulic jump, the location of which depends on the flow resistance and water levels. If the flow resistance is very high, or if the headwater and tailwater levels are high enough, the jump will occur close to or at the entrance.

If the flow in a culvert is full for its entire length, then the flow is under outlet control. The discharge will be a function of the differences in tailwater and headwater levels, as well as the flow resistance along the barrel length.

38. DETERMINING TYPE OF CULVERT FLOW

For convenience, culvert flow is classified into six different types on the basis of the type of control, the steepness of the barrel, the relative tailwater and headwater heights, and in some cases, the relationship between critical depth and culvert size. These parameters are quantified through the use of the ratios in Table 19.9.[19] The six types are illustrated in Fig. 19.25. Identification of the type of flow beyond the guidelines in Table 19.9 requires a trial-and-error procedure.

In the following cases, several variables appear repeatedly. C_d is the discharge coefficient, a function of the barrel inlet geometry. Orifice data can be used to approximate the discharge coefficient when specific information is unavailable. v_1 is the average velocity of the water approaching the culvert entrance and is often insignificant. The velocity-head coefficient, α, also called the *Coriolis coefficient,* accounts for a nonuniform distribution of velocities over the channel section. However, it represents only a second-order correction and is normally neglected. d_c is the critical depth, which may not correspond to the actual depth of flow. (It must be calculated from the flow conditions.) h_f is the friction loss in the identified section. For culverts flowing full, the friction loss can be found in the usual manner developed for pipe flow: from the Darcy formula and the Moody friction factor chart. For partial flow, the Manning equation and its variations (e.g., Eq. 19.30) can also be used. The Manning equation is particularly useful since it eliminates the need for trial-and-error solutions. The friction head loss between sections 1 and 2, for example, can be calculated from Eq. 19.97.

$$h_{f,1\text{-}2} = \frac{LQ^2}{K_1 K_2} \qquad 19.97$$

[16]The methods of culvert flow analysis in this chapter are based on *Measurement of Peak Discharge at Culverts by Indirect Methods,* U.S. Department of the Interior (1968).

[17]Proper design of culvert entrances can reduce the importance of length on culvert filling.

[18]The highest part of the culvert barrel is known as the *soffit* or *crown.*

[19]The six cases presented here do not exhaust the various possibilities for entrance and exit control. Culvert design is complicated by this multiplicity of possible flows. Since only the easiest problems can be immediately categorized as one of the six cases, each situation needs to be carefully evaluated.

$$K = \left(\frac{1.00}{n}\right) R^{\frac{2}{3}} A \quad \text{[SI]} \qquad 19.98(a)$$

$$K = \left(\frac{1.49}{n}\right) R^{\frac{2}{3}} A \quad \text{[U.S.]} \qquad 19.98(b)$$

The total hydraulic head available, H, is divided between the velocity head in the culvert, the entrance loss (if considered), and the friction.

$$H = \frac{v^2}{2g} + k_e\left(\frac{v^2}{2g}\right) + \frac{v^2 n^2 L}{R^{\frac{4}{3}}} \quad \text{[SI]} \qquad 19.99(a)$$

$$H = \frac{v^2}{2g} + k_e\left(\frac{v^2}{2g}\right) + \frac{v^2 n^2 L}{2.21 R^{\frac{4}{3}}} \quad \text{[U.S.]} \qquad 19.99(b)$$

Equation 19.99 can be solved directly for the velocity. Equation 19.100 is valid for culverts of any shape.

$$v = \sqrt{\frac{H}{\frac{1+k_e}{2g} + \frac{n^2 L}{R^{\frac{4}{3}}}}} \quad \text{[SI]} \qquad 19.100(a)$$

$$v = \sqrt{\frac{H}{\frac{1+k_e}{2g} + \frac{n^2 L}{2.21 R^{\frac{4}{3}}}}} \quad \text{[U.S.]} \qquad 19.100(b)$$

Table 19.9 *Culvert Flow Classification Parameters*

flow type	$\frac{h_1 - z}{D}$	$\frac{h_4}{h_c}$	$\frac{h_4}{D}$	culvert slope	barrel flow	location of control	kind of control
1	< 1.5	< 1.0	≤ 1.0	steep	partial	inlet	critical depth
2	< 1.5	< 1.0	≤ 1.0	mild	partial	outlet	critical depth
3	< 1.5	> 1.0	≤ 1.0	mild	partial	outlet	backwater
4	> 1.0		> 1.0	any	full	outlet	backwater
5	≥ 1.5		≤ 1.0	any	partial	inlet	entrance geometry
6	≥ 1.5		≤ 1.0	any	full	outlet	entrance and barrel geometry

Figure 19.25 *Culvert Flow Classifications*

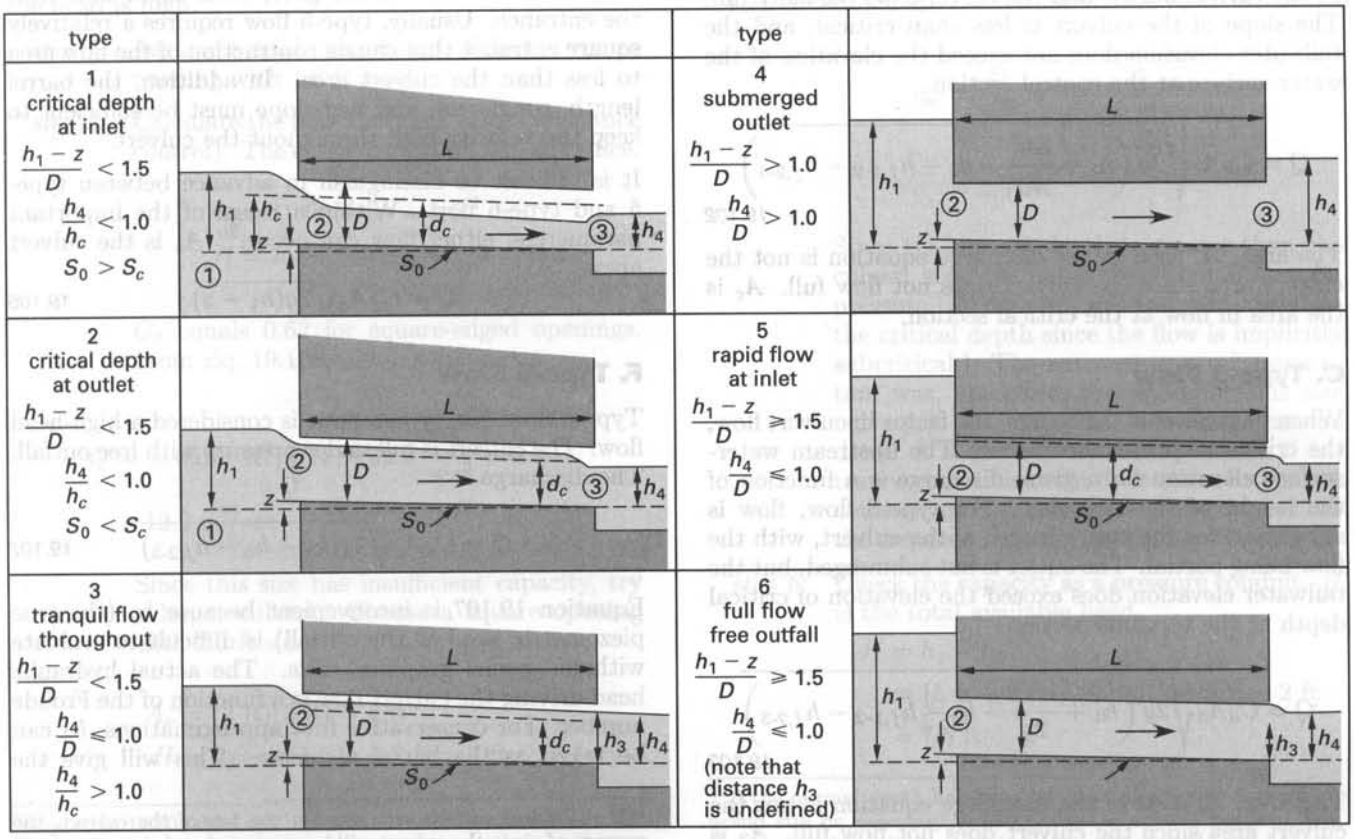

Table 19.10 Minor Entrance Loss Coefficients

k_e	condition of entrance
0.08	smooth, tapered
0.10	flush concrete groove
0.10	flush concrete bell
0.15	projecting concrete groove
0.15	projecting concrete bell
0.50	flush, square-edged
0.90	projecting, square-edged

A. Type-1 Flow

Water passes through the critical depth near the culvert entrance, and the culvert flows partially full. The slope of the culvert barrel is greater than the critical slope, and the tailwater elevation is less than the elevation of the water surface at the control section.

The discharge is

$$Q = C_d A_c \sqrt{2g\left(h_1 - z + \frac{\alpha v_1^2}{2g} - d_c - h_{f,1\text{-}2}\right)} \qquad 19.101$$

The area, A, used in the discharge equation is not the culvert area since the culvert does not flow full. A_c is the area in flow at the critical section.

B. Type-2 Flow

As in type-1 flow, flow passes through the critical depth at the culvert outlet, and the barrel flows partially full. The slope of the culvert is less than critical, and the tailwater elevation does not exceed the elevation of the water surface at the control section.

$$Q = C_d A_c \sqrt{2g\left(h_1 + \frac{\alpha v_1^2}{2g} - d_c - h_{f,1\text{-}2} - h_{f,2\text{-}3}\right)} \qquad 19.102$$

The area, A, used in the discharge equation is not the culvert area since the culvert does not flow full. A_c is the area in flow at the critical section.

C. Type-3 Flow

When backwater is the controlling factor in culvert flow, the critical depth cannot occur. The upstream water-surface elevation for a given discharge is a function of the height of the tailwater. For type-3 flow, flow is subcritical for the entire length of the culvert, with the flow being partial. The outlet is not submerged, but the tailwater elevation does exceed the elevation of critical depth at the terminal section.

$$Q = C_d A_3 \sqrt{2g\left(h_1 + \frac{\alpha v_1^2}{2g} - h_3 - h_{f,1\text{-}2} - h_{f,2\text{-}3}\right)} \qquad 19.103$$

The area, A, used in the discharge equation is not the culvert area since the culvert does not flow full. A_3 is the area in flow at numbered section 3 (i.e., the exit).

D. Type-4 Flow

As in type-3 flow, the backwater elevation is the controlling factor in this case. Critical depth cannot occur, and the upstream water surface elevation for a given discharge is a function of the tailwater elevation. Discharge is independent of barrel slope. The culvert is submerged at both the headwater and the tailwater. No differentiation between low head and high head is made for this case. If the velocity head at section 1 (the entrance), the entrance friction loss, and the exit friction loss are neglected, the discharge can be calculated. A_o is the culvert area.

$$Q = C_d A_o \sqrt{2g\left(\frac{h_1 - h_4}{1 + \frac{29 C_d^2 n^2 L}{R^{\frac{4}{3}}}}\right)} \qquad 19.104$$

The complicated term in the denominator corrects for friction. For rough estimates and for culverts less than 50 ft long, the friction loss can be ignored.

$$Q = C_d A_o \sqrt{2g(h_1 - h_4)} \qquad 19.105$$

E. Type-5 Flow

Partially full flow under a high head is classified as type-5 flow. The flow pattern is similar to the flow downstream from a sluice gate, with rapid flow near the entrance. Usually, type-5 flow requires a relatively square entrance that causes contraction of the flow area to less than the culvert area. In addition, the barrel length, roughness, and bed slope must be sufficient to keep the velocity high throughout the culvert.

It is difficult to distinguish in advance between type-5 and type-6 flow. Within a range of the important parameters, either flow can occur.[20] A_o is the culvert area.

$$Q = C_d A_o \sqrt{2g(h_1 - z)} \qquad 19.106$$

F. Type-6 Flow

Type-6 flow, like type-5 flow, is considered a high-head flow. The culvert is full under pressure with free outfall. The discharge is

$$Q = C_d A_o \sqrt{2g(h_1 - h_3 - h_{f,2\text{-}3})} \qquad 19.107$$

Equation 19.107 is inconvenient because h_3 (the true piezometric head at the outfall) is difficult to evaluate without special graphical aids. The actual hydraulic head driving the culvert flow is a function of the Froude number. For conservative first approximations, h_3 can be taken as the barrel diameter. This will give the

[20] If the water surface ever touches the top of the culvert, the passage of air in the culvert will be prevented and the culvert will flow full everywhere. This is type-6 flow.

minimum hydraulic head. In reality, h_3 varies from somewhat less than half the barrel diameter to the full diameter.

If h_3 is taken as the barrel diameter, the total hydraulic head ($H = h_1 - h_3$) will be split between the velocity head and friction. In that case, Eq. 19.100 can be used to calculate the velocity. The discharge is easily calculated from Eq. 19.108.[21] A_o is the culvert area.

$$Q = A_o \mathrm{v} \qquad 19.108$$

Example 19.12

Size a square culvert with an entrance fluid level 5 ft above the barrel top and a free exit to operate with the following characteristics:

$$\begin{aligned} \text{slope} &= 0.01 \\ \text{length} &= 250 \text{ ft} \\ \text{capacity} &= 45 \text{ ft}^3/\text{sec} \\ n &= 0.013 \end{aligned}$$

Solution

Since the h_1 dimension is measured from the culvert invert, it is difficult to classify the type of flow at this point. However, either type 5 or type 6 is likely since the head is high.

step 1: Assume a trial culvert size. Select a square opening with 1.0 ft sides.

step 2: Calculate the flow assuming case 5 (entrance control). The entrance will act like an orifice.

$$\begin{aligned} A_o &= (1 \text{ ft})(1 \text{ ft}) = 1 \text{ ft}^2 \\ H &= h_1 - z = 5 \text{ ft} + 1 \text{ ft} = 6 \text{ ft} \end{aligned}$$

C_d equals 0.62 for square-edged openings. From Eq. 19.106,

$$\begin{aligned} Q &= (0.62)(1 \text{ ft}^2)\sqrt{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(6 \text{ ft})} \\ &= 12.2 \text{ ft}^3/\text{sec} \end{aligned}$$

Since this size has insufficient capacity, try a larger culvert. Choose a square opening with 2.0 ft sides.

$$\begin{aligned} A_o &= (2 \text{ ft})(2 \text{ ft}) = 4 \text{ ft}^2 \\ H &= h_1 - z = 5 \text{ ft} + 2 \text{ ft} = 7 \text{ ft} \end{aligned}$$

$$\begin{aligned} Q &= C_d A_o \sqrt{2g(h_1 - z)} \\ &= (0.62)(4 \text{ ft}^2)\sqrt{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(7 \text{ ft})} \\ &= 52.7 \text{ ft}^3/\text{sec} \end{aligned}$$

step 3: Begin checking the entrance control assumption by calculating the maximum hydraulic radius. The upper surface of the culvert is not wetted because the flow is entrance-controlled. The hydraulic radius is maximum at the entrance.

$$\begin{aligned} R &= \frac{A_o}{P} \\ &= \frac{4 \text{ ft}^2}{2 \text{ ft} + 2 \text{ ft} + 2 \text{ ft}} \\ &= 0.667 \text{ ft} \end{aligned}$$

step 4: Calculate the velocity using the Manning equation for open channel flow. Since the hydraulic radius is maximum, the velocity will also be maximum.

$$\begin{aligned} \mathrm{v} &= \frac{1.49}{n} R^{\frac{2}{3}} \sqrt{S} \\ &= \left(\frac{1.49}{0.013}\right)(0.667 \text{ ft})^{\frac{2}{3}} \sqrt{0.01} \\ &= 8.75 \text{ ft/sec} \end{aligned}$$

step 5: Calculate the normal depth, d_n.

$$\begin{aligned} d_n &= \frac{Q}{\mathrm{v}w} = \frac{45 \frac{\text{ft}^3}{\text{sec}}}{\left(8.75 \frac{\text{ft}}{\text{sec}}\right)(2 \text{ ft})} \\ &= 2.57 \text{ ft} \end{aligned}$$

Since the normal depth is greater than the culvert size, the culvert will flow full under pressure. (It was not necessary to calculate the critical depth since the flow is implicitly subcritical.) The entrance control assumption was, therefore, not valid for this size culvert.[22] At this point, two things can be done: A larger culvert can be chosen if entrance control is desired, or the solution can continue by checking to see if the culvert has the required capacity as a pressure conduit.

step 6: Check the capacity as a pressure conduit. H is the total available head.

$$\begin{aligned} H &= h_1 - h_3 \\ &= \big(5 \text{ ft} + 2 \text{ ft} + (0.01)(250 \text{ ft})\big) - 2 \text{ ft} \\ &= 7.5 \text{ ft} \end{aligned}$$

[21] Equation 19.108 does not include the discharge coefficient. Velocity, v, when calculated from Eq. 19.100, is implicitly the velocity in the barrel.

[22] If the normal depth had been less than the barrel diameter, it would still be necessary to determine the critical depth of flow. If the normal depth was less than the critical depth, the entrance control assumption would have been valid.

step 7: Since the pipe is flowing full, the hydraulic radius is

$$R = \frac{A}{P} = \frac{4\ \text{ft}^2}{8\ \text{ft}} = 0.5\ \text{ft}$$

step 8: Equation 19.100 can be used to calculate the flow velocity. Since the culvert has a square-edged entrance, a loss coefficient of $k_e = 0.5$ is used. However, this does not greatly affect the velocity.

$$\text{v} = \sqrt{\frac{H}{\frac{1+k_e}{2g} + \frac{n^2 L}{2.21R^{\frac{4}{3}}}}}$$

$$= \sqrt{\frac{7.5\ \text{ft}}{\frac{1+0.5}{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}}\right)} + \frac{(0.013)^2(250\ \text{ft})}{(2.21)(0.5\ \text{ft})^{\frac{4}{3}}}}}$$

$$= 10.24\ \text{ft/sec}$$

step 9: Check the capacity.

$$Q = \text{v}A_o$$

$$= \left(10.24\ \frac{\text{ft}}{\text{sec}}\right)(4\ \text{ft}^2)$$

$$= 40.96\ \text{ft}^3/\text{sec}$$

The culvert size is not acceptable since its discharge under the maximum head does not have a capacity of 45 ft^3/sec.

step 10: Repeat from step 2, trying a larger-size culvert. With a 2.5 ft side, the following values are obtained.

$$A_o = (2.5\ \text{ft})(2.5\ \text{ft}) = 6.25\ \text{ft}^2$$

$$H = 5\ \text{ft} + 2.5\ \text{ft} = 7.5\ \text{ft}$$

$$Q = (0.62)(6.25\ \text{ft}^2) \times \sqrt{(2)\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)(7.5\ \text{ft})}$$

$$= 85.2\ \text{ft}^3/\text{sec}$$

$$R = \frac{6.25\ \text{ft}^2}{7.5\ \text{ft}} = 0.833\ \text{ft}$$

$$\text{v} = \left(\frac{1.49}{0.013}\right)(0.833\ \text{ft})^{\frac{2}{3}}\sqrt{0.01}$$

$$= 10.12\ \text{ft/sec}$$

$$d_n = \frac{\left(45\ \frac{\text{ft}^3}{\text{sec}}\right)}{\left(10.12\ \frac{\text{ft}}{\text{sec}}\right)(2.5\ \text{ft})}$$

$$= 1.78\ \text{ft}$$

step 11: Calculate the critical depth. For rectangular channels, Eq. 19.74 can be used.

$$d_c = \left(\frac{Q^2}{gw^2}\right)^{\frac{1}{3}}$$

$$= \left(\frac{\left(45\ \frac{\text{ft}^3}{\text{sec}}\right)^2}{\left(32.2\ \frac{\text{ft}}{\text{sec}^2}\right)(2.5\ \text{ft})^2}\right)^{\frac{1}{3}}$$

$$= 2.16\ \text{ft}$$

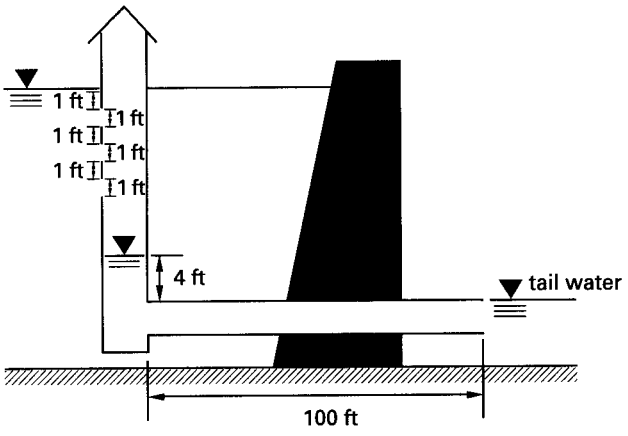
Since the normal depth is less than the critical depth, the flow is supercritical. The entrance control assumption was correct for the culvert. The culvert has sufficient capacity to carry 45 ft^3/sec.

PRACTICE PROBLEMS

Rectangular Channels

1. A wooden flume ($n = 0.012$) with a rectangular cross section is 2 ft wide. The flume carries 3 ft^3/sec of water down a 1% slope. What is the depth of flow?

(A) 0.3 ft
(B) 0.4 ft
(C) 0.5 ft
(D) 0.6 ft



The answer is (A).

2. A rectangular open channel is to be constructed with smooth concrete on a slope of 0.08. The design flow rate is 17 m^3/s. The channel design must be optimum. What are the channel dimensions?

(A) 0.6 m deep; 2.1 m wide
(B) 0.8 m deep; 1.6 m wide
(C) 1.0 m deep; 1.3 m wide
(D) 1.2 m deep; 1.1 m wide

The answer is (B).

3. (*Time limit: one hour*) A dam's outfall structure has three rectangular inlets sized 1 ft high by 2 ft wide as shown. The orifice coefficient for each inlet is 0.7. The vertical riser joins with a 100 ft long square box culvert ($n = 0.013$) placed on a 0.05 slope. The box culvert drains into a tailwater basin whose water level remains constant at the top of the culvert opening. During steady-state operation, the water level in the vertical barrel of the structure is 4 ft above the top of the box culvert. The orifice coefficient of the box culvert entrance is 2/3. What are the dimensions of the box culvert?

(A) 1.5 ft by 1.5 ft
(B) 2.0 ft by 2.0 ft
(C) 2.5 ft by 2.5 ft
(D) 4.0 ft by 4.0 ft

The answer is (C).

Circular Channels

4. A 24 in diameter pipe ($n = 0.013$) was installed 30 years ago on a 0.001 slope. Recent tests indicate that the full-flow capacity of the pipe is 6.0 ft^3/sec.

(a) What was the original full-flow capacity?
(A) 4.1 ft^3/sec
(B) 6.3 ft^3/sec
(C) 6.7 ft^3/sec
(D) 7.2 ft^3/sec

The answer is (D).

(b) What was the original full-flow velocity?
(A) 1.8 ft/sec
(B) 2.3 ft/sec
(C) 2.7 ft/sec
(D) 3.7 ft/sec

The answer is (B).

(c) What is the current full-flow velocity?
(A) 1.9 ft/sec
(B) 2.4 ft/sec
(C) 3.1 ft/sec
(D) 5.8 ft/sec

The answer is (A).

(d) What is the current Manning coefficient?
(A) 0.011
(B) 0.013
(C) 0.016
(D) 0.024

The answer is (C).

5. A circular sewer is to be installed on a 1% grade. Its Manning coefficient is $n = 0.013$. The maximum full-flow capacity is to be 3.5 ft^3/sec.

(a) What size pipe would you recommend?
(A) 8 in
(B) 12 in
(C) 16 in
(D) 18 in

The answer is (B).

(b) Assuming that the diameter chosen is 12 in, what is the full-flow capacity?
(A) 2.7 ft^3/sec
(B) 3.3 ft^3/sec
(C) 3.6 ft^3/sec
(D) 4.5 ft^3/sec

The answer is (C).

(c) What is the full-flow velocity?
(A) 2.9 ft/sec
(B) 3.3 ft/sec
(C) 4.1 ft/sec
(D) 4.6 ft/sec

The answer is (D).

(d) What is the depth of flow when the flow is 0.7 ft^3/sec?
(A) 4 in
(B) 7 in
(C) 9 in
(D) 12 in

The answer is (A).

(e) What minimum velocity will prevent solids from settling out in the sewer?
(A) 1 to 1.5 ft/sec
(B) 1.5 to 2.0 ft/sec
(C) 2.0 to 2.5 ft/sec
(D) 2.5 to 3.0 ft/sec

The answer is (C).

6. A 4 ft diameter concrete storm drain on a 0.02 slope carries water at a depth of 1.5 ft. Manning's roughness coefficient for a full storm drain is $n_{full} = 0.013$, but n varies with depth.

(a) What is the velocity of the water in the storm drain?
(A) 3 ft/sec
(B) 6 ft/sec
(C) 8 ft/sec
(D) 11 ft/sec

The answer is (D).

(b) What is the maximum velocity that can be achieved in the storm drain?

(A) 8 ft/sec
(B) 13 ft/sec
(C) 17 ft/sec
(D) 21 ft/sec

The answer is (C).

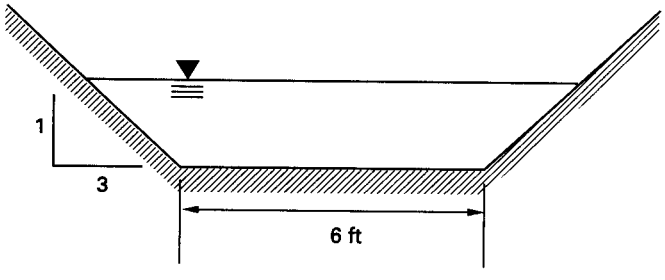
(c) What is the maximum capacity of the storm drain?

(A) 130 ft^3/sec
(B) 160 ft^3/sec
(C) 190 ft^3/sec
(D) 210 ft^3/sec

The answer is (D).

7. A circular storm sewer ($n = 0.012$) is being designed to carry a peak flow of 5 ft^3/sec. To allow for excess capacity, the depth at peak flow is to be 75% of the sewer diameter. The sewer is to be installed in a bed with a slope of 2%. What is the required sewer diameter?

(A) 12 in
(B) 16 in
(C) 20 in
(D) 24 in



The answer is (A).

Trapezoidal Channels

8. The trapezoidal channel shown has a Manning coefficient of $n = 0.013$ and is laid at a slope of 0.002. The depth of flow is 2.0 ft. What is the flow rate?

(A) 120 ft^3/sec
(B) 150 ft^3/sec
(C) 180 ft^3/sec
(D) 210 ft^3/sec

The answer is (B).

9. A trapezoidal open channel is to be constructed with smooth concrete on a slope of 0.08. The design flow rate is 17 m^3/s. The channel design must be optimum. What are the channel dimensions?

(A) depth 0.8 m; base 1.0 m
(B) depth 1.0 m; base 1.2 m
(C) depth 1.2 m; base 1.4 m
(D) depth 1.4 m; base 1.8 m

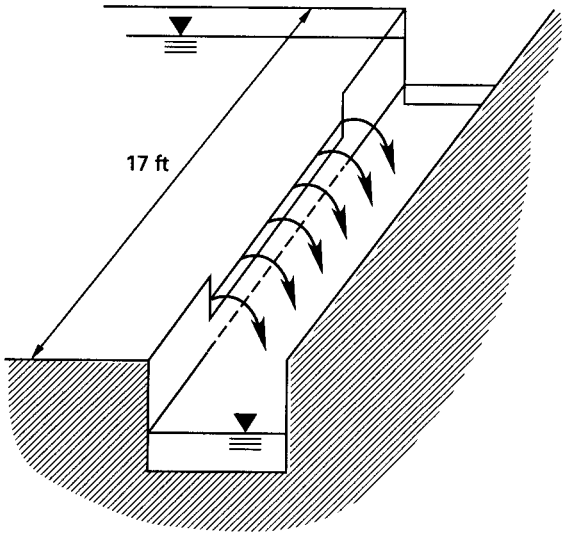
The answer is (A).

Weirs

10. A sharp-crested rectangular weir with two end contractions is 5 ft wide. The weir height is 6 ft. The head over the weir is 0.43 ft. What is the flow rate?

(A) 3.9 ft^3/sec
(B) 4.3 ft^3/sec
(C) 4.6 ft^3/sec
(D) 6.4 ft^3/sec

The answer is (C).



11. A weir is constructed with a trapezoidal opening. The base of the opening is 18 in wide, and the sides have a slope of 4:1 (vertical:horizontal). The depth of flow over the weir is 9 in. What is the rate of discharge?

(A) 1.8 ft^3/sec
(B) 3.3 ft^3/sec
(C) 5.1 ft^3/sec
(D) 8.9 ft^3/sec

The answer is (B).

12. (*Time limit: one hour*) A 17 ft by 20 ft rectangular tank is fed from the bottom and drains through a double-constricted rectangular weir into a trough. The weir opening is to be designed using the following parameters.

discharge rate:	2 MGD minimum
	4 MGD average
	8 MGD maximum
minimum tank freeboard:	4 in
minimum head over weir:	10 in
maximum weir elevation:	590 ft
tank bottom elevation:	580 ft

(a) What is the required weir opening length?
(A) 1.2 ft
(B) 1.4 ft
(C) 2.1 ft
(D) 2.7 ft

The answer is (B).

(b) What is the surface elevation in the tank at maximum flow?
(A) 581.9 ft
(B) 589.8 ft
(C) 592.6 ft
(D) 593.1 ft

The answer is (C).

(c) What is the surface elevation in the tank at minimum flow?
(A) 590.8 ft
(B) 591.2 ft
(C) 591.7 ft
(D) 592.0 ft

The answer is (A).

Hydraulic Jumps and Drops

13. Water flowing in a rectangular channel 5 ft wide experiences a hydraulic jump. The depth of flow upstream from the jump is 1 ft. The depth of flow downstream of the jump is 2.4 ft. What quantity is flowing?
(A) 39 ft^3/sec
(B) 45 ft^3/sec
(C) 52 ft^3/sec
(D) 57 ft^3/sec

The answer is (D).

14. A hydraulic jump forms at the toe of a spillway. The water surface levels are 0.2 ft and 6 ft above the apron before and after the jump, respectively. The velocity before the jump is 54.7 ft/sec. What is the energy loss in the jump?
(A) 41 ft-lbf/lbm
(B) 58 ft-lbf/lbm
(C) 65 ft-lbf/lbm
(D) 92 ft-lbf/lbm

The answer is (A).

15. Water flowing in a rectangular channel 6 ft wide experiences a hydraulic jump. The depth of flow upstream from the jump is 1.2 ft. The depth of flow downstream of the jump is 3.8 ft.

(a) What quantity is flowing?
(A) 75 ft^3/sec
(B) 120 ft^3/sec
(C) 180 ft^3/sec
(D) 210 ft^3/sec

The answer is (B).

(b) What is the energy loss in the jump?
(A) 1 ft-lbf/lbm
(B) 3 ft-lbf/lbm
(C) 5 ft-lbf/lbm
(D) 12 ft-lbf/lbm

The answer is (A).

Spillways

16. A spillway operates with 2 ft of head. The toe of the spillway is 40 ft below the crest of the spillway. The spillway discharge coefficient is 3.5.

(a) What is the discharge per foot of crest?
(A) 9.9 ft^3/sec
(B) 11 ft^3/sec
(C) 15 ft^3/sec
(D) 27 ft^3/sec

The answer is (A).

(b) What is the depth of flow at the toe?
(A) 0.19 ft
(B) 0.35 ft
(C) 0.78 ft
(D) 1.4 ft

The answer is (A).

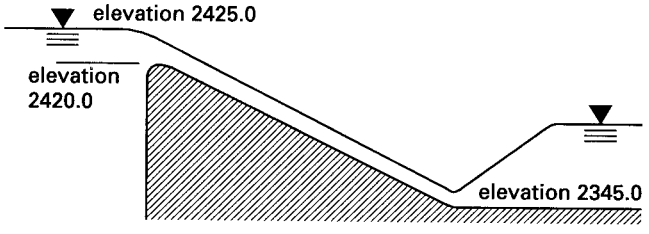
17. 10,000 ft^3/sec of water flow over a 100 ft wide spillway and continue down a constant-width discharge chute on a 5% grade. The discharge chute has a Manning coefficient of $n = 0.012$.

(a) What is the normal depth of the water flowing down the chute?
(A) 1.9 ft
(B) 2.2 ft
(C) 2.7 ft
(D) 3.5 ft

The answer is (B).

(b) What is the critical depth of the water flowing down the chute?
(A) 3.8 ft
(B) 5.1 ft
(C) 6.8 ft
(D) 7.7 ft

The answer is (C).



(c) What type of flow occurs on the chute?
(A) tranquil
(B) subcritical
(C) rapid
(D) nonsteady

The answer is (C).

(d) If a hydraulic jump forms at the bottom of the 5% slope where it joins with a horizontal apron, what is the depth after the jump?
(A) 9.8 ft
(B) 12 ft
(C) 16 ft
(D) 21 ft

The answer is (C).

18. A spillway has a crest length of 60 ft. The stilling basin below the crest has a width of 60 ft and a level bottom. The spillway discharge coefficient is 3.7. The head loss in the chute is 20% of the difference in level between the reservoir surface and the stilling basin bottom.

(a) What is the flow rate over the spillway?
(A) 1800 ft^3/sec
(B) 2100 ft^3/sec
(C) 2500 ft^3/sec
(D) 2900 ft^3/sec

The answer is (C).

(b) What is the depth of flow at the toe of the spillway?
(A) 0.65 ft
(B) 1.2 ft
(C) 1.6 ft
(D) 2.0 ft

The answer is (A).

(c) What tailwater depth is required to cause a hydraulic jump to form at the toe?
(A) 2.9 ft
(B) 3.2 ft
(C) 3.5 ft
(D) 3.8 ft

The answer is (D).

(d) What energy is lost in the hydraulic jump?
(A) 30 ft-lbf/lbm
(B) 50 ft-lbf/lbm
(C) 75 ft-lbf/lbm
(D) 100 ft-lbf/lbm

The answer is (B).

Parshall Flumes

19. A Parshall flume has a throat width of 6 ft. The upstream head measured from the throat floor is 18 in.

(a) What is the flow rate?
(A) 41 ft^3/sec
(B) 46 ft^3/sec
(C) 54 ft^3/sec
(D) 63 ft^3/sec

The answer is (B).

(b) Which of the following is not normally considered to be a feature of Parshall flumes?
(A) They are self-cleansing.
(B) They can be operated by unskilled personnel.
(C) Head loss is small.
(D) They can be placed in temporary installations.

The answer is (D).

Backwater Curves

20. A rectangular channel 8 ft wide carries a flow of 150 ft^3/sec. The channel slope is 0.0015, and the Manning coefficient is $n = 0.015$. A weir installed across the channel raises the depth at the weir to 6 ft.

(a) What is the normal depth of flow?
(A) 2.9 ft
(B) 3.3 ft
(C) 3.6 ft
(D) 4.5 ft

The answer is (B).

(b) What is the distance between the weir and the point where the depth is 5 ft?
(A) 610 ft
(B) 840 ft
(C) 1100 ft
(D) 1700 ft

The answer is (B).

(c) What is the distance between the points where the depth is 4 ft and 5 ft?
(A) 700 ft
(B) 800 ft
(C) 950 ft
(D) 1100 ft

The answer is (D).

Culverts

21. A 42 in diameter concrete culvert is 250 ft long and laid at a slope of 0.006. The culvert entrance is flush and square-edged. The tailwater level at the outlet is just above the crown of the barrel, and the headwater is 5.0 ft above the crown of the culvert's inlet. What is the capacity?

(A) 60 ft^3/sec
(B) 80 ft^3/sec
(C) 100 ft^3/sec
(D) 120 ft^3/sec

The answer is (D).

22. (*Time limit: one hour*) Flow in a 6 ft diameter, newly formed concrete culvert is 150 ft^3/sec at a point where the depth of flow is 3 ft.

(a) What is the hydraulic radius?

(A) 1.1 ft
(B) 1.5 ft
(C) 2.3 ft
(D) 3.0 ft

The answer is (B).

(b) What is the slope of the pipe?

(A) 0.0043
(B) 0.0080
(C) 0.010
(D) 0.030

The answer is (A).

(c) What type of flow occurs?

(A) subcritical
(B) critical
(C) supercritical
(D) choked

The answer is (C).

(d) What is the hydraulic radius if the pipe flows full?

(A) 1.5 ft
(B) 3.0 ft
(C) 4.0 ft
(D) 6.0 ft

The answer is (A).

(e) What is the flow quantity if the culvert flows full?

(A) 100 ft^3/sec
(B) 120 ft^3/sec
(C) 200 ft^3/sec
(D) 300 ft^3/sec

The answer is (D).

(f) What is the critical depth?

(A) 1.1 ft
(B) 1.5 ft
(C) 3.3 ft
(D) 4.3 ft

The answer is (C).

(g) What is the critical slope?

(A) 0.002
(B) 0.003
(C) 0.004
(D) 0.05

The answer is (B).

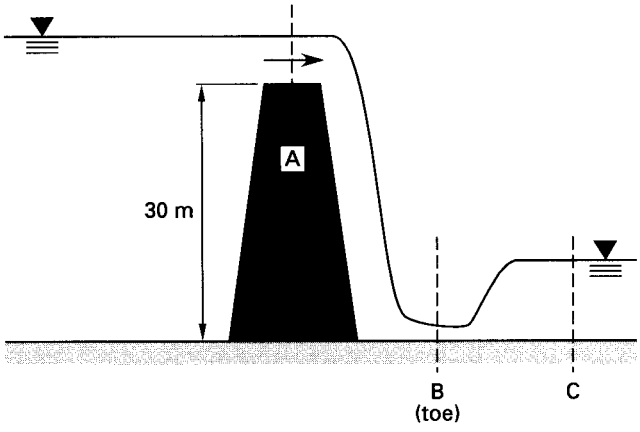
(h) If the exit depth is less than critical, which culvert flow types are most probable?

(A) 1, 5
(B) 1, 3, 5
(C) 1, 2, 3
(D) 5 only

The answer is (A).

(i) What is the Froude number for a depth of flow of 3 ft?

(A) 0.86
(B) 0.99
(C) 1.22
(D) 2.84



The answer is (C).

(j) After the water exits the culvert, it flows at a velocity of 15 ft/sec and a depth of 2 ft. Assuming a hydraulic jump is possible, what will be the depth after the jump?

(A) 2.5 ft
(B) 3.0 ft
(C) 3.3 ft
(D) 4.4 ft

The answer is (D).

23. (*Time limit: one hour*) A dam spills 2000 m^3/s of water over its crest as shown. The crest height is 30 m. The width of the dam is 150 m. The depth at point B is 0.6 m. The stilling basin, constructed of rough concrete, is rectangular in shape, 150 m in width, and has a slope of 0.002.

(a) What is the head over the crest?
(A) 0.8 m
(B) 1.2 m
(C) 2.2 m
(D) 3.4 m

The answer is (C).

(b) What is the total upstream specific energy head?
(A) 32.2 m
(B) 34.1 m
(C) 36.1 m
(D) 38.0 m

The answer is (B).

(c) What is the total specific energy head at point B?
(A) 25.8 m
(B) 32.2 m
(C) 34.1 m
(D) 43.3 m

The answer is (A).

(d) What is the friction head loss between points A and B?
(A) 2.2 m
(B) 4.2 m
(C) 8.3 m
(D) 9.8 m

The answer is (C).

(e) What is the normal downstream depth?
(A) 2.0 m
(B) 2.6 m
(C) 5.6 m
(D) 10.0 m

The answer is (B).

(f) What is the critical depth?
(A) 2.0 m
(B) 2.6 m
(C) 7.0 m
(D) 8.3 m

The answer is (B).

(g) At what point will a hydraulic jump occur?
(A) on the spillway slope
(B) at point B
(C) downstream of point B
(D) nowhere (a hydraulic jump will not occur)

The answer is (D).

(h) The stilling basin feeds into a natural channel composed of graded material from silt to cobble size. What is the maximum velocity in this channel to prevent erosion?
(A) 1.2 m/s
(B) 6.7 m/s
(C) 15.0 m/s
(D) 26.0 m/s

The answer is (A).

(i) If the natural channel has the same geometry as the stilling basin (i.e., rectangular with a width of 150 m) and the depth remains the same, what slope is required to maintain the maximum velocity and prevent erosion?
(A) 0.0001
(B) 0.0003
(C) 0.002
(D) 0.02

The answer is (B).

(j) Assuming that the slope in the natural channel remains at 0.002, what is the friction loss over a 1000 m reach?
(A) 0.1 m
(B) 0.6 m
(C) 1.5 m
(D) 2.0 m

The answer is (D).

1. HYDROLOGIC CYCLE

The *hydrologic cycle* is the full "life cycle" of water. The cycle begins with *precipitation*, which encompasses all of the hydrometeoric forms, including rain, snow, sleet, and hail from a storm. Precipitation can (a) fall on vegetation and structures and evaporate back into the atmosphere, (b) be absorbed into the ground and either make its way to the water table or be absorbed by plants after which it evapotranspires back into the atmosphere, or (c) travel as surface water to a depression, watershed, or creek from which it either evaporates back into the atmosphere, infiltrates into the ground water system, or flows off in streams and rivers to an ocean or lakes. The cycle is completed when lake and ocean water evaporates into the atmosphere.

The *water balance equation* is the application of conservation to the hydrologic cycle.

$$\begin{aligned}\text{total precipitation} &= \text{net change in surface water removed}\\ &\quad + \text{net change in ground water removed}\\ &\quad + \text{evapotranspiration}\\ &\quad + \text{interception evaporization}\\ &\quad + \text{net increase in surface water storage}\\ &\quad + \text{net increase in ground water storage}\end{aligned} \qquad 20.1$$

The total amount of water that is intercepted (and which subsequently evaporates) and absorbed into ground water before runoff begins is known as the *initial abstraction.* Even after runoff begins, the soil continues to absorb some infiltrated water. Initial abstraction and infiltration do not contribute to surface runoff. Equation 20.1 can be restated as Eq. 20.2.

$$\begin{aligned}\text{total precipitation} &= \text{initial abstraction}\\ &\quad + \text{infiltration}\\ &\quad + \text{surface runoff}\end{aligned} \qquad 20.2$$

2. STORM CHARACTERISTICS

Storm rainfall characteristics include the duration, total volume, intensity, and areal distribution of a storm. Storms are also characterized by their recurrence intervals. (See Sec. 6.)

The duration of storms is measured in hours and days. The volume of rainfall is simply the total quantity of precipitation dropping on the watershed. Average rainfall intensity is the volume divided by the duration of the storm. Average rainfall can be considered to be generated by an equivalent theoretical storm that drops the same volume of water uniformly and constantly over the entire watershed area.

A storm *hyetograph* is the instantaneous rainfall intensity measured as a function of time. Hyetographs are usually bar graphs showing constant rainfall intensities over short periods of time. Hyetograph data can be reformulated as a *cumulative rainfall curve*, also known as a rainfall *mass curve.*

3. PRECIPITATION DATA

Precipitation data on rainfall can be collected in a number of ways, but use of an open precipitation rain gauge is quite common. This type of gauge measures only the volume of rain collected between readings, usually 24 hr.

The *average precipitation* over a specific area can be found from station data in several ways.

Method 1: If the stations are uniformly distributed over a flat site, their precipitations can be averaged. This also requires that the individual precipitation records not vary too much from the mean.

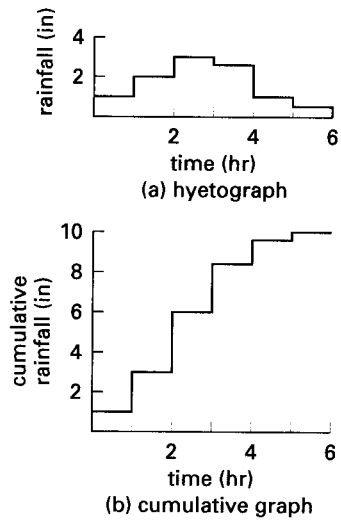

Figure 20.1 *Storm Hyetograph and Cumulative Rainfall Curves*

Method 2: The *Thiessen method* calculates the average by weighting station measurements by the area of the assumed watershed for each station. These assumed watershed areas are found by drawing dotted lines between all stations and bisecting these dotted lines with solid lines (which are extended outward until they connect with other solid lines). The solid lines will form a polygon whose area is the assumed watershed area.

Method 3: The *isohyetal method* requires plotting lines of constant precipitation (*isohyets*) and weighting the isohyet values by the areas enclosed by the lines. This method is the most accurate of the three methods, as long as there are enough observations to permit drawing of isohyets. Station data are used to draw isohyets, but they are not used in the calculation of average rainfall.

4. ESTIMATING UNKNOWN PRECIPITATION

If a precipitation measurement at a location is unknown, it may still be possible to estimate the value by one of the following procedures.

Method 1: Choose three stations close to and evenly spaced around the location with missing data. If the normal annual precipitations at the three sites do not vary more than 10% from the missing station's normal annual precipitation, the rainfall can be estimated as the arithmetic mean of the three neighboring stations' precipitations for the period in question.

Method 2: If the precipitation difference between locations is more than 10%, the *normal-ratio method* can be used. In Eq. 20.3, P_x is the precipitation at the missing station; N_x is the long-term normal precipitation at the missing station; P_A, P_B, and P_C are the precipitations at known stations; and N_A, N_B, and N_C are the long-term normal precipitations at the known stations.

$$P_x = \tfrac{1}{3}\left[\left(\frac{N_x}{N_A}\right)P_A + \left(\frac{N_x}{N_B}\right)P_B + \left(\frac{N_x}{N_C}\right)P_C\right] \qquad 20.3$$

Method 3: Use data from stations in the four nearest quadrants (north, south, east, and west of the unknown station) and weight the data with the square of the distance between the stations. In Eq. 20.4, P_x, P_A, P_B, P_C, and P_D are defined as in Method 2, and d_{A-x}, d_{B-x}, d_{C-x}, and d_{D-x} are the distances between stations A and x, B and x, and so on, respectively.

$$P_x = \frac{d_{A-x}^2 P_A + d_{B-x}^2 P_B + d_{C-x}^2 P_C + d_{D-x}^2 P_D}{d_{A-x}^2 + d_{B-x}^2 + d_{C-x}^2 + d_{D-x}^2} \qquad 20.4$$

5. TIME OF CONCENTRATION

Time of concentration, t_c, is defined as the time of travel from the hydraulically most remote (timewise) point in the watershed to the watershed outlet or other design point. For points (e.g., manholes) along storm drains being fed from a watershed, time of concentration is taken as the largest combination of overland flow time (sheet flow), swale or ditch flow (shallow concentrated flow), and storm drain, culvert, or channel time.

$$t_c = t_{\text{sheet}} + t_{\text{shallow}} + t_{\text{channel}} \qquad 20.5$$

The Soil Conservation Service (SCS) specifies using the *Manning kinematic equation* (Overton and Meadows 1976 formulation) for calculating *sheet flow* travel time over distances less than 300 ft (100 m). In Eq. 20.6, n is the Manning roughness coefficient for sheet flow (Table 20.1), P_2 is the 2 yr, 24 hr rainfall in inches, and S is the slope of the hydraulic grade line in ft/ft.

$$t_{\text{sheet flow}} = \frac{0.007(nL_o)^{0.8}}{\sqrt{P_2}(S_{\text{decimal}})^{0.4}} \qquad 20.6$$

Table 20.1 *Manning Roughness Coefficient for Sheet Flow*

surface	n
smooth surfaces (concrete, asphalt, gravel, or bare soil)	0.011
fallow (no residue cover)	0.05
cultivated soils	
residue cover $\leq$ 20%	0.06
residue cover $>$ 20%	0.17
grasses	
short prairie grass	0.15
dense grass[a]	0.24
Bermuda grass	0.41
range, natural	0.13
woods[b]	
light underbrush	0.40
dense underbrush	0.80

[a]Includes species such as weeping lovegrass, bluegrass, buffalo grass, blue gramma grass, and native grass mixtures.
[b]When selecting a value of n, consider the cover to a height of about 0.1 ft (3 cm). This is the only part of the plant that will obstruct sheet flow.

Reprinted from *Urban Hydrology for Small Watersheds*, Technical Release TR 55, United States Department of Agriculture, Soil Conservation Service, Table 3-1, after Engman (1986).

After about 300 ft (100 m), the flow usually becomes shallow concentrated flow (swale, ditch flow). Travel time is calculated as L/v. Velocity can be found from the Manning equation if the flow geometry is well defined, but must be determined from other correlations otherwise, such as those specified by the SCS in Eqs. 20.7 and 20.8.

$$v_{\text{shallow}} = 16.1345\sqrt{S_{\text{decimal}}} \quad \text{[unpaved]} \qquad 20.7$$

$$v_{\text{shallow}} = 20.3282\sqrt{S_{\text{decimal}}} \quad \text{[paved]} \qquad 20.8$$

Storm drain time is found by dividing the storm drain length by the actual or an assumed channel velocity. Storm drain velocity is found from either the Manning or the Hazen-Williams equation. Since size and velocity are related, an iterative trial-and-error solution is generally required.[1]

There are a variety of methods available for estimating time of concentration. Early methods include Kirpich (1940), California Culverts Practice (1942), Hathaway (1945), and Izzard (1946). More recent methods include those from the Federal Aviation Administration, or FAA (1970), the kinematic wave formulas of Morgali (1965) and Aron (1973), the SCS lag equation (1975), and SCS average velocity charts (1975). Estimates of time of concentration from these methods can vary by as much as 100%. These differences carry over into estimates of peak flow, hence the need to carefully determine the validity of any method used.

The distance L_o in the various equations that follow is the longest distance to the collection point, as shown in Fig. 20.2.

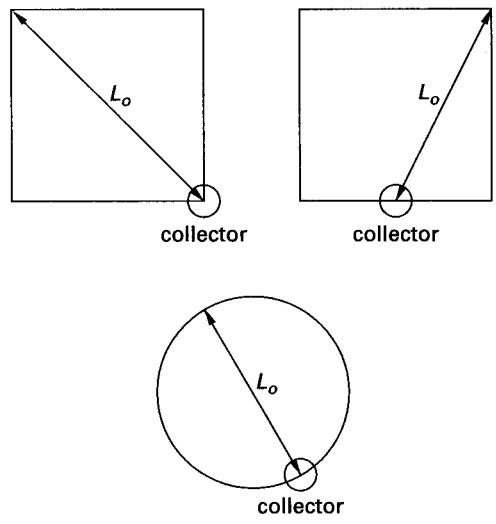

Figure 20.2 *Overland Flow Distances*

[1]If the pipe or channel size is known, the velocity can be found from $Q = Av$. If the pipe size is not known, the area will have to be estimated. In that case, one might as well estimate velocity instead. 5 ft/sec is a reasonable flow velocity for open channel flow. The minimum velocity for a *self-cleansing pipe* is 2 ft/sec.

For irregularly shaped drainage areas, it may be necessary to evaluate several alternative overland flow distances. For example, Fig. 20.3 shows a drainage area with a long tongue. Although the tongue area contributes little to the drainage area, it does lengthen the overland flow time. Depending on the intensity-duration-frequency curve, the longer overland flow time (resulting in a lower rainfall intensity) may offset the increase in area due to the tongue. Therefore, two runoffs need to be compared, one ignoring and the other including the tongue.

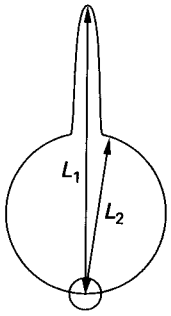

Figure 20.3 *Irregular Drainage Area*

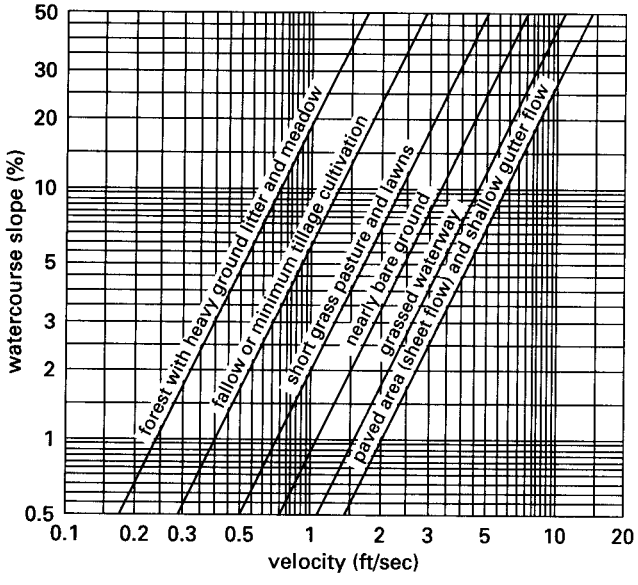
The *FAA formula*, Eq. 20.9, was developed from airfield drainage data collected by the Army Corp of Engineers. However, it has been widely used for urbanized areas. C is the rational method runoff coefficient. The slope in Eq. 20.9 is in percent. L_o is in ft.

$$t_c = \frac{(1.8)(1.1 - C)\sqrt{L_{o,\text{ft}}}}{S_{\text{percent}}^{\frac{1}{3}}} \qquad 20.9$$

The *kinematic wave formula* is particularly accurate for paved areas such as parking lots and streets. It requires iteration, since both intensity and time of concentration are unknown. In Eq. 20.10, L_o is in ft, n is the Manning roughness coefficient, I is the intensity in in/hr, and S_{decimal} is the slope in ft/ft. Recommended values of n for this application are somewhat different than for open channel flow and are: smooth impervious surfaces, 0.035; smooth bare-packed soil, free of stones, 0.05; poor grass, moderately bare surface, 0.10; pasture or average grass cover, 0.20; dense grass or forest, 0.40.



$$t_c = \frac{0.94 L_{o,\text{ft}}^{0.6} n^{0.6}}{I^{0.4} S_{\text{decimal}}^{0.3}} \qquad 20.10$$

The SCS *lag equation* was developed from observations of agricultural watersheds where overland flow paths are poorly defined and channel flow is absent. However, it has been adapted to small urban watersheds under 2000 ac. The equation performs reasonably well for areas that are completely paved, as well. Correction factors are used to account for channel improvement and impervious areas. L_o is in ft, CN is the SCS runoff curve number, and S is the average slope in percent. The factor 1.67 converts the watershed lag time to the time of concentration. Since the formula overestimates time for mixed areas, different adjustment factors have been proposed. The SCS lag equation performs poorly when channel flow is a significant part of the time of concentration.

$$t_c = \frac{1.67 L_{o,\text{ft}}^{0.8} \left(\frac{1000}{\text{CN}} - 9\right)^{0.7}}{1900\sqrt{S_{\text{percent}}}} \qquad 20.11$$

If the velocity of runoff water is known, the time of concentration can be easily determined. Charts of average velocity as functions of watercourse slope and surface cover have been published by the SCS. The charts are best suited for flow paths of at least several hundred feet (at least 70 m). The time of concentration is easily determined from these charts as

$$t_c = \frac{\sum L_{o,\text{ft}}}{\text{v}\left(60\ \frac{\text{sec}}{\text{min}}\right)} \qquad 20.12$$

Reprinted from SCS TR-55-1975. TR-55-1986 contains a similar graph for shallow-concentrated flow over paved and unpaved surfaces, but it does not contain this particular graph.

Figure 20.4 *SCS Average Velocity Chart for Overland Flow Travel Time*

6. RAINFALL INTENSITY

Effective design of a surface feature depends on its geographical location and required degree of protection. Once the location of the feature is known, the *design storm* (or *design flood*) must be determined based on some probability of recurrence.

Rainfall intensity is the amount of precipitation per hour. The instantaneous intensity changes throughout the storm. However, it may be averaged over short time

intervals or over the entire storm duration. Average intensity will be low for most storms, but it can be high for some. These high-intensity storms can be expected infrequently, say, every 20, 50, or 100 years. The average number of years between storms of a given intensity is known as the *frequency of occurrence* or *recurrence interval.*

In general, the design storm may be specified by its recurrence interval (e.g., "100-year storm"), its annual probability of occurrence (e.g., "1% storm"), or a nickname (e.g., "century storm"). A 1% storm is a storm that would be exceeded in severity only once every hundred years on the average.

The average intensity of a storm over a time period t can be calculated from Eq. 20.13 (and similar correlations). (When using the rational method described in Sec. 15, t is the time of concentration.) In the United States, it is understood that the units of intensity calculated using Eq. 20.13 will be in in/hr.

$$I = \frac{K'F^a}{(t+b)^c} \qquad 20.13$$

K', F, a, b, and c are constants that depend on the conditions, recurrence interval, and location of a storm. For many reasons, these constants may be unavailable. The *Steel formula* is a simplification of Eq. 20.13.

$$I = \frac{K}{t_c + b} \qquad 20.14$$

Values of the constants K and b in Eq. 20.14 are not difficult to obtain once the intensity-duration-frequency curve is established. Although a logarithmic transformation could be used to convert the data to straight-line form, an easier method exists. This method starts by taking the reciprocal of Eq. 20.14 and converting the equation to a straight line.

$$\begin{aligned} \frac{1}{I} &= \frac{t_c + b}{K} \\ &= \frac{t_c}{K} + \frac{b}{K} \\ &= C_1 t_c + C_v \end{aligned} \qquad 20.15$$

Once C_1 and C_2 have been found, K and b can be calculated.

$$K = \frac{1}{C_1} \qquad 20.16$$

$$b = \frac{C_2}{C_1} \qquad 20.17$$

Published values of K and b can be obtained from compilations, but these values are suitable only for very rough estimates. Table 20.2 is typical of some of this general data.

The total rainfall can be calculated from the duration.

$$P = It \qquad 20.18$$

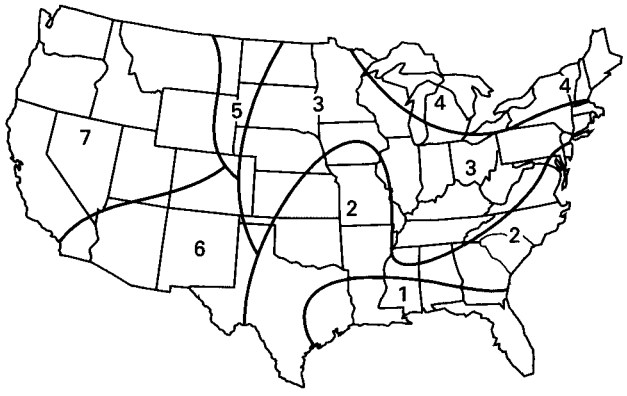


Figure 20.5 *Steel Formula Rainfall Regions*

Table 20.2 *Steel Formula Coefficients (for intensities of in/hr)*

frequency in years	coefficients	region 1	2	3	4	5	6	7
2	K	206	140	106	70	70	68	32
	b	30	21	17	13	16	14	11
4	K	247	190	131	97	81	75	48
	b	29	25	19	16	13	12	12
10	K	300	230	170	111	111	122	60
	b	36	29	23	16	17	23	13
25	K	327	260	230	170	130	155	67
	b	33	32	30	27	17	26	10
50	K	315	350	250	187	187	160	65
	b	28	38	27	24	25	21	8
100	K	367	375	290	220	240	210	77
	b	33	36	31	28	29	26	10

(Multiply in/hr by 2.54 to obtain cm/h.)

Rainfall data can be compiled into *intensity-duration-frequency curves (IDF curves)* similar to those in Fig. 20.6.

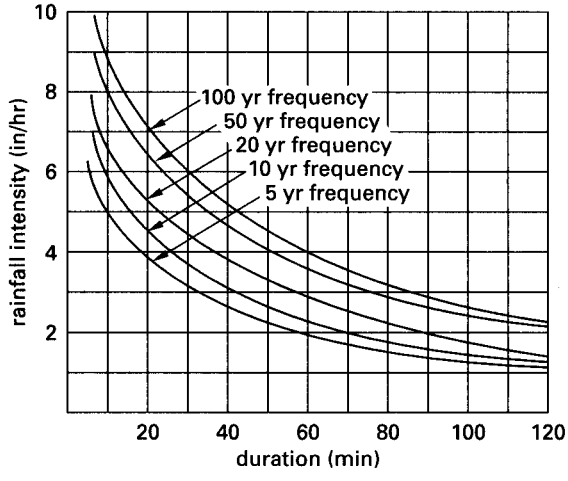

Figure 20.6 *Typical Intensity-Duration-Frequency Curves*

Example 20.1

A storm has an intensity given by

$$I = \frac{100}{t_c + 10}$$

15 min are required for runoff from the farthest corner of a 5 ac watershed to reach a discharge culvert. What is the design intensity?

Solution

The intensity is

$$I = \frac{100}{t_c + 10} = \frac{100\ \frac{\text{in-min}}{\text{hr}}}{15\ \text{min} + 10\ \text{min}}$$
$$= 4\ \text{in/hr}$$

7. FLOODS

A *flood* occurs when more water arrives than can be drained away. When a watercourse (i.e., a creek or river) is too small to contain the flow, the water overflows the banks.

The flooding may be categorized as nuisance, damaging, or devastating. *Nuisance floods* result in inconveniences such as wet feet, tire spray, and soggy lawns. *Damaging floods* soak flooring, carpeting, and first-floor furniture. *Devastating floods* wash buildings, vehicles, and livestock downstream.

Although rain causes flooding, large storms do not always cause floods. The size of a flood depends not only on the amount of rainfall, but also on the conditions within the watershed before and during the storm. Runoff will occur only when the rain falls on a very wet watershed that is unable to absorb additional water, or when a very large amount of rain falls on a dry watershed faster than it can be absorbed.

Specific terms are sometimes used to designate the degree of protection required. For example, the *probable maximum flood* (PMF) is a hypothetical flood that can be expected to occur as a result of the most severe combination of critical meteorologic and hydrologic conditions possible within a region.

Designing for the *probable maximum precipitation* (PMP) or *probable maximum flood* (PMF) is very conservative and usually uneconomical since the recurrence interval for these events exceeds 100 yr and may even approach 1000 yr. Designing for 100 yr floods and rain storms with even lower recurrence intervals is more common.

The *design flood* or *design basis flood* (DBF) depends on the site. It is the flood that is adopted as the basis for design of a particular project. The DBF is usually determined from economic considerations, or it is specified as part of the contract document.

The *standard flood* or *standard project flood* (SPF) is a flood that can be selected from the most severe combinations of meteorological and hydrological conditions reasonably characteristic of the region, excluding extremely rare combinations of events. SPF volumes are commonly 40 to 60% of the PMF volumes.

The probability that a flooding event in any year will equal a design basis flood with a recurrence interval of F is

$$p\{F \text{ event in one year}\} = \frac{1}{F} \qquad 20.19$$

The probability of an F event occurring in n years is

$$p\{F \text{ event in } n \text{ years}\} = 1 - \left(1 - \frac{1}{F}\right)^n \qquad 20.20$$

Planning for a 1% flood has proven to be a good compromise between not doing enough and spending too much. Although the 1% flood is a common choice for the design basis flood, shorter recurrence intervals are often used, particularly in low-value areas such as cropland. For example, a 5 yr value can be used in residential areas, a 10 yr value in business sections, and a 15 yr value for high-value districts where flooding will result in more extensive damage. The ultimate choice of recurrence interval, however, must be made on the basis of economic considerations and trade-offs.

Example 20.2

A wastewater treatment plant has been designed to be in use for 40 yr. What is the probability that a 1% flood will occur within the useful lifetime of the plant?

Solution

Use Eq. 20.20.

$$p\{F \text{ event in } n \text{ years}\} = 1 - \left(1 - \frac{1}{F}\right)^n$$
$$p\{100\text{-yr flood in 40 years}\} = 1 - \left(1 - \frac{1}{100}\right)^{40}$$
$$= 0.33 \quad (33\%)$$

8. TOTAL SURFACE RUNOFF FROM STREAM HYDROGRAPH

After a rain, runoff and groundwater increases stream flow. A plot of the stream discharge versus time is known as a *hydrograph*. Hydrograph periods may be very short (e.g., hours) or very long (e.g., days, weeks, or months). A typical hydrograph is shown in Fig. 20.7. The *time base* is the length of time that the stream flow exceeds the original *base flow*. The flow rate increases on the *rising limb* (*concentration curve*) and decreases on the *falling limb* (*recession curve*).

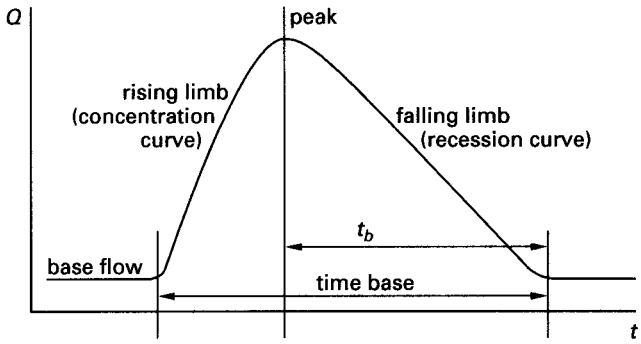

Figure 20.7 *Stream Hydrograph*

9. HYDROGRAPH SEPARATION

The stream discharge consists of both runoff and groundwater (subsurface) flows. Since culverts do not have to be designed to carry groundwater flow, a procedure known as *hydrograph separation* or *hydrograph analysis* is necessary to separate runoff (*surface flow, net flow,* or *overland flow*) and groundwater (*base flow*).[2]

There are many methods of separating base flow from overland flow. Most of the methods are somewhat arbitrary. Three methods that are easily carried out manually are presented here.

Method 1: In the *straight-line method*, a horizontal line is drawn from the start of the rising limb to the falling limb. All of the flow under the horizontal line is considered base flow. This assumption is not theoretically accurate, but the error can be small. This method is illustrated in Fig. 20.8.

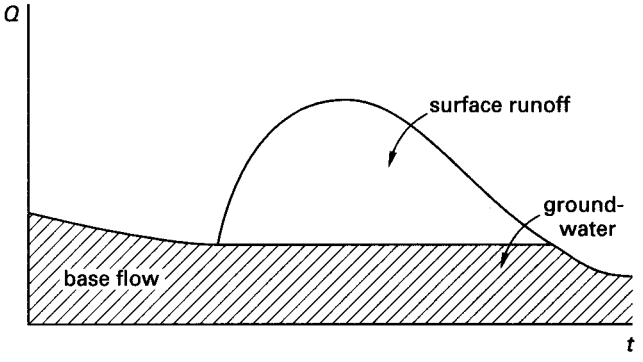

Figure 20.8 *Straight-Line Method*

Method 2: In the *fixed-base method*, the base flow existing before the storm is projected graphically down to a point directly under the peak of the hydrograph. Then, a straight line is used to connect the projection to the falling limb. The duration of the recession limb is determined by inspection, or it can be calculated from correlations with the drainage area.

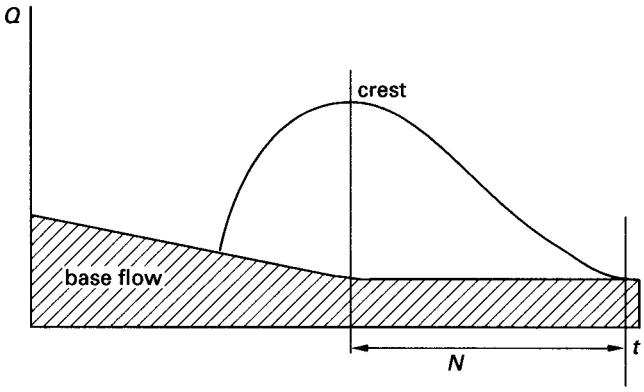

Figure 20.9 *Fixed-Base Method*

Method 3: The *variable-slope method* recognizes that the shape of the base flow curve before the storm will probably match the shape of the base flow curve after the storm. The groundwater curve after the storm is projected back under the hydrograph to a point under the inflection point of the falling limb. The separation line under the rising limb is drawn arbitrarily.

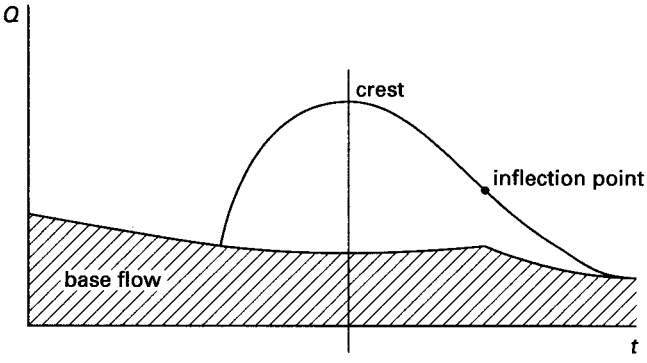

Figure 20.10 *Variable-Slope Method*

Once the base flow is separated out, the hydrograph of surface runoff will have the approximate appearance of Fig. 20.11.

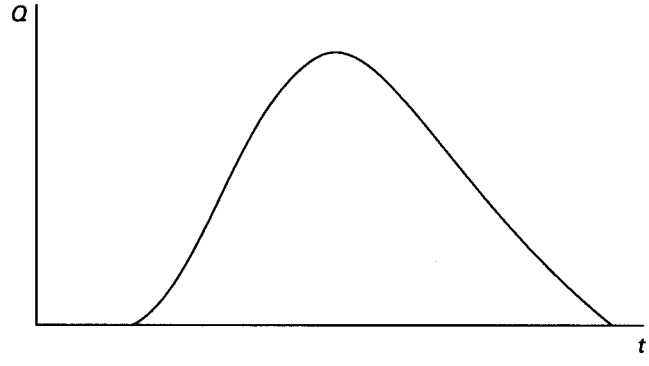

Figure 20.11 *Overland Flow Hydrograph*

[2]The total rain dropped by a storm is the *gross rain*. The rain that actually appears as immediate runoff can be called *surface runoff, overland flow, surface flow,* and *net rain*. The water that is absorbed by the soil and that does not contribute to the surface runoff can be called *base flow, groundwater, infiltration,* and *dry weather flow*.

10. UNIT HYDROGRAPH

Once the overland flow hydrograph for a watershed has been developed, the total rainfall volume, V, from the storm can be found as the area under the curve. Although this can be found by integration, planimetry, or computer methods, it is often sufficiently accurate to approximate the hydrograph with a histogram and to sum the areas of the rectangles.

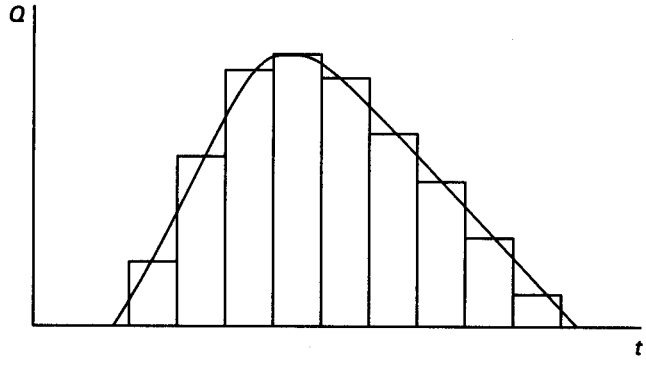

Figure 20.12 *Hydrograph Histogram*

Since the area of the watershed is known, the average depth, P_{ave}, of precipitation can be calculated. (Consistent units must be used in Eq. 20.21.)

$$V = A_d P_{ave} \qquad 20.21$$

A *unit hydrograph* (UH) is developed by dividing every point on the overland flow hydrograph by the average precipitation, P_{ave}. This is a hydrograph of a storm dropping 1 in (1 cm) of rain evenly on the entire watershed. Units of the unit hydrograph are in/in (cm/cm). Figure 20.13 shows how a unit hydrograph compares to its surface runoff hydrograph.

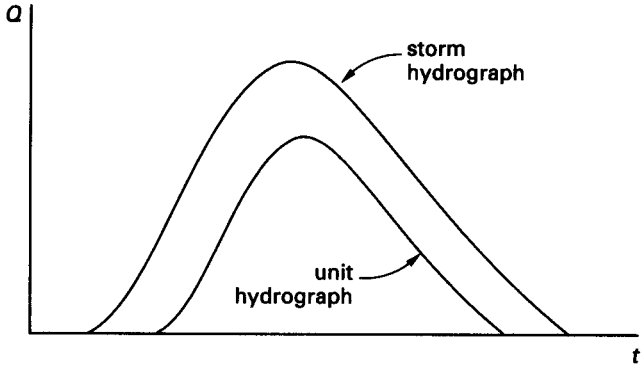

Figure 20.13 *Unit Hydrograph*

Once a unit hydrograph has been developed from historical data of a particular storm volume, it can be used for other storm volumes. Such application is based on several assumptions: (a) All storms in the watershed have the same duration, (b) the time base is constant for all storms, (c) the shape of the rainfall curve is the same for all storms, and (d) only the total amount of rainfall varies from storm to storm.

The hydrograph of a storm producing more or less than 1 in (1 cm) of rain is found by multiplying all ordinates on the unit hydrograph by the total precipitation of the storm.

A unit hydrograph can be used to predict the runoff for storms that have durations somewhat different than the storms used to develop the unit hydrograph. Generally, storm durations differing by up to ±25% are considered to be equivalent.

Example 20.3

After a 2 hr storm, a station downstream from a 45 mi^2 (115 km^2) drainage watershed records a peak discharge of 9400 ft^3/sec (250 m^3/s) and a total runoff of 3300 ac-ft (4×10^6 m^3). (a) What is the unit hydrograph peak discharge? (b) What would be the peak runoff and design flood volume if a 2 hr storm dropped 2.5 in (6 cm) net precipitation?

SI Solution

(a) Use Eq. 20.21 to find the average precipitation for the drainage watershed.

$$P_{ave} = \frac{V}{A_d} = \frac{4 \times 10^6 \text{ m}^3}{(115 \text{ km}^2)\left(1000 \frac{\text{m}}{\text{km}}\right)^2}$$
$$= 0.0348 \text{ m} \quad (3.5 \text{ cm})$$

The ordinates for the unit hydrograph are found by dividing every point on the 3.5 cm hydrograph by 3.5 cm. Therefore the peak discharge for the unit hydrograph is

$$Q_{p,\text{unit}} = \frac{250 \frac{\text{m}^3}{\text{s}}}{3.5 \text{ cm}}$$
$$= 71.4 \text{ m}^3/\text{s·cm}$$

(b) The hydrograph for a storm producing more than 1 cm of rain is found by multiplying the ordinates of the unit hydrograph by the total precipitation. For a 6 cm storm, the peak discharge is

$$Q_p = \left(71.4 \frac{\text{m}^3}{\text{s·cm}}\right)(6 \text{ cm})$$
$$= 429 \text{ m}^3/\text{s}$$

To find the design flood volume, first use Eq. 20.21 to find the unit hydrograph total volume.

$$V = PA_d = \left(1 \frac{\text{cm}}{\text{cm}}\right)\left(\frac{1 \text{ m}}{100 \text{ cm}}\right)(115 \text{ km}^2)\left(1000 \frac{\text{m}}{\text{km}}\right)^2$$
$$= 1.15 \times 10^6 \text{ m}^3/\text{cm}$$

The design flood volume for a 6 cm storm is

$$V = (6 \text{ cm})\left(1.15 \times 10^6 \frac{\text{m}^3}{\text{cm}}\right)$$
$$= 6.9 \times 10^6 \text{ m}^3$$

Customary U.S. Solution

(a) Use Eq. 20.21 to find the average precipitation for the drainage watershed.

$$P_{\text{ave}} = \frac{V}{A_d}$$
$$= \frac{(3300 \text{ ac-ft})\left(43{,}560 \frac{\text{ft}^2}{\text{ac}}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)}{(45 \text{ mi}^2)\left(5280 \frac{\text{ft}}{\text{mi}}\right)^2}$$
$$= 1.375 \text{ in}$$

The ordinates for the unit hydrograph are found by dividing every point on the 1.375 in hydrograph by 1.375 in. Therefore, the peak discharge for the unit hydrograph is

$$Q_{p,\text{unit}} = \frac{9400 \frac{\text{ft}^3}{\text{sec}}}{1.375 \text{ in}}$$
$$= 6836 \text{ ft}^3/\text{sec-in}$$

(b) The hydrograph for a storm producing more than 1 in of rain is found by multiplying the ordinates of the unit hydrograph by the total precipitation. For a 2.5 in storm, the peak discharge is

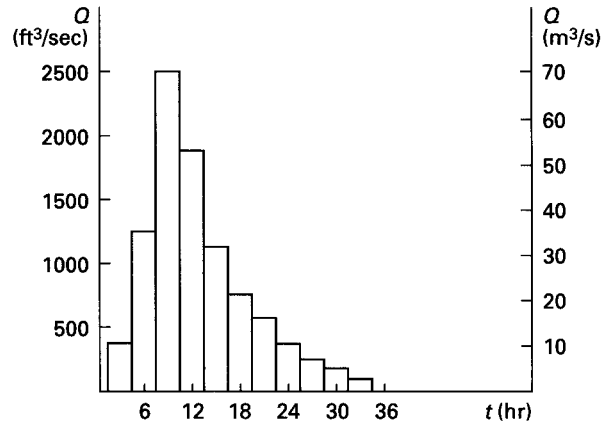
$$Q_p = \left(6836 \frac{\text{ft}^3}{\text{sec-in}}\right)(2.5 \text{ in})$$
$$= 17{,}091 \text{ ft}^3/\text{sec}$$

To find the design flood volume, first use Eq. 20.21 to find the unit hydrograph total volume.

$$V = PA_d = \left(1 \frac{\text{in}}{\text{in}}\right)(45 \text{ mi}^2)\left(53.3 \frac{\text{ac-ft}}{\text{mi}^2\text{-in}}\right)$$
$$= 2399 \text{ ac-ft/in}$$

The design flood volume for the 2.5 in storm is

$$V = (2.5 \text{ in})\left(2399 \frac{\text{ac-ft}}{\text{in}}\right) = 5996 \text{ ac-ft}$$



Example 20.4

A 6 hr storm rains on a 25 mi^2 (65 km^2) drainage watershed. Records from a stream gauging station are shown. (a) Construct the unit hydrograph for the 6 hr storm. (b) Find the runoff rate at $t = 15$ hr from a two-storm system if the first storm drops 2 in (5 cm) starting at $t = 0$ and the second storm drops 5 in (12 cm) starting at $t = 12$ hr.

t (hr)	Q (ft^3/sec)	Q (m^3/s)
0	0	0
3	400	10
6	1300	35
9	2500	70
12	1700	50
15	1200	35
18	800	20
21	600	15
24	400	10
27	300	10
30	200	5
33	100	3
36	0	0
Totals	9500	263

SI Solution

(a) Plot the stream gauging data.

The total runoff is the total area under the curve, found by multiplying the total runoff by the rainfall data interval. This is equivalent to summing the areas of each rectangle of the histogram.

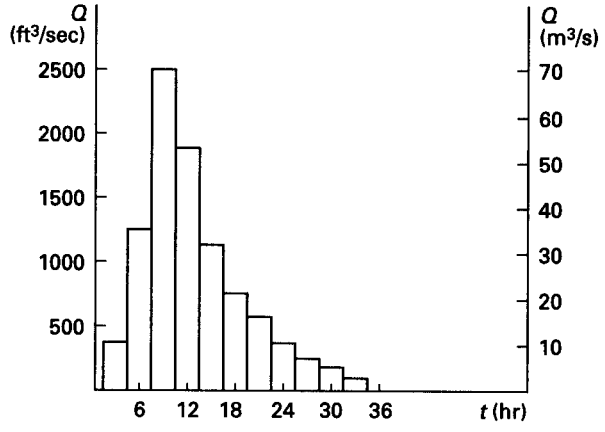
$$V = \left(263 \frac{\text{m}^3}{\text{s}}\right)(3 \text{ h})\left(3600 \frac{\text{s}}{\text{h}}\right) = 2.8404 \times 10^6 \text{ m}^3$$

The watershed drainage area is

$$A_d = (65 \text{ km}^2)\left(1000 \frac{\text{m}}{\text{km}}\right)^2$$
$$= 65 \times 10^6 \text{ m}^2$$

The average precipitation is calculated from Eq. 20.21.

$$P = \frac{V}{A_d}$$
$$= \frac{(2.8404 \times 10^6 \text{ m}^3)\left(100 \frac{\text{cm}}{\text{m}}\right)}{65 \times 10^6 \text{ m}^2}$$
$$= 4.37 \text{ cm}$$



The unit hydrograph has the same shape as the actual hydrograph with all ordinates reduced by a factor of 4.37.

(b) To find the flow at 15 hr, add the contributions from each storm. For the 5 cm storm, the contribution is the 15 hr runoff multiplied by its scaling factors; for the 12 cm storm, the contribution is the 15 hr − 12 hr = 3 hr runoff multiplied by its scaling factors.

$$Q = \frac{(5 \text{ cm})\left(35 \frac{\text{m}^3}{\text{s}}\right)}{4.37 \text{ cm}} + \frac{(12 \text{ cm})\left(10 \frac{\text{m}^3}{\text{s}}\right)}{4.37 \text{ cm}}$$
$$= 67.5 \text{ m}^3/\text{s}$$

Customary U.S. Solution

(a) Plot the stream gauging data.

The total runoff is the area under the curve, found by multiplying the total runoff by the rainfall data interval. This is equivalent to summing the areas of each rectangle of the histogram.

$$V = \left(9500 \frac{\text{ft}^3}{\text{sec}}\right)(3 \text{ hr})\left(3600 \frac{\text{sec}}{\text{hr}}\right)$$
$$= 1.026 \times 10^8 \text{ ft}^3$$

The watershed drainage area is

$$A_d = (25 \text{ mi}^2)\left(5280 \frac{\text{ft}}{\text{mi}}\right)^2$$
$$= 6.97 \times 10^8 \text{ ft}^2$$

The average precipitation is calculated from Eq. 20.21.

$$P = \frac{V}{A_d}$$
$$= \frac{(1.026 \times 10^8 \text{ ft}^3)\left(12 \frac{\text{in}}{\text{ft}}\right)}{6.97 \times 10^8 \text{ ft}^2}$$
$$= 1.766 \text{ in}$$

The unit hydrograph has the same shape as the actual hydrograph with all ordinates reduced by a factor of 1.766.

(b) To find the flow at $t = 15$ hr, add the contributions from each storm. For the 2 in storm, the contribution is the 15 hr runoff multiplied by its scaling factors; for the 5 in storm, the contribution is the 15 hr − 12 hr = 3 hr runoff multiplied by its scaling factors.

$$Q = \frac{(2 \text{ in})\left(1200 \frac{\text{ft}^3}{\text{sec}}\right)}{1.766 \text{ in}} + \frac{(5 \text{ in})\left(400 \frac{\text{ft}^3}{\text{sec}}\right)}{1.766 \text{ in}}$$
$$= 2492 \text{ ft}^3/\text{sec}$$

11. SCS SYNTHETIC UNIT HYDROGRAPH

If a watershed is ungauged such that no historical records are available to produce a unit hydrograph, the *synthetic hydrograph* can still be reasonably approximated. The process of developing a synthetic hydrograph is known as *hydrograph synthesis.*

Pioneering work was done in 1938 by Snyder, who based his analysis on Appalachian highland watersheds with areas of 10 to 10,000 mi^2. Snyder's work has been largely replaced by more sophisticated analyses, including the SCS methods.

The U.S. Soil Conservation Service (SCS) developed a synthetic unit hydrograph based on the *curve number*, CN. The method was originally intended for use with rural watersheds up to 2000 ac, but it appears to be applicable for urban conditions up to 4000 to 5000 ac.

In order to draw the SCS synthetic unit hydrograph, it is necessary to calculate the time to peak flow (t_p) and the peak discharge (Q_p). Provisions for calculating both of these parameters are included in the method.

$$t_p = 0.5t_R + t_l \qquad 20.22$$

t_R in Eq. 20.22 is the storm duration (i.e., of the rainfall). t_l in Eq. 20.22 is the *lag time* (i.e., the time from the centroid of the rainfall distribution to the peak

discharge). Lag time can be determined from correlations with geographical region and drainage area or calculated from Eq. 20.23. Although Eq. 20.23 was developed for natural watersheds, limited studies of urban watersheds indicate that it does not change significantly for urbanized watersheds. S in Eq. 20.23 is the soil water storage capacity in inches, computed as a function of the curve number. (See Eq. 20.43.)

$$t_l = \frac{L_{o,\text{ft}}{}^{0.8}(S+1)^{0.7}}{1900\sqrt{S_{\text{percent}}}} \qquad 20.23$$

The peak runoff is calculated as

$$Q_p = \frac{0.756A_{d,\text{ac}}}{t_p} \qquad 20.24$$

$$Q_p = \frac{484A_{d,\text{mi}^2}}{t_p} \qquad 20.25$$

Q_p and t_p only contribute one point to the construction of the unit hydrograph. To construct the remainder, Table 20.3 must be used. Using time as the independent variable, selections of time (different from t_p) are arbitrarily made, and the ratio t/t_p is calculated. The curve is then used to obtain the ratio of Q_t/Q_p.

12. SCS SYNTHETIC UNIT TRIANGULAR HYDROGRAPH

The SCS unit triangular hydrograph is shown in Fig. 20.14. It is found from the peak runoff, the time to peak, and the duration of runoff. Peak runoff, Q_p, is found from Eq. 20.24 or 20.25. Time to peak and duration are correlated with the time of concentration. These are generalizations that apply to specific storm and watershed types.

Equation 20.26 can be used to estimate the time to peak.

$$t_p = 0.5t_R + t_l \qquad 20.26$$

$$t_l \approx 0.6t_c \qquad 20.27$$

Alternatively, the time to peak has been roughly correlated to the time of concentration.

$$t_p = 0.67t_c \qquad 20.28$$

The total duration of the unit hydrograph is the sum of time to peak and length of recession limb, assumed to be $1.67t_p$.

$$t_b = t_p + t_{\text{recession}} = t_p + 1.67t_p = 2.67t_p \qquad 20.29$$

Figure 20.15 *Espey Watershed Conveyance Factor*

13. ESPEY SYNTHETIC UNIT HYDROGRAPH

The *Espey method* (1978) calculates the time to peak (t_p in min), peak discharge (Q_p in ft^3/sec), total hydrograph base (t_b in min), and the hydrograph widths at 50% and 75% of the peak discharge rates (W_{50} and W_{75} in min). These values depend on the watershed area (A, in mi^2), main channel flow path length (L in ft), slope (S in ft/ft), roughness, and percent imperviousness (Imp). ϕ is a dimensionless watershed conveyance factor ($0.6 < \phi < 1.3$) that depends on the percent imperviousness and weighted main channel Manning roughness coefficient, n. ϕ is found graphically from Fig. 20.15.

$$t_p = 3.1L^{0.23}S_{\text{decimal}}{}^{-0.25}(\text{Imp}_{\text{percent}})^{-0.18}\phi^{1.57} \quad 20.30$$

$$Q_p = (31.62 \times 10^3)A^{0.96}t_p^{-1.07} \quad 20.31$$

$$t_b = (125.89 \times 10^3)AQ_p^{-0.95} \quad 20.32$$

$$W_{50} = (16.22 \times 10^3)A^{0.93}Q_p^{-0.92} \quad 20.33$$

$$W_{75} = (3.24 \times 10^3)A^{0.79}Q_p^{-0.78} \quad 20.34$$

To use this method, the geometric slope, S, used in Eq. 20.30 is specifically calculated from Eq. 20.35. H is the difference in elevation of points A and B. Point A is the channel bottom a distance $0.2L$ downstream from the upstream watershed boundary. Point B is the channel bottom at the downstream watershed boundary.

$$S_{\text{decimal}} = \frac{H}{0.8L} \quad 20.35$$

The unit hydrograph is drawn by manually "fitting" a smooth curve over the seven computed points. The widths of W_{50} and W_{75} are allocated in a 1:2 ratio to the rising and falling hydrograph limbs, respectively. After the curve is drawn, it is adjusted to be a unit hydrograph. The resulting curve is sometimes referred to as an *Espey 10-minute unit hydrograph.*

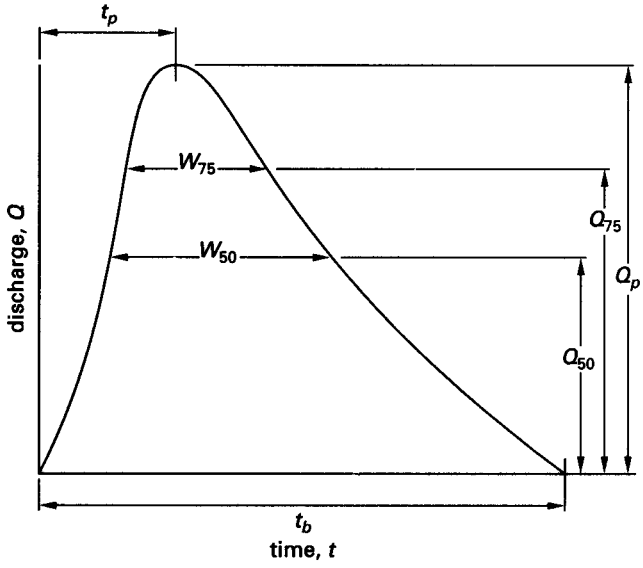

Figure 20.16 *Espey Synthetic Hydrograph*

14. HYDROGRAPH SYNTHESIS

If a storm's duration is not the same or close to the hydrograph base length, the unit hydrograph cannot be used to predict runoff. For example, the runoff from a 6 hr storm cannot be predicted from a unit hydrograph derived from a 2 hr storm. However, the technique of hydrograph synthesis can be used to construct the hydrograph of the longer storm from the unit hydrograph of a shorter storm.

A. Lagging Storm Method

If a unit hydrograph for a storm of duration t_R is available, the *lagging storm method* can be used to construct the hydrograph of a storm whose duration is a whole multiple of t_R. For example, a 6 hr storm hydrograph can be constructed from a 2 hr unit hydrograph.

Let the whole multiple number be n. To construct the longer hydrograph, draw n unit hydrographs, each separated by time t_R. Then add the ordinates to obtain a hydrograph for an nt_R duration storm. Since the total rainfall from this new hydrograph is n inches (having been constructed from n unit hydrographs), the curve will have to be reduced (i.e., divided) by n everywhere to produce a unit hydrograph.

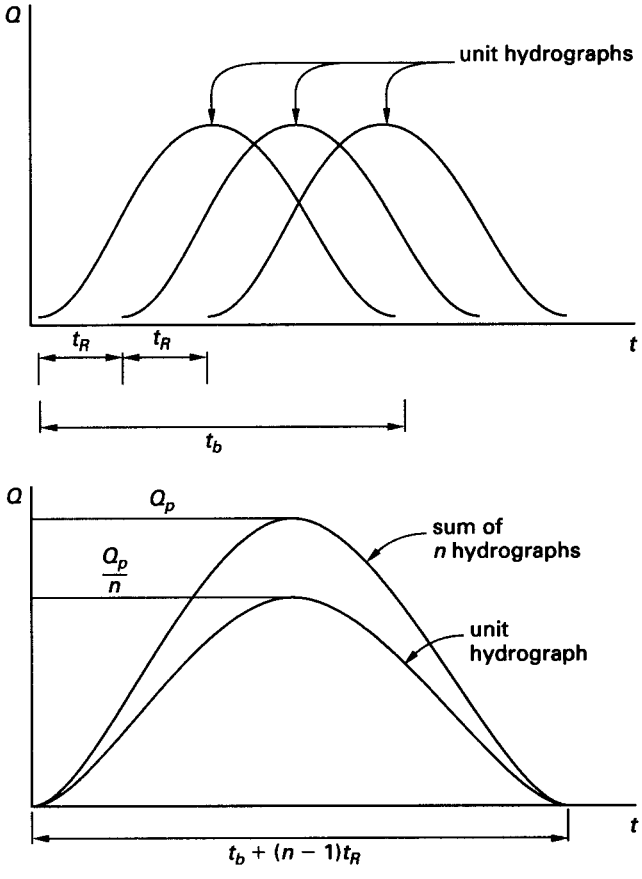

Figure 20.17 *Lagging Storm Method*

B. S-Curve Method

The *S-curve method* can be used to construct hydrographs from unit hydrographs with longer or shorter durations, even when the storm durations are not multiples. This method begins by adding the ordinates of many unit hydrographs, each lagging the other by time t_R, the duration of the storm that produced the unit hydrograph. After a sufficient number of lagging unit hydrographs have been added together, the accumulation will level off and remain constant. At that point, the lagging can be stopped. The resulting accumulation is known as an S-curve.

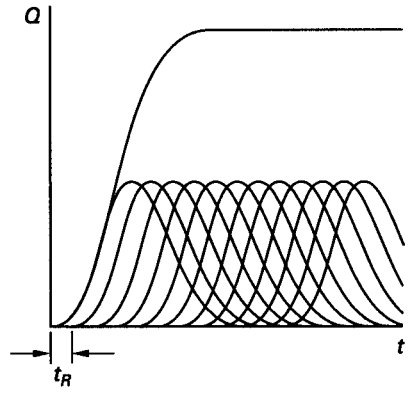

Figure 20.18 *Constructing the S-Curve*

If two S-curves are drawn, one lagging the other by time $t_{R'}$, the area between the two curves represents a hydrograph area for a storm of duration t'_R. The differences between the two curves can be plotted and scaled to a unit hydrograph by multiplying by the ratio of (t_R/t'_R).

15. PEAK RUNOFF FROM THE RATIONAL METHOD

Although total runoff volume is required for reservoir and dam design, the instantaneous peak runoff is needed to size culverts and storm drains.

The *rational formula* ("method," "equation," etc.), Eq. 20.36, for peak discharge has been in widespread use in the United States since the early 1900s.[3] It is applicable to small areas (i.e., less than several hundred acres or so), but is seldom used for areas greater than 1 to 2 mi^2. The intensity used in Eq. 20.36 depends on the time of concentration and the degree of protection desired (i.e., the recurrence interval).[4]

$$Q_p = CIA_d \qquad 20.36$$

[3]In England, the rational equation is known as the *Lloyd-Davies equation.*

[4]When using intensity-duration-frequency curves to size storm sewers, culverts, and other channels, it is assumed that the frequencies and probabilities of flood damage and storms are identical. This is not generally true, but the assumption is usually made anyway.

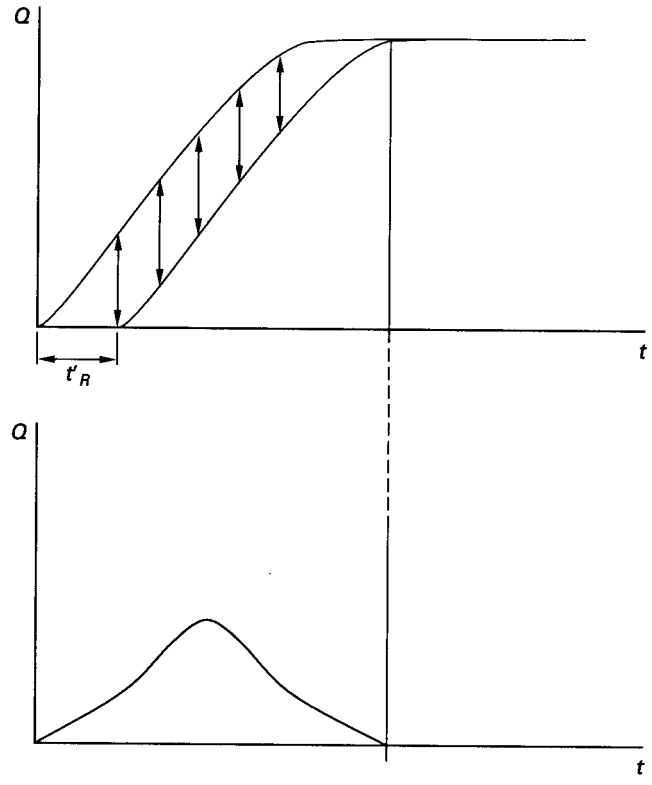

Figure 20.19 *Using S-Curves to Construct a t′ Hydrograph*

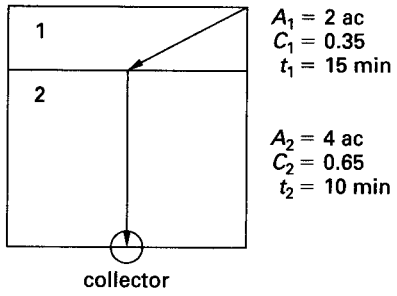
Since A_d is in acres, Q_p is in ac-in/hr. However, Q_p is taken as ft^3/sec since the conversion factor between these two units is 1.008.

Typical values of C coefficients are found in App. 20.A. If more than one area contributes to the runoff, the coefficient is weighted by the areas.



Accurate values of the C coefficient depend not only on the surface cover and soil type, but also on the recurrence interval, antecedent moisture content, rainfall intensity, drainage area, slope, and fraction of imperviousness. These factors have been investigated and quantified by Rossmiller (1981), who correlated these effects with the SCS curve number. The Schaake, et. al. (1967), equation developed at Johns Hopkins University was intended for use in urban areas, correlating the impervious fraction and slope.

$$C = 0.14 + 0.65(\text{Imp}_{\text{decimal}}) + 0.05S_{\text{percent}} \qquad 20.37$$

The rational method assumes that rainfall occurs at a constant rate. If this is true, then the peak runoff will occur when the entire drainage area is contributing to surface runoff, which will occur at t_c. Other assumptions include (a) the recurrence interval of the peak flow is the same as for the design storm, (b) the runoff coefficient is constant, and (c) the rainfall is spatially uniform over the drainage area.

Example 20.5

Two adjacent fields, as shown, contribute runoff to a collector whose capacity is to be determined. The storm intensity after 25 min is 3.9 in/hr. Use the rational method to calculate the peak flow.

Solution

The overland flow time is given for both areas. The time for water from the farthest corner to reach the collector is

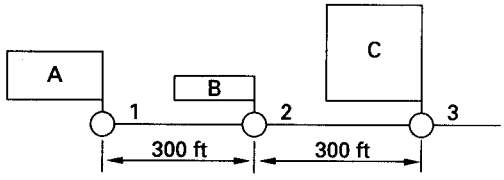
$$t_c = 15 \text{ min} + 10 \text{ min} = 25 \text{ min}$$

The runoff coefficients are given for each area. Since we want to size the pipe carrying the total runoff, the coefficients are weighted by their respective contributing areas.

$$C = \frac{(2 \text{ ac})(0.35) + (4 \text{ ac})(0.65)}{2 \text{ ac} + 4 \text{ ac}}$$
$$= 0.55$$

The intensity after 25 min was given as 3.9 in/hr.

The total area is 4 ac + 2 ac = 6 ac.



The peak flow is found from Eq. 20.36.

$$Q_p = CIA_d = (0.55)\left(3.9 \frac{\text{in}}{\text{hr}}\right)(6 \text{ ac})$$
$$= 12.9 \text{ ac-in/hr } (ft^3/sec)$$

Example 20.6

Three watersheds contribute runoff to a storm drain. The watersheds have the following characteristics.

watershed	area (ac)	overland flow time (min)	C
A	10	20	0.3
B	2	5	0.7
C	15	25	0.4

The instantaneous rainfall intensity (in/hr) for the area and specified storm frequency is

$$I = \frac{115}{t_c + 15}$$

The collector inlets are 300 ft apart. The pipe slope is 0.009. The Manning roughness coefficient is 0.015. Assume the flow velocity is 5 ft/sec in all sections. The storm duration is long enough to permit all three areas to contribute to the combined flow through section 3. (a) What should be the pipe size in section 2? (b) What is the maximum flow through section 3?

Solution

The maximum flow occurs when the overland flow from both areas A and B have reached the second manhole. The time of concentration for area A is the time of concentration to the first manhole plus the travel time in pipe section 1.

$$\begin{aligned} t_c &= 20 \text{ min} + \frac{300 \text{ ft}}{5 \frac{\text{ft}}{\text{sec}}} \left(\frac{1}{60 \frac{\text{sec}}{\text{min}}}\right) \\ &= 21 \text{ min} \end{aligned}$$

The time of concentration for area B is 5 min. The pipe in section 2 should be sized for flow at 21 min.

$$\begin{aligned} I &= \frac{115}{t_c + 15} = \frac{115}{21 + 15} \\ &= 3.19 \text{ in/hr} \end{aligned}$$

Use the sum of the CA values in Eq. 20.36.

$$\begin{aligned} \sum CA &= (0.3)(10 \text{ ac}) + (0.7)(2 \text{ ac}) \\ &= 4.4 \text{ ac} \end{aligned}$$

Use the rational formula, Eq. 20.36.

$$\begin{aligned} Q = \sum CA_d I &= (4.4 \text{ ac}) \left(3.19 \frac{\text{in}}{\text{hr}}\right) \\ &= 14.0 \text{ ac-in/hr } (\text{ft}^3/\text{sec}) \end{aligned}$$

This value of Q should be used to design section 2 of the pipe. If the pipe is assumed to flow full, from Eq. 19.16,

$$\begin{aligned} D &= 1.33 \left(\frac{nQ}{\sqrt{S_{\text{decimal}}}}\right)^{\frac{3}{8}} \\ &= (1.33) \left(\frac{(0.015)\left(14.0 \frac{\text{ft}^3}{\text{sec}}\right)}{\sqrt{0.009}}\right)^{\frac{3}{8}} \\ &= 1.79 \text{ ft} \quad \text{[round to 2.0 ft]} \end{aligned}$$

The maximum flow through section 3 occurs when the overland flow from plots A, B, and C reach the third manhole.

For plot A,

$$t_c = 20 \text{ min} + 1 \text{ min} + 1 \text{ min} = 22 \text{ min}$$

For plot B,

$$t_c = 5 \text{ min} + 1 \text{ min} = 6 \text{ min}$$

For plot C,

$$t_c = 25 \text{ min}$$

The maximum runoff will occur 25 min after the start of the storm.

$$I = \frac{115}{25 + 15} = 2.875 \text{ in/hr}$$

The sum of the CA values is

$$\begin{aligned} \sum CA &= (0.3)(10 \text{ ac}) + (0.7)(2 \text{ ac}) + (0.4)(15 \text{ ac}) \\ &= 10.4 \text{ ac} \\ Q = \sum CA_d I &= (10.4 \text{ ac}) \left(2.875 \frac{\text{in}}{\text{hr}}\right) \\ &= 29.9 \text{ ac-in/hr } (\text{ft}^3/\text{sec}) \end{aligned}$$

16. SCS CURVE NUMBER

Several methods of calculating total and peak runoff have been developed over the years by the U.S. Soil Conservation Service. These methods have generally been well correlated with actual experience, and the SCS methods have become dominant in the United States.

The SCS methods classify the land use and soil type by a single parameter called the *curve number*, CN. This method can be used for any size homogeneous watershed with a known percentage of imperviousness. If the watershed varies in soil type or in cover, it generally should be divided into regions to be analyzed separately. A composite curve number can be calculated by weighting the curve number for each region by its area. Alternatively, the runoffs from each region can be calculated separately and added.

The SCS method of using precipitation records and an assumed distribution of rainfall to construct a synthetic storm is based on several assumptions. First, a type II storm is assumed. Type I storms, which drop most of their precipitation early, are applicable to Hawaii, Alaska, and the coastal side of the Sierra Nevada and Cascade mountains in California, Oregon, and Washington. Type II distributions are typical of the rest of the United States, Puerto Rico, and the Virgin Islands.

This method assumes that initial abstraction (depression storage, evaporation, and interception losses) is equal to 20% of the storage capacity.

$$I_a = 0.2S \qquad 20.38$$

For there to be any runoff at all, the gross rain must equal or exceed the initial abstraction.

$$P \geq I_a \qquad 20.39$$

The storage capacity must be great enough to absorb the initial abstraction plus the infiltration.

$$S \geq I_a + F \qquad 20.40$$

The following steps constitute the SCS method.

step 1: Classify the soil into a *hydrologic soil group* (HSG) according to its infiltration rate. Soil is classified into HSG A (low runoff potential) through D (high runoff potential).

Type A: High infiltration rates (> 0.30 in/hr) even if thoroughly saturated; chiefly deep sands and gravels with good drainage and high moisture transmission. In urbanized areas, this category includes sand, loamy sand, and sandy loam.

Type B: Moderate infiltration rates if thoroughly wetted (0.15 to 0.30 in/hr), moderate rates of moisture transmission, and consisting chiefly of coarse to moderately fine textures. In urbanized areas, this category includes silty loam and loam.

Type C: Slow infiltration rates (0.05 to 0.15 in/hr) if thoroughly wetted, and slow moisture transmission; soils having moderately fine to fine textures or that impede the downward movement of water. In urbanized areas, this category includes sandy clay loam.

Type D: Very slow infiltration rates (less than 0.05 in/hr) if thoroughly wetted, very slow water transmission, and consisting primarily of clay soils with high potential for swelling; soils with permanent high water tables; or soils with an impervious layer near the surface. In urbanized areas, this category includes clay loam, silty clay loam, sandy clay, silty clay, and clay.

(Note that as a result of urbanization, the underlying soil may be disturbed or covered by a new layer. The original classification will no longer be applicable, and the "urbanized" soil HSGs are applicable.)

step 2: Determine the preexisting soil conditions. The soil condition is classified into *antecedent runoff conditions* (ARC) I through III.[5] Generally, "average" conditions (ARC II) are assumed.

ARC I: Dry soils, prior to or after plowing or cultivation, or after periods without rain.

ARC II: Typical conditions existing before maximum annual flood.

ARC III: Saturated soil due to heavy rainfall (or light rainfall with freezing temperatures) during 5 days prior to storm.

step 3: Classify *cover type* and hydrologic condition of the soil-cover complex. For pasture, range, row crops, arid, and semiarid lands, the SCS method includes additional tables to classify the cover and hydrologic conditions. In order to use these tables, it is necessary to characterize the surface coverage. The condition is "good" if it is lightly grazed or has plant cover over 75% or more of its area. The condition is "fair" if plant coverage is 50 to 75% or not heavily grazed. The condition is "poor" if the area is heavily grazed, has no mulch, or has plant cover over less than 50% of the area.

step 4: Use Table 20.4 or Table 20.5 to determine the *curve number*, CN, corresponding to the soil classification for ARC II.

step 5: If the soil is ARC I or ARC III, convert the curve number from step 4 using Eq. 20.41 or 20.42 and rounding up.

$$\mathrm{CN_I} = \frac{4.2\mathrm{CN_{II}}}{10 - 0.058\mathrm{CN_{II}}} \qquad 20.41$$

$$\mathrm{CN_{III}} = \frac{23\mathrm{CN_{II}}}{10 + 0.13\mathrm{CN_{II}}} \qquad 20.42$$

step 6: If any significant fraction of the watershed is impervious (i.e., CN = 98), or if the watershed consists of areas with different curve numbers, calculate the composite curve number by weighting by the runoff areas (same as weighting by the impervious and pervious fractions). If the watershed's impervious fraction is different from the value implicit in step 3's classification, or if the impervious area is not connected directly to a storm drainage system, the SCS method includes direct and graphical adjustments.

step 7: Estimate the time to concentration of the watershed.[6]

step 8: Determine the *gross (total) rainfall*, P, from the storm. To do this, it is necessary to assume the storm length and recurrence interval. It is a characteristic of the SCS methods to use a 24 hr storm. Maps from the

[5]The *antecedent runoff condition* (ARC) may also be referred to as the *antecedent moisture condition* (AMC).

[6]The SCS method uses T_c, not t_c, as the symbol for time of concentration.

[a] *Crop residue cover* applies only if residue is on at least 5% of the surface throughout the year.
[b] Hydrologic condition is based on a combination of factors that affect infiltration and runoff, including (a) density and canopy of vegetative areas, (b) amount of year-round cover, (c) amount of grass or close-seeded legumes in rotations, (d) percent of residue cover on the land surface (good $\geq$ 20%), and (e) degree of surface roughness.
Poor: Factors impair infiltration and tend to increase runoff.
Good: Factors encourage average and better-than-average infiltration and tend to decrease runoff.

Reprinted from *Urban Hydrology for Small Watersheds*, Technical Release TR 55, United States Department of Agriculture, Soil Conservation Service, Table 2-b, 1986.

U.S. Weather Bureau can be used to read gross point rainfalls for storms with frequencies from 1 to 100 years.[7]

step 9: Multiply the gross rain point value from step 8 by a factor from Fig. 20.20 to make the gross rain representative of larger areas. This is the *areal rain.*

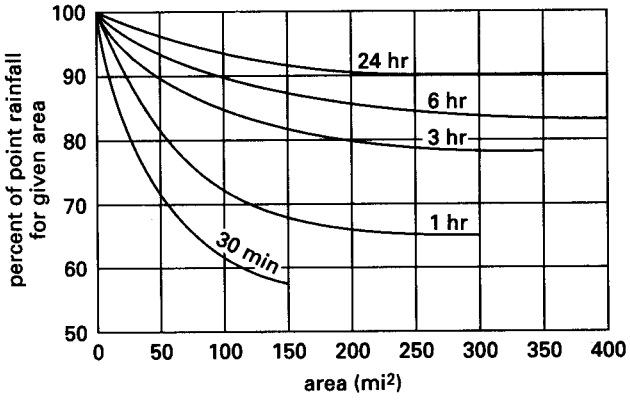

Figure 20.20 *Point to Areal Rain Conversion Factors*

step 10: The SCS method assumes that infiltration follows an exponential decay curve with time. Storage capacity of the soil (i.e., the potential maximum retention after runoff begins), S, is calculated from the curve number by using Eq. 20.43.

$$S = \frac{1000}{\text{CN}} - 10 \qquad 20.43$$

step 11: Calculate the total runoff (net rain, precipitation excess, etc.) in inches from the areal rain. Equation 20.44 subtracts losses from interception, storm period evaporation, depression storage, and infiltration from the *gross rain* to obtain the *net rain.* (Equation 20.44 can be derived from the water balance equation, Eq. 20.2.)

$$Q_{\text{inches}} = \frac{(P_g - I_a)^2}{P_g - I_a + S} = \frac{(P_g - 0.2S)^2}{P_g + 0.8S} \qquad 20.44$$

17. SCS GRAPHICAL PEAK DISCHARGE METHOD

Two SCS methods are available for calculating the peak discharge. When a full hydrograph is not needed, the so-called graphical method can be used. If a hydrograph is needed, the tabular method can be used.[8] The graphical method is applicable when (a) CN > 40, (b) 0.1 hr $< t_c <$ 10 hr, (c) the watershed is relatively homogeneous or uniformly mixed, (d) all streams have the same time of concentration, and (e) there is no interim storage along the stream path.

Equation 20.45 is the SCS peak discharge equation. q_p is the peak discharge (ft^3/sec), q_u is the unit peak discharge (cubic feet per square mile per inch of runoff, csm/in), A_{mi^2} is the drainage area in mi^2, Q_{inches} is the runoff (in), and F_p is a pond and swamp adjustment factor.

$$q_p = q_u A_{\text{mi}^2} Q F_p \qquad 20.45$$

The graphical method begins by obtaining the design 24 hr rainfall, P, for the area. Total runoff, Q, and the curve number, CN, are determined as in Sec. 16. Then, the initial abstraction, I_a, is obtained from Table 20.6, and the ratio I_a/P is calculated. Next, SCS curves are entered with t_c and the I_a/P ratio to determine the runoff in cubic feet per square mile per inch of runoff (csm/in). The appropriate pond and swamp adjustment factor is selected from the SCS literature. ($F_p = 1$ if there are no ponds or swamps.)

Table 20.6 *Initial Abstraction versus Curve Number*

curve number	I_a (in)	curve number	I_a (in)
40	3.000	70	0.857
41	2.878	71	0.817

[7] *Rainfall Frequency Atlas of the United States*, U.S. Weather Bureau, Technical Paper 40.

[8] The graphical and tabular methods both rely on graphs and tables that are contained in TR-55. These graphs and tables are not included in this chapter. The SCS tabular method is also not described in this book.

18. RESERVOIR SIZING: MODIFIED RATIONAL METHOD

An effective method of preventing flooding is to store surface runoff temporarily. After the storm is over, the stored water can be gradually released. An *impounding reservoir* (*retention watershed* or *detention watershed*) is a watershed used to store excess flow from a stream or river. The stored water is released when the stream flow drops below the minimum level that is needed to meet water demand. The *impoundment depth* is the design depth. Finding the impoundment depth is equivalent to finding the design storage capacity of the reservoir.

The purpose of a *reservoir sizing* (*reservoir yield*) analysis is to determine the proper size of a reservoir or dam, or to evaluate the ability of an existing reservoir to meet water demands.

The volume of a reservoir needed to hold streamflow from a storm is simply the total area of the hydrograph. Similarly, when comparing two storms, the incremental volume needed is simply the difference in the areas of their two hydrographs.

Poertner's (1974) *modified rational method* can be used to design detention storage facilities for small areas (up to 20 ac). A trapezoidal hydrograph is constructed with the peak flow calculated from the Rational equation. The total hydrograph base (i.e., the total duration of surface runoff) is the storm duration plus the time to concentration. The durations of the rising and falling limbs are both taken as t_c.

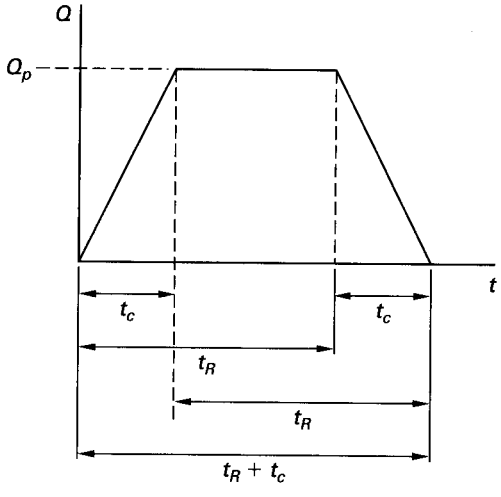

Figure 20.21 *Modified Rational Method Hydrograph*

To size a detention watershed using this method, a trapezoidal hydrograph is drawn for several storm durations greater than $2t_c$ (e.g., 10, 15, 20, and 30 min). For each of the storm durations, the total rainfall is calculated as the hydrograph area. The difference between the total rainfall and the total released water (calculated as the product of the allowable release rate and the storm duration) is the required storage capacity.

Detention watershed sizing for areas larger than 20 ac should be accomplished using full hydrograph methods in combination with reservoir routing.

19. RESERVOIR SIZING: NONSEQUENTIAL DROUGHT METHOD

The *nonsequential drought method* is somewhat complex, but it has the advantage of giving an estimate of the required reservoir size, rather than merely evaluating a trial size. In the absence of synthetic drought information, it is first necessary to develop intensity-duration-frequency curves from stream flow records.

step 1: Choose a duration. Usually, the first duration used will be 7 days, although choosing 15 days will not introduce too much error.

step 2: Search the streamflow records to find the smallest flow during the duration chosen. (The first time through, for example, find the smallest discharge totaled over any 7 days.) The days do not have to be sequential.

step 3: Continue searching the discharge records to find the next smallest discharge over the number of days in the period. Continue searching and finding the smallest discharges (which gradually increase) until all of the days in the record have been used up. Do not use the same day more than once.

step 4: Give the values of smallest discharge order numbers; that is, give $M = 1$ to the smallest discharge, $M = 2$ to the next smallest, etc.

step 5: For each observation, calculate the recurrence interval as

$$F = \frac{n_y}{M} \qquad 20.46$$

n_y is the number of years of streamflow data that was searched to find the smallest discharges.

step 6: Plot the points as discharge on the y-axis versus F in years on the x-axis. Draw a reasonably continuous curve through the points.

step 7: Return to step 1 for the next duration. Repeat for all of the following durations: 7, 15, 30, 60, 120, 183, and 365 days.

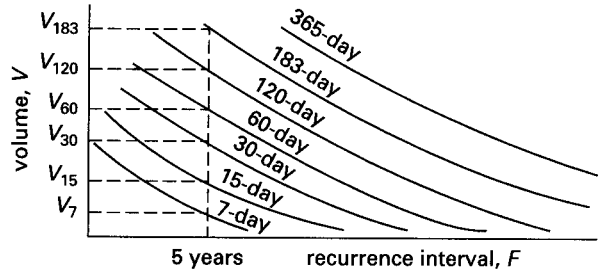

Figure 20.22 *Sample Family of Synthetic Inflow Curves*

A synthetic drought can be constructed for any recurrence interval. For example, if a 5 year drought is to be planned for, the discharges V_7, V_{15}, V_{30}, ..., V_{365} are read from the appropriate curves for $F = 5$ yr.

The next step is to plot the reservoir *mass diagram* (also known as a *Rippl diagram*). This is a simultaneous plot of the cumulative demand (known as *draft*) and cumulative inflow. The mass diagram is used to graphically determine the reservoir storage requirements (i.e., size).

As long as the slopes of the cumulative demand and inflow lines are equal, the water reserve in the reservoir will not change. When the slope of the inflow is less than the slope of the demand, the inflow cannot by itself satisfy the community's water needs, and the reservoir is drawn down to make up the difference. A peak followed by a trough is, therefore, a drought condition.

If the reservoir is to be sized so that the community will not run dry during a drought, the required capacity is the maximum separation between two parallel lines (pseudo-demand lines with slopes equal to the demand rate) drawn tangent to a peak and a subsequent trough. If the mass diagram covers enough time so that multiple droughts are present, the largest separation between peaks and subsequent troughs represents the capacity.

In order for the reservoir to supply enough water during a drought condition, the reservoir must be full prior to the start of the drought. This fact is not represented when the mass diagram is drawn, hence the need to draw a pseudo-demand line parallel to the peak.

After a drought equal to the capacity of the reservoir, the reservoir will again be empty. At the trough, however, the reservoir begins to fill up again. When the cumulative excess exceeds the reservoir capacity, the reservoir will have to "spill" (i.e., release) water. This occurs when the cumulative inflow line crosses the prior peak's pseudo-demand line as shown in Fig. 20.23.

A *flood-control dam* is built to keep water in and must be sized so that water is not spilled. The mass diagram can still be used, but the maximum separation between troughs and subsequent peaks (not peaks followed by troughs) is the required capacity.

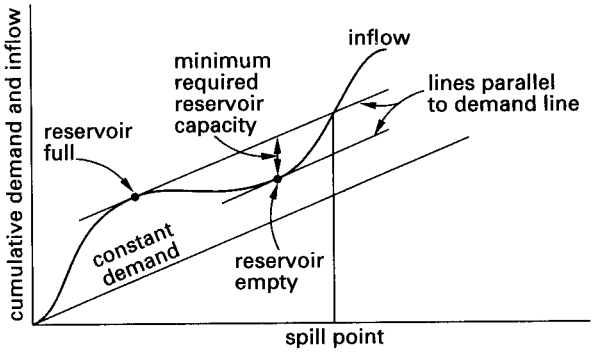

Figure 20.23 *Reservoir Mass Diagram (Rippl Diagram)*

20. RESERVOIR SIZING: RESERVOIR ROUTING

Reservoir routing is the process by which the outflow hydrograph (i.e., the outflow over time) of a reservoir is determined from the inflow hydrograph (i.e., the inflow over time), the initial storage, and other characteristics of the reservoir. The simplest method is to keep track of increments in inflow, storage, and outflow period by period in a tabular simulation. This is the basis of the *storage indication method*, which is basically a bookkeeping process. The validity of this method is dependent on choosing time increments that are as small as possible.

step 1: Determine the starting storage volume, V_n. If the starting volume is zero or considerably different from the average steady-state storage, a large number of iterations will be required before the simulation reaches its steady-state results. A convergence criterion should be determined before the simulation begins.

step 2: For the next iteration, determine the inflow, discharge, evaporation, and seepage. The starting storage volume for the next iteration is found by solving Eq. 20.47.

$$V_{n+1} = V_n + (\text{inflow})_n - (\text{discharge})_n - (\text{seepage})_n - (\text{evaporation})_n \qquad 20.47$$

Repeat step 2 as many times as necessary.

Loss due to seepage is generally very small compared to inflow and discharge, and it is often neglected. Reservoir *evaporation* can be estimated from analytical relationships or by evaluating data from *evaporation pans*. Pan data is extended to reservoir evaporation by the pan coefficient formula. In Eq. 20.48, the summation is taken over the number of days in the simulation period. Units of evaporation are typically in/day. A typical value of C_p is 0.7.

$$E_R = \sum C_p E_p \qquad 20.48$$

Inflow can be taken from actual past history. However, since it is unlikely that history will repeat exactly, the next method is preferred.

21. RESERVOIR ROUTING: STOCHASTIC SIMULATION

The *stochastic simulation* method of reservoir routing is the same as tabular simulation except for the method of determining the inflow. This description uses a *Monte Carlo simulation* technique that is dependent on enough historical data to establish a cumulative inflow distribution. A Monte Carlo simulation is suitable if long

periods are to be simulated. If short periods are to be simulated, the simulation should be performed several times and the results averaged.

step 1: Tabulate or otherwise determine a frequency distribution of inflow quantities.

step 2: Form a cumulative distribution of inflow quantities.

step 3: Multiply the cumulative x-axis (which runs from 0 to 1) by 100 or 1000, depending on the accuracy needed.

step 4: Generate random numbers between 0 and 100 (or 0 and 1000). Use of a random number table (App. 20.B) is adequate for hand simulation.

step 5: Locate the inflow quantity corresponding to the random number from the cumulative distribution x-axis.

Example 20.7

A well-monitored stream has been observed for 50 yr and has the following frequency distribution of total annual discharges.

discharge (units)	frequency (yr)	% of time
0 to 0.5	5	0.10
0.5 to 1.0	21	0.42
1.0 to 1.5	17	0.34
1.5 to 2.0	7	0.14

It is proposed that a dam be placed across the stream to create a reservoir with a capacity of 1.8 units. The reservoir is to support a town that will draw 1.2 units per year. Use stochastic simulation to simulate 10 yr of reservoir operation, assuming it starts filled with 1.5 units.

Solution

step 1: The frequency distribution is given.

steps 2 and 3: Make a table to form the cumulative distribution with multiplied frequencies.

discharge	cumulative frequency	cumulative frequency × 100
0 to 0.5	0.10	10
0.5 to 1.0	0.52	52
1.0 to 1.5	0.86	86
1.5 to 2.0	1.00	100

step 4: From App. 20.B, choose ten 2-digit numbers. The starting point within the table is arbitrary, but the numbers must come sequentially from a row or column. Use the first row for this simulation.

78, 46, 68, 33, 26, 96, 58, 98, 87, 27

step 5: For the first year, the random number is 78. Since 78 is greater than 52 but less than 86, the inflow is in the 1.0 to 1.5 unit range. The midpoint of this range is taken as the inflow, which would be 1.25. The reservoir volume after the first year would be $1.5 + 1.25 - 1.20 = 1.55$. The remaining years can be similarly simulated.

year	starting volume	+ inflow	− usage	= ending volume	+ spill
1	1.5	1.25	1.2	1.55	
2	1.55	0.75	1.2	1.1	
3	1.1	1.25	1.2	1.15	
4	1.15	0.75	1.2	0.7	
5	0.7	0.75	1.2	0.25	
6	0.25	1.75	1.2	0.8	
7	0.8	1.25	1.2	0.85	
8	0.85	1.75	1.2	1.4	
9	1.4	1.75	1.2	1.95	0.15
10	1.8	0.75	1.2	1.35	

No shortages are experienced; one spill is required.

22. STORMWATER/WATERSHED MANAGEMENT MODELING

Flood routing and *channel routing* are terms used to describe the passage of a flood or runoff wave through a complex system. Due to flow times, detention, and processing, the wave front appears at different points in a system at different times. The ability to simulate flood, channel, and reservoir routing is particularly useful when evaluating competing features (e.g., treatment, routing, storage options).

The interaction of stormwater features (e.g., watersheds, sewers and storm drains, detention watersheds, treatment facilities) during and after a storm is complex. In addition to continuity considerations, the interaction is affected by hydraulic considerations (e.g., the characteristics of the flow paths) and topography (e.g., the elevation changes from point to point).

Many computer programs have been developed to predict the performance of such complex systems. These simulation programs vary considerably in complexity, degree of hydraulic detail, length of simulation interval, and duration of simulation study. The Environmental Protection Agency (EPA) Stormwater Management Model is a well-known micro-scale model, particularly well-suited to areas with a high impervious fraction. The Army Corp of Engineers' STORM model is a macro-scale model. The SCS TR-20 program is consistent with other SCS methodology.

23. FLOOD CONTROL CHANNEL DESIGN

For many years, the traditional method of flood control was *channelization*, converting a natural stream to a uniform channel cross section. However, this method

does not always work as intended and may fail at critical moments. Some of the reasons for reduced capacities are sedimentation, increased flow resistance, and inadequate maintenance.

The design of artificial channels is often based on clear-water hydraulics without sediment. However, the capacity of such channels is greatly affected by *sedimentation.* Silting and sedimentation can double or triple the Manning roughness coefficient. Every large flood carries appreciable amounts of bed load, significantly increasing the composite channel roughness. Also, when the channel is unlined, scour and erosion can significantly change the channel cross-sectional area.

To minimize cost and right-of-way requirements, shallow supercritical flow is often intended when the channel is designed. However, supercritical flow can occur only with low bed and side roughness. When the roughness increases during a flood, the flow shifts back to deeper, slower-moving subcritical flows.

Debris carried downstream by floodwaters can catch on bridge pilings and culverts, obstructing the flow. Actual flood profiles can resemble a staircase consisting of a series of backwater pools behind obstructed bridges, rather than a uniformly sloping surface. In such situations, the most effective flood control method may be replacement of bridges or improved emergency maintenance procedures to remove debris.

Vegetation and other debris that collects during dry periods in the flow channel reduces the flow capacity. Maintenance of channels to eliminate the vegetation is often haphazard.

Lately, increased emphasis in flood control channel design programs has been on "creek protection" and the long-term management of natural channels. Elements of such programs include (a) excavation of a low-flow channel within the natural channel, (b) periodic intervention to keep the channel clear, (c) establishment of a wide floodplain terrace along the channel banks, incorporating wetlands, vegetation, and public-access paths, and (d) planting riparian vegetation and trees along the terrace to slow bank erosion and provide a continuous corridor for wildlife.

PRACTICE PROBLEMS

Hydrographs

1. A 2 h storm over a 111 km^2 area produces a total runoff volume of 4×10^6 m^3 with a peak discharge of 260 m^3/s.

(a) What is the total precipitation?
(A) 1.4 cm
(B) 2.6 cm
(C) 3.6 cm
(D) 4.0 cm

The answer is (C).

(b) What is the unit hydrograph peak discharge?
(A) 72 $m^3/s \cdot cm$
(B) 120 $m^3/s \cdot cm$
(C) 210 $m^3/s \cdot cm$
(D) 260 $m^3/s \cdot cm$

The answer is (A).

(c) If a 2 h storm producing 6.5 cm of runoff is to be used to design a culvert, what is the design flood hydrograph volume?
(A) 4.0×10^6 m^3
(B) 7.2×10^6 m^3
(C) 2.6×10^7 m^3
(D) 3.6×10^7 m^3

The answer is (B).

(d) What is the design discharge?
(A) 89 m^3/s
(B) 130 m^3/s
(C) 260 m^3/s
(D) 470 m^3/s

The answer is (D).

(e) The recurrence interval of the 6.5 cm storm is 50 yr, and the culvert is to be designed for a 30 yr life. What is the probability that the capacity will be exceeded during the design life?
(A) 0%
(B) 33%
(C) 45%
(D) 92%

The answer is (C).

(f) The unit hydrograph represents water flowing into a stream from
I. base flow
II. evapotranspiration
III. overland flow
IV. surface flow
V. interflow
(A) I only
(B) I and III
(C) II, III, and IV
(D) III, IV, and V

The answer is (D).

Use the following information for parts (g) through (j).

Stream discharges recorded during a 3 h storm on a 40 km^2 watershed are as follows.

t (h)	$Q\left(\frac{m^3}{s}\right)$
0	17
1	16
2	48
3	90
4	108
5	85
6	58
7	38
8	26
9	20
10	18
11	17
12	16

(g) What is the unit hydrograph peak discharge from surface runoff for this 3 h storm?

(A) 5.2 $m^3/s \cdot cm$
(B) 29 $m^3/s \cdot cm$
(C) 65 $m^3/s \cdot cm$
(B) 120 $m^3/s \cdot cm$

The answer is (B).

(h) What is the peak discharge for a 6 h storm producing 5 cm of runoff in this watershed?

(A) 92 m^3/s
(B) 140 m^3/s
(C) 170 m^3/s
(D) 300 m^3/s

The answer is (A).

(i) What is the peak discharge for a 5 h storm producing 5 cm of runoff in this watershed?

(A) 63 $m^3/s \cdot cm$
(B) 90 $m^3/s \cdot cm$
(C) 110 $m^3/s \cdot cm$
(D) 260 $m^3/s \cdot cm$

The answer is (C).

(j) What is the design flood hydrograph volume for a 5 h storm producing 5 cm of runoff in this watershed?

(A) 1.3×10^4 m^3
(B) 4.0×10^5 m^3
(C) 8.3×10^5 m^3
(D) 2.0×10^6 m^3

The answer is (D).

2. (*Time limit: one hour*) A stream gauging station recorded the following discharges from a 1.2 mi^2 drainage area after a storm.

t (hr)	$Q\left(\frac{ft^3}{sec}\right)$
0	102
1	99
2	101
3	215
4	507
5	625
6	455
7	325
8	205
9	145
10	100
11	70
12	55
13	49
14	43
15	38

(a) Draw the actual hydrograph. (b) Separate the groundwater and surface water. (c) Draw the unit hydrograph.

(d) What is the length of the direct runoff recession limb?

(A) 5 hr
(B) 6 hr
(C) 10 hr
(D) 13 hr

The answer is (B).

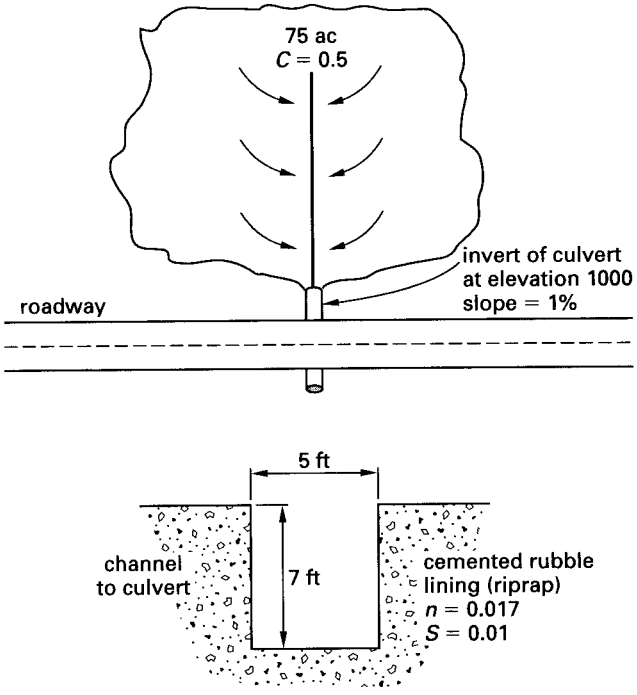
Rational Equation

3. A 0.5 mi^2 drainage area has a suggested runoff coefficient of 0.6 and a time of concentration of 60 min. The drainage area is in Steel region #3, and a 10 yr storm is to be used for design purposes. What is the peak runoff?

(A) 310 ft^3/sec
(B) 390 ft^3/sec
(C) 460 ft^3/sec
(D) 730 ft^3/sec

The answer is (B).

4. Four contiguous 5 ac watersheds are served by an adjacent 1200 ft storm drain (n = 0.013 and slope = 0.005). Inlets to the storm drain are placed every 300 ft along the storm drain. The inlet time for each area served by an inlet is 15 min, and the area's runoff coefficient is 0.55. A storm to be used for design purposes has the following characteristics (I is in in/hr, t is in min).



$$I = \frac{100}{t_c + 10}$$

All flows are maximum, and all pipe sizes are available. n is constant. What is the diameter of the last section of storm drain?

(A) 28 in
(B) 32 in
(C) 34 in
(D) 42 in

The answer is (C).

5. (*Time limit: one hour*) A 75 ac urbanized section of land drains into a rectangular 5 ft by 7 ft channel that directs runoff through a round culvert under a roadway. The culvert is concrete and is 60 in in diameter. It is 36 ft long and placed on a 1% slope.

It is desired to evaluate the culvert design based on a 50 yr storm. It is known that the time of concentration to the entrance of the culvert is 30 min. The corresponding rainfall intensity is 5.3 in/hr.

(a) If the minimum road surface elevation is 1010 ft, will the road surface be flooded?

(A) yes; the culvert needs 10 ft^3/sec additional capacity
(B) yes; the culvert needs 70 ft^3/sec additional capacity
(C) no; the culvert has 20 ft^3/sec excess capacity
(D) no; the culvert has 70 ft^3/sec excess capacity

The answer is (D).

(b) What is the depth of flow elevation upstream at the culvert entrance after 30 min?

(A) 2.7 ft
(B) 3.1 ft
(C) 3.6 ft
(D) 4.1 ft

The answer is (C).

(c) Assuming n varies with depth of flow, what is the depth of flow at the culvert exit after 30 min?

(A) 2.7 ft
(B) 3.1 ft
(C) 3.6 ft
(D) 4.1 ft

The answer is (C).

Hydrograph Synthesis

6. (*Time limit: one hour*) A standard 4 hr storm produces 2 in net of runoff. A stream gauging report is produced from successive sampling every few hours. Two weeks later, the first 4 hr of an 8 hr storm over the same watershed produces 1 in of runoff. The second 4 hr produces 2 in of runoff. Neglecting ground water, draw a hydrograph of the 8 hr storm.

t (hr)	$Q\left(\frac{ft^3}{sec}\right)$
0	0
2	100
4	350
6	600
8	420
10	300
12	250
14	150
16	100

20	50
22	–
24	0

Reservoir Sizing

7. A class A evaporation pan located near a reservoir shows a 1 day evaporation loss of 0.8 in. If the pan coefficient is 0.7, what is the approximate evaporation loss in the reservoir?

(A) 0.56 in
(B) 0.63 in
(C) 0.98 in
(D) 1.1 in

The answer is (A).

8. A reservoir has a total capacity of 7 volume units. At the beginning of a study, the reservoir contains 5.5 units. The monthly demand on the reservoir from a nearby city is 0.7 units. The monthly inflow to the reservoir is normally distributed with a mean of 0.9 units and a standard deviation of 0.2 units. Simulate one year of reservoir operation.

9. Repeat Prob. 8 assuming that the monthly demand on the reservoir is normally distributed with a mean of 0.7 units and a standard deviation of 0.2 units.

10. (*Time limit: one hour*) A reservoir is needed to provide 20 ac-ft of water each month. The inflow for each of 13 representative months is given. The reservoir starts full. Size the reservoir.

month	inflow (ac-ft)
February	30
March	60
April	20
May	10
June	5
July	10
August	5
September	10
October	20
November	90
December	85
January	75
February	50

(A) 40 ac-ft
(B) 60 ac-ft
(C) 90 ac-ft
(D) 120 ac-ft

The answer is (B).

11. (*Time limit: one hour*) A reservoir with a constant draft of 240 MG/mi^2-yr is being designed. The inflow distribution is known.

month	inflow (MG/mi^2)	inflow (m^3/m^2)
January	20	0.029
February	30	0.044
March	45	0.066
April	30	0.044
May	40	0.058
June	30	0.044
July	15	0.022
August	5	0.007
September	15	0.022
October	60	0.088
November	90	0.132
December	40	0.058

(a) What should be the minimum reservoir size?
(A) 25 MG/mi^2
(B) 35 MG/mi^2
(C) 45 MG/mi^2
(D) 65 MG/mi^2

The answer is (A).

(b) When would the reservoir start to spill?
(A) at the end of March
(B) at the end of June
(C) at the end of September
(D) at the end of March and the end of September

The answer is (D).

1. AQUIFERS

Underground water, also known as *subsurface water*, is contained in saturated geological formations known as *aquifers*. Aquifers are divided into two zones by the water table surface. The *vadose zone* is above the elevation of the water table. Pores in the vadose zone may be either saturated or empty. The *phreatic zone* is below the elevation of the water table. Pores are always saturated in the phreatic zone.

An aquifer whose water surface is at atmospheric pressure and that can rise or fall with changes in volume is a *free aquifer*, also known as an *unconfined aquifer*. If a

well is drilled into an unconfined aquifer, the water level in the well will correspond to the water table. Such a well is known as a *gravity well.*

An aquifer that is bounded on all extents is known as a *confined aquifer.* The water in confined aquifers may be under pressure. If a well is drilled into such an aquifer, the water in the well will rise to a height corresponding to the hydrostatic pressure. The *piezometric height* of the rise is

$$H = \frac{p}{\rho g} \quad \text{[SI]} \qquad 21.1(a)$$

$$H = \frac{p}{\gamma} = \frac{p}{\rho} \times \frac{g_c}{g} \quad \text{[U.S.]} \qquad 21.1(b)$$

If the confining pressure is high enough, the water will be expelled from the surface, and the source is known as an *artesian well.*

2. AQUIFER CHARACTERISTICS

Soil moisture content (*water content*), w, can be determined by oven drying a sample of soil and measuring the change in mass.[1] The water content is the ratio of the mass of water to the mass of solids, expressed as a percentage. The water content can also be determined with a *tensiometer*, which measures the vapor pressure of the moisture in the soil.

$$w = \frac{m_w}{m_s} = \frac{m_t - m_s}{m_s} \qquad 21.2$$

The *porosity*, n, of the aquifer is the percentage of void volume to total volume.[2]

$$n = \frac{V_v}{V_t} = \frac{V_t - V_s}{V_t} \qquad 21.3$$

The *void ratio*, e, is

$$e = \frac{V_v}{V_s} = \frac{V_t - V_s}{V_s} \qquad 21.4$$

Void ratio and porosity are related.

$$e = \frac{n}{1 - n} \qquad 21.5$$

Some pores and voids are dead ends or are too small to contribute to seepage. Only the *effective porosity*, n_e, 95 to 98% of the total porosity, contributes to groundwater flow.

The *hydraulic gradient*, i, is the change in hydraulic head over a particular distance. The hydraulic head at a point is determined as the piezometric head at observation wells.

$$i = \frac{\Delta H}{L} \qquad 21.6$$

[1]It is common in civil engineering to use the term "weight" in place of mass. For example, the *water content* would be defined as the ratio of the weight of water to the weight of solids, expressed as a percentage.

[2]The symbol θ is sometimes used for porosity.

3. PERMEABILITY

The flow of a liquid through a permeable medium is affected by both the fluid and the medium. The effects of the medium (independent of the fluid properties) are characterized by the *intrinsic permeability* (*specific permeability*), k. Intrinsic permeability has dimensions of length squared. The *darcy* has been widely accepted as the unit of intrinsic permeability. One darcy is 0.987×10^{-8} cm^2.

For studies involving the flow of water through an aquifer, effects of intrinsic permeability and the water are combined into the *hydraulic conductivity*, also known as the *coefficient of permeability* or simply the *permeability*, K. Hydraulic conductivity can be determined from a number of water-related tests.[3] It has units of length divided by time (i.e., of velocity).

$$K = \frac{k\gamma}{\mu} \qquad 21.7$$

For many years in the United States, hydraulic conductivity was specified in *Meinzer units* (gallons per day per square foot). To avoid confusion related to multiple definitions and ambiguities in these definitions, hydraulic conductivity is now often specified in units of ft/day (m/day).

The coefficient of permeability is proportional to the square of the mean particle diameter.

$$K = CD_{\text{mean}}^2 \qquad 21.8$$

Hazen's empirical formula can be used to calculate an approximate coefficient of permeability for clean, uniform sands. D_{10} is the effective size in mm.

$$K_{\text{cm/s}} \approx (D_{10,\text{mm}})^2 \quad [0.1 \text{ mm} \leq D_{10,\text{mm}} \leq 3.0 \text{ mm}] \qquad 21.9$$

Table 21.1 *Typical Permeabilities*

material	k (darcys)	K (gal/day-ft^2)
gravel	10^3–10^5	10^4–10^6
gravel/sand	10^3	10^4
clean sand	10^2	10^3
sandstone	10	10^2
dense shale or limestone	10^{-1}	1.0
granite or quartzite	10^{-3}	10^{-2}
clay	10^{-3}	10^{-2}

(Multiply gal/day-ft^2 by 0.1337 to obtain ft^3/day-ft^2.)
(Multiply cm^2 by 0.987×10^{-8} to obtain darcys.)

[3]Permeability can be determined from constant-head permeability tests (sands), falling-head permeability tests (fine sands and silts), consolidation tests (clays), and field tests of wells (in situ gravels and sands).

4. DARCY'S LAW

Movement of groundwater through an aquifer is given by *Darcy's law*, Eq. 21.10.[4] The hydraulic gradient may be specified in either ft/ft (m/m) or ft/mi (m/km), depending on the units of area used.

$$Q = -KiA_{\text{gross}} = -\text{v}_e A_{\text{gross}} \qquad 21.10$$

The *specific discharge* is the same as the *effective velocity*, v_e.

$$q = \frac{Q}{A_{\text{gross}}} = Ki = \text{v}_e \qquad 21.11$$

Darcy's law is applicable only when the Reynolds number is less than 1. Significant deviations have been noted when the Reynolds number is even as high as 2. In Eq. 21.12, D_{mean} is the mean grain diameter.

$$\text{Re} = \frac{\rho q D_{\text{mean}}}{\mu} = \frac{q D_{\text{mean}}}{\nu} \qquad 21.12$$

5. TRANSMISSIVITY

Transmissivity (also known as the *coefficient of transmissivity*) is an index for the rate of groundwater movement. The transmissivity of flow from a saturated aquifer of thickness Y and width b is given by Eq. 21.13. The thickness, Y, of a confined aquifer is the difference in elevations of the bottom and top of the saturated formation. For permeable soil, the thickness, Y, is the difference in elevations of the impermeable bottom and the water table.

$$T = KY \qquad 21.13$$

Combining Eqs. 21.10 and 21.13 gives

$$Q = bTi \qquad 21.14$$

6. SPECIFIC YIELD, RETENTION, AND CAPACITY

The dimensionless *storage constant (storage coefficient)*, S, of a confined aquifer is the change in aquifer water volume per unit surface area of the aquifer per unit change in head. That is, the storage constant is the amount of water that is removed from a column of the aquifer 1 ft^2 (1 m^2) in plan area when the water table drops 1 ft (1 m). For unconfined aquifers, the storage coefficient is virtually the same as the specific yield. Various methods have been proposed for calculating the storage coefficient directly from properties of the rock and water. It can also be determined from unsteady flow analysis of wells. (See Sec. 12.)

[4]The negative sign in Darcy's law accounts for the fact that flow is in the direction of decreasing head. That is, the hydraulic gradient is negative in the direction of flow. The negative sign is omitted in the remainder of this chapter, or appropriate equations are rearranged to be positive.

The *specific yield*, S_y, is the water yielded when water-bearing material drains by gravity. It is the volume of water removed per unit area when a drawdown of one length unit is experienced. A time period may be given for different values of specific yield.

$$S_y = \frac{V_{\text{yielded}}}{V_{\text{total}}} \qquad 21.15$$

The *specific retention* is the volume of water that, after being saturated, will remain in the aquifer against the pull of gravity.

$$S_r = \frac{V_{\text{retained}}}{V_{\text{total}}} = n - S_y \qquad 21.16$$

The *specific capacity* of an aquifer is the discharge rate divided by the drawdown.

$$\text{specific capacity} = \frac{Q}{s} \qquad 21.17$$

7. DISCHARGE VELOCITY AND SEEPAGE VELOCITY

The *pore velocity* is given by Eq. 21.18.[5]

$$\text{v}_{\text{pore}} = \frac{Q}{A_{\text{net}}} = \frac{Q}{nA_{\text{gross}}} = \frac{Q}{nbY} = \frac{Ki}{n} \qquad 21.18$$

The gross cross-sectional area in flow depends on the aquifer dimensions. However, water can only flow through voids (pores) in the aquifer. If the gross cross-sectional area is known, it will be necessary to multiply by the porosity to reduce the area in flow. (The hydraulic conductivity is not affected.)

The *seepage velocity* (also known as the *apparent velocity* or the *equivalent velocity*) through a porous medium is the velocity of flow averaged over the gross aquifer cross-sectional area.

$$\text{v}_e = n\text{v}_{\text{pore}} = \frac{Q}{A_{\text{gross}}} = \frac{Q}{bY} = Ki \qquad 21.19$$

Contaminants introduced into an acquifer will migrate from place to place at the seepage velocity given by Eq. 21.19. The pore velocity (Eq. 21.18) should not be used to determine the overland time taken and distance moved by a contaminant.

8. FLOW DIRECTION

Flow direction will be from an area with a high piezometric head (as determined from observation wells) to an area of low piezometric head. Piezometric head is assumed to vary linearly between points of known head.

[5]The pore velocity is also known as the *unit velocity, average velocity*, and the *Darcy velocity*. However, these terms are ambiguous and are not frequently used.

Similarly, all points along a line joining two points with the same piezometric head can be considered to have the same head.

9. WELLS

Water in aquifers can be extracted from *gravity wells.* However, *monitor wells* may also be used to monitor the quality and quantity of water in an aquifer. *Relief wells* are used to dewater soil.

Wells may be dug, bored, driven, jetted, or drilled in a number of ways, depending on the aquifer material and the depth of the well. Wells deeper than 100 ft (30 m) are usually drilled. After construction, the well is *developed*, which includes the operations of removing any fine sand and mud. Production is *stimulated* by increasing the production rate. The fractures in the rock surrounding the well are increased in size by injecting high-pressure water or using similar operations.

Well equipment is *sterilized* by use of chlorine or other disinfectants. The strength of any chlorine solution used to disinfect well equipment should not be less than 100 ppm by weight (i.e., 100 kg of chlorine per 10^6 kg of water). Calcium hypochlorite (which contains 65% available chlorine) and sodium hypochlorite (which contains 12.5% available chlorine) are commonly used for this purpose. The mass of any chlorine-supplying compound with fractional availability A required to produce V gallons of disinfectant with concentration C is

$$m_{\text{lbm}} = (8.33 \times 10^{-6}) V_{\text{gal}} \left(\frac{C_{\text{ppm}}}{A_{\text{decimal}}} \right) \qquad 21.20$$

Figure 21.1 illustrates a typical water-supply well. Water is removed from the well through the *riser pipe* (*eductor pipe*). Water enters the well though a perforated or slotted casing known as the *screen.* The required *open area* depends on the flow rate and is limited by the maximum permissible entrance velocity that will not lift grains larger than a certain size. Table 21.2 recommends maximum flow velocities as functions of the grain diameter. A safety factor of 1.5 to 2.0 is also used to account for the fact that parts of the screen may become blocked. As a general rule, the openings should also be smaller than D_{50} (i.e., smaller than 50% of the screen material particles).

Table 21.2 *Lifting Velocity of Water*[a]

grain diameter (mm)	maximum water velocity (ft/sec)	(m/s)
0 to 0.25	0.10	0.030
0.25 to 0.50	0.22	0.066
0.50 to 1.00	0.33	0.10
1.00 to 2.00	0.56	0.17
2.00 to 4.00	2.60	0.78

(Multiply ft/sec by 0.3 to obtain m/s.)
[a]Spherical particles with specific gravity of 2.6.

Screens do not necessarily extend the entire length of the well. The required screen length can be determined from the total amount of open area required and the open area per unit length of casing. For confined aquifers, screens are usually installed in the middle 70 to 80% of the well. For unconfined aquifers, screens are usually installed in the lower 30 to 40% of the well.

It is desirable to use screen openings as large as possible to reduce entrance friction losses. Larger openings can be tolerated if the well is surrounded by a *gravel pack* to prevent fine material from entering the well. Gravel packs are generally required in soils where the D_{90} size (i.e., the sieve size retaining 90% of the soil) is less than 0.01 in (0.25 mm) and when the well goes through layers of sand and clay.

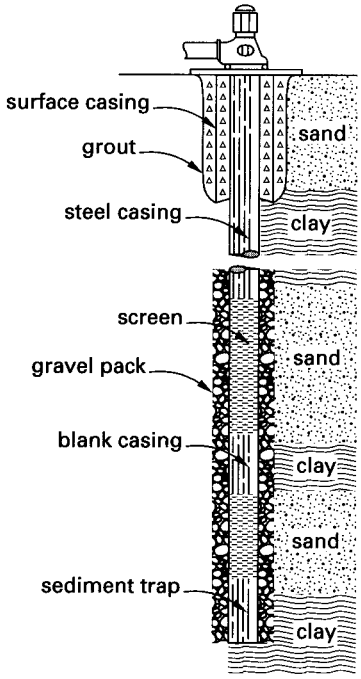

Figure 21.1 *Typical Gravity Well*

10. DESIGN OF GRAVEL SCREENS AND POROUS FILTERS

Gravel and other porous materials may be used as filters as long as their voids are smaller than the particles to be excluded. Actually, only the largest 15% of the particles need to be filtered out, since the agglomeration of these particles will themselves create even smaller openings, and so on.

In specifying the opening sizes for screens, perforated pipe, and fabric filters, the following criteria are in widespread use as the basis for filter design.

$$D_{\text{opening,filter}} \leq D_{85,\text{soil}} \qquad 21.21$$

$$D_{15,\text{filter}} \leq 5D_{85,\text{soil}} \qquad 21.22$$

$$D_{15,\text{filter}} \leq 5D_{15,\text{soil}} \qquad 21.23$$

As stated in Sec. 9, the screen openings should also be smaller than D_{50} (i.e., smaller than 50% of the screen material particles).

The *coefficient of uniformity*, C_u, is used to determine whether the filter particles are properly graded. Only uniform materials ($C_u < 2.5$) and well-graded materials ($2.5 < C < 6$) are suitable for use as filters.

$$C_u = \frac{D_{60}}{D_{10}} \qquad 21.24$$

11. WELL DRAWDOWN IN AQUIFERS

An aquifer with a well is shown in Fig. 21.2. Once pumping begins, the water table will be lowered in the vicinity of the well. The resulting water table surface is referred to as a *cone of depression*. The decrease in water level at some distance r from the well is known as the *drawdown*, s_r. The drawdown at the well is denoted as s_o.

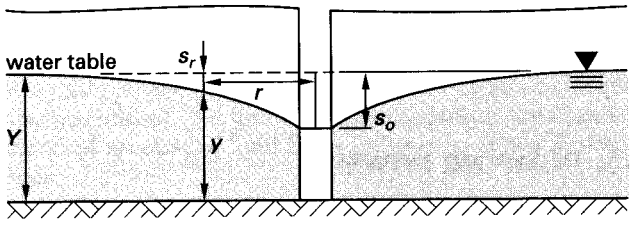

Figure 21.2 *Well Drawdown in an Unconfined Aquifer*

If the drawdown is small with respect to the aquifer thickness, Y, and the well completely penetrates the aquifer, the equilibrium (steady-state) well discharge is given by the *Dupuit equation*, Eq. 21.25. Equation 21.25 can only be used to determine the equilibrium flow rate a "long time" after pumping has begun.

$$Q = \frac{\pi K(y_1^2 - y_2^2)}{\ln\left(\frac{r_1}{r_2}\right)} \qquad 21.25$$

In Eq. 21.25, y_1 and y_2 are the aquifer depths at radial distances r_1 and r_2, respectively, from the well. y_1 can also be taken as the original aquifer depth, Y, if r_1 is the well's *radius of influence*, the distance at which the well has no effect on the water table level.

In very thick unconfined aquifers where the drawdown is negligible compared to the aquifer thickness, or in confined aquifers where there is no cone of depression at all, $y_1 + y_2$ is essentially equal to $2Y$. Then, since $y_2 - y_1 = s_1 - s_2$, $y_2^2 - y_1^2 = (y_2 - y_1)(y_2 + y_1) = 2Y(s_1 - s_2)$. Using this equality and Eq. 21.13, Eq. 21.25 can be written as

$$Q = \frac{2\pi T(s_2 - s_1)}{\ln\left(\frac{r_1}{r_2}\right)} \qquad 21.26$$

For an artesian well fed by a confined aquifer of thickness Y, the discharge is given by the *Thiem equation.*

$$Q = \frac{2\pi KY(y_1 - y_2)}{\ln\left(\frac{r_1}{r_2}\right)} \qquad 21.27$$

The rate (or amount in some period) of water that can be extracted without experiencing some undesirable result is known as the *safe yield.* Undesirable results include deteriorations in the water quality, large pump lifts, and infringement on the water rights of others. Extractions in excess of the safe yield are known as *overdrafts.*

Example 21.1

A 9 in (25 cm) diameter well is pumped at the rate of 50 gal/min (0.2 m^3/min). The aquifer is 100 ft (30 m) thick. After some time, the well sides cave in and are replaced with an 8 in (20 cm) diameter tube. The drawdown is 6 ft (2 m). The water table recovers its original thickness 2500 ft (750 m) from the well. What will be the steady flow from the new well?

SI Solution

$$r_2 = \frac{25 \text{ cm}}{2} = 12.5 \text{ cm} \quad (0.125 \text{ m})$$
$$y_2 = 30 \text{ m} - 2 \text{ m} = 28 \text{ m}$$

Rearrange Eq. 21.25 to determine hydraulic conductivity from the given information.

$$K = \frac{Q \ln\left(\frac{r_1}{r_2}\right)}{\pi(y_1^2 - y_2^2)}$$
$$= \frac{\left(0.2 \frac{\text{m}^3}{\text{min}}\right) \ln\left(\frac{750 \text{ m}}{0.125 \text{ m}}\right)}{\pi\left((30 \text{ m})^2 - (28 \text{ m})^2\right)}$$
$$= 0.004774 \text{ m/min} \quad (0.007957 \text{ cm/s})$$

For the relined well,

$$r_2 = \frac{20 \text{ cm}}{2} = 10 \text{ cm} \quad (0.10 \text{ m})$$

Use Eq. 21.25 to solve for the new flow rate.

$$Q = \frac{\pi K(y_1^2 - y_2^2)}{\ln\left(\frac{r_1}{r_2}\right)}$$
$$= \pi\left(0.004774 \frac{\text{m}}{\text{min}}\right)\left(\frac{(30 \text{ m})^2 - (28 \text{ m})^2}{\ln\left(\frac{750 \text{ m}}{0.10 \text{ m}}\right)}\right)$$
$$= 0.195 \text{ m}^3/\text{min}$$

Customary U.S. Solution

$$r_2 = \frac{9 \text{ in}}{(2)\left(12 \frac{\text{in}}{\text{ft}}\right)} = 0.375 \text{ ft}$$

$$y_2 = 100 \text{ ft} - 6 \text{ ft} = 94 \text{ ft}$$

$$Q = \left(50 \frac{\text{gal}}{\text{min}}\right)\left(0.002228 \frac{\text{ft}^3\text{-min}}{\text{sec-gal}}\right)$$
$$= 0.1114 \text{ ft}^3/\text{sec}$$

Rearrange Eq. 21.25 to find the hydraulic conductivity.

$$K = \frac{Q \ln\left(\frac{r_1}{r_2}\right)}{\pi(y_1^2 - y_2^2)}$$
$$= \frac{\left(50 \frac{\text{gal}}{\text{min}}\right)\left(1440 \frac{\text{min}}{\text{day}}\right)\ln\left(\frac{2500 \text{ ft}}{0.375 \text{ ft}}\right)}{\pi\left((100 \text{ ft})^2 - (94 \text{ ft})^2\right)}$$
$$= 173.4 \text{ gal/day-ft}^2$$

For the relined well,

$$r_2 = \frac{8 \text{ in}}{(2)\left(12 \frac{\text{in}}{\text{ft}}\right)} = 0.333 \text{ ft}$$

Use Eq. 21.25 to solve for the new flow rate.

$$Q = \frac{\pi K(y_1^2 - y_2^2)}{\ln\left(\frac{r_1}{r_2}\right)}$$
$$= \frac{\pi\left(173.4 \frac{\text{gal}}{\text{day-ft}^2}\right)\left((100 \text{ ft})^2 - (94 \text{ ft})^2\right)}{\ln\left(\frac{2500 \text{ ft}}{0.333 \text{ ft}}\right)}$$
$$= 71{,}042 \text{ gal/day}$$

12. UNSTEADY FLOW

When pumping first begins, the removed water also comes from the aquifer above the equilibrium cone of depression. Therefore, Eq. 21.26 cannot be used, and a nonequilibrium analysis is required.

Nonequilibrium solutions to well problems have been formulated in terms of dimensionless numbers. For small drawdowns compared with the initial thickness of the aquifer, the *Theis equation* for the drawdown at a distance r from the well and after pumping for time t is

$$s_{r,t} = \left(\frac{Q}{4\pi KY}\right)W(u)$$
$$= \left(\frac{Q}{4\pi T}\right)W(u) \qquad 21.28$$

$W(u)$ is a dimensionless *well function.* Though it is possible to obtain $W(u)$ from u, extracting u from $W(u)$ is more difficult. The relationship between u and $W(u)$ is often given in tabular or graphical forms. In Eq. 21.30, S is the aquifer *storage constant.*

$$W(u) = -0.577216 - \ln u + u - \frac{u^2}{(2)(2!)}$$
$$+ \frac{u^3}{(3)(3!)} - \frac{u^4}{(4)(4!)} + \ldots \qquad 21.29$$

$$u = \frac{r^2 S}{4KYt} = \frac{r^2 S}{4Tt} \qquad 21.30$$

Accordingly, for any two different times in the pumping cycle,

$$s_1 - s_2 = y_2 - y_1 = \left(\frac{Q}{4\pi KY}\right)\left(W(u_1) - W(u_2)\right) \qquad 21.31$$

If $u < 0.01$, then *Jacob's equation* can be used.

$$s_{r,t} = \left(\frac{Q}{4\pi T}\right)\ln\left(\frac{2.25Tt}{r^2 S}\right) \qquad 21.32$$

13. PUMPING POWER

Various types of pumps are used in wells. Problems with excessive suction lift are avoided by the use of submersible pumps.

Pumping power can be determined from the hydraulic (water) power equations presented in Chap. 18. The total head is the sum of static lift, velocity head, drawdown, pipe friction, and minor entrance losses from the casing, strainer, and screen. The Hazen-Williams equation is commonly used with a coefficient of $C = 100$ to determine the pipe friction.

14. FLOW NETS

Groundwater seepage is from locations of high hydraulic head to locations of lower hydraulic head. Relatively complex two-dimensional problems may be evaluated using a graphical technique that shows the decrease in hydraulic head along the flow path. The resulting graphic representation of pressure and flow path is called a *flow net.*

The flow net concept as discussed here is limited to cases where the flow is steady, two-dimensional, incompressible, and through a homogeneous medium, and where the liquid has a constant viscosity. This is the ideal case of groundwater seepage.

Flow nets are constructed from streamlines and equipotential lines. *Streamlines (flow lines)* show the path taken by the seepage. *Equipotential lines* are contour lines of constant hydraulic head.

Table 21.3 *Well Function W(u) for Various Values of u*

u	1.0	2.0	3.0	4.0	5.0	6.0	7.0	8.0	9.0

Reprinted from L. K. Wenzel, "Methods for Determining Permeability of Water Bearing Materials with Special Reference to Discharging Well Methods," U.S. Geological Survey, 1942, Water-Supply Paper 887.

The object of a graphical flow net solution is to construct a network of flow paths (outlined by the streamlines) and equal pressure drops (bordered by equipotential lines). No fluid flows across streamlines, and a constant amount of fluid flows between any two streamlines.

Flow nets are constructed according to the following rules.

Rule 21.1: Streamlines enter and leave pervious surfaces perpendicular to those surfaces.

Rule 21.2: Streamlines approach the line of seepage (above which there is no hydrostatic pressure) asymptotically to that surface.

Rule 21.3: Streamlines are parallel to but cannot touch impervious surfaces that are streamlines.

Rule 21.4: Streamlines are parallel to the flow direction.

Rule 21.5: Equipotential lines are drawn perpendicular to streamlines such that the resulting cells are approximately square and the intersections are 90° angles. Theoretically, it should be possible to draw a perfect circle within each cell that touches all four boundaries, even though the cell is not actually square.

Rule 21.6: Equipotential lines enter and leave impervious surfaces perpendicular to those surfaces.

Many flow nets with differing degrees of detail can be drawn, and all will be more or less correct. Generally, three to five streamlines are sufficient for initial graphical evaluations. The size of the cells is determined by the number of intersecting streamlines and equipotential lines. As long as the rules are followed, the ratio of stream flow channels to equipotential drops will be approximately constant regardless of whether the grid is coarse or fine.

Figure 21.3 shows flow nets for several common cases. A careful study of the flow nets will help to clarify the rules and conventions previously listed.

15. SEEPAGE FROM FLOW NETS

Once a flow net is drawn, it can be used to calculate the seepage. First, the number of flow channels, N_f, between the streamlines is counted. Then, the number of equipotential drops, N_p, between equipotential lines is counted. The total hydraulic head, H, is determined as a function of the water surface levels.

$$Q = KH\left(\frac{N_f}{N_p}\right) \qquad 21.33$$

$$H = H_1 - H_2 \qquad 21.34$$

16. HYDROSTATIC PRESSURE ALONG FLOW PATH

The hydrostatic pressure at equipotential drop j (counting the last line on the downstream side as zero) in a flow net with a total of N_p equipotential drops is given by Eq. 21.35. If the point being investigated is along the bottom of a dam or other structure, the hydrostatic pressure is referred to as *uplift pressure*. Since uplift due to velocity is negligible, all uplift is due to the neutral pore pressure. Therefore, *neutral pressure* is synonymous with uplift pressure.

$$p_u = \left(\frac{j}{N_p}\right) H\gamma_w \qquad 21.35$$

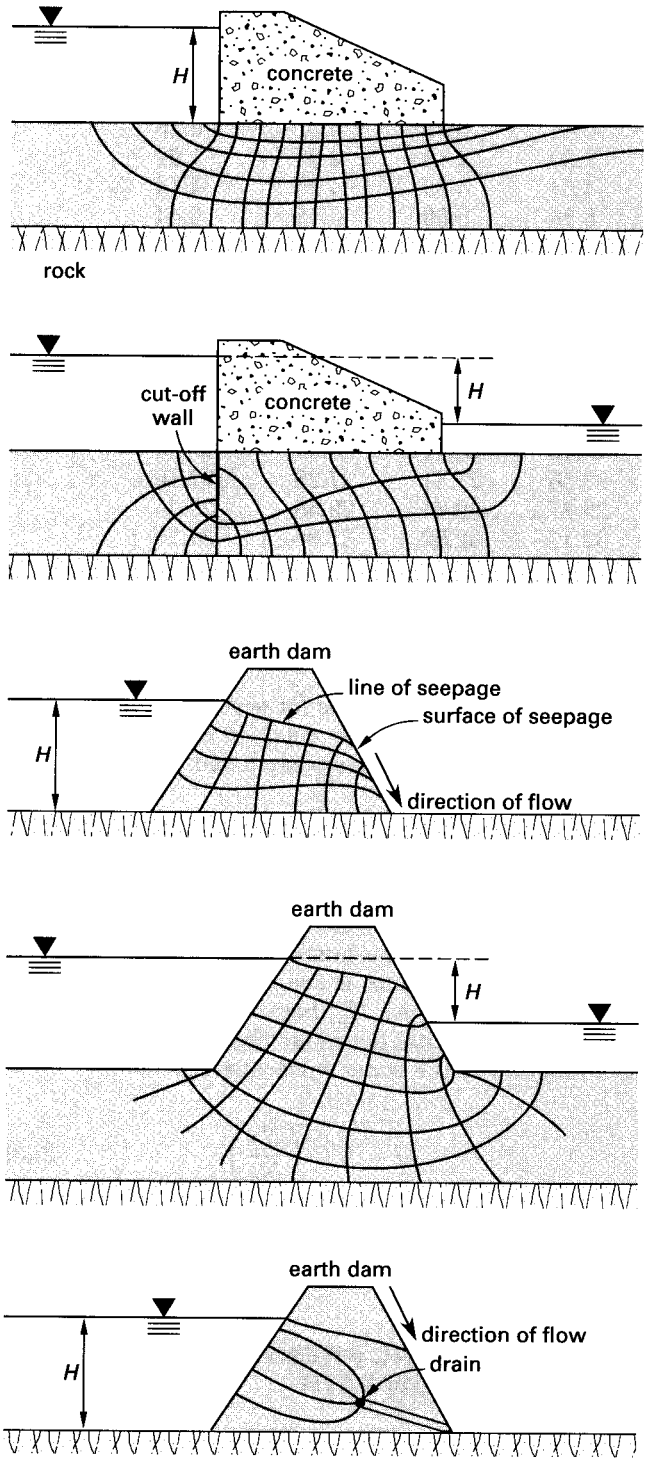

Figure 21.3 *Typical Flow Nets*

If the point being investigated is located a distance z below the datum, then the pressure at the point is given by Eq. 21.36. If the point being investigated is above the datum, z is negative.

$$p_u = \left(\left(\frac{j}{N_p} \right) H + z \right) \gamma_w \qquad 21.36$$

The actual *uplift force* on a surface of area A is given by Eq. 21.37. N is the *neutral stress coefficient*, defined as the fraction of the surface that is exposed to the hydrostatic pressure. For soil, $N \approx 1$. However, for fractured rock, concrete, porous limestone, or sandstone, it varies from 0.5 to 1.0. For impervious materials such as marble or granite, it can be as low as 0.1.

$$U = N p_u A \qquad 21.37$$

As Table 21.1 indicates, some clay layers are impervious enough to prohibit the passing of water. However, the hydrostatic uplift pressure below a clay layer can still be transmitted through the clay layer. The transfer geometry for thick layers is complex, making estimates of the amount of uplift force difficult. Upward forces on an impervious layer due to hydrostatic pressure below is known as *heave*. A factor of safety against heave of at least 1.5 is desirable.

$$(\text{FS})_{\text{heave}} = \frac{\text{downward pressure}}{\text{uplift pressure}} \qquad 21.38$$

17. INFILTRATION

Aquifers can be recharged (refilled) in a number of natural and artificial ways. *Horton's equation* gives the *infiltration* (in inches of rainfall per unit time) of water into an aquifer from a saturated source above as a function of time. In Eq. 21.39, f_c is the final or equilibrium capacity, f_0 is the initial infiltration capacity, and f_t is the infiltration capacity at time t. When the rainfall supply exceeds the infiltration capacity, infiltration decreases exponentially over time. k is an infiltration decay constant with dimensions of time^{-1}.

$$f_t = f_c + (f_0 - f_c)e^{-kt} \qquad 21.39$$

The cumulative infiltration over time t is

$$F_t = f_c t + \frac{f_0 - f_c}{k} \qquad 21.40$$

The cumulative infiltration, F, will not correspond to the eventual increase in water table elevation due to the effects of porosity. However, the increase in water table elevation can be determined from a knowledge of the aquifer properties.

PRACTICE PROBLEMS

Wells

1. A well extends from the ground surface at elevation 383 ft through a gravel bed to a layer of bedrock at elevation 289 ft. The screened well is 1500 ft from a river whose surface level is 363 ft. The well is pumped by a 10 in diameter schedule-40 steel pipe that draws

120,000 gal/day. The hydraulic conductivity of the well is 1600 gal/day-ft^2. The pump discharges into a piping network whose friction head is 100 ft. What net power is required for steady flow?

(A) 1.1 hp
(B) 2.6 hp
(C) 7.8 hp
(D) 15 hp

The answer is (B).

2. (*Time limit: one hour*) An aquifer consists of a homogeneous material 300 ft thick. The surface of the water table in this aquifer is 100 ft below ground surface. An 18 in diameter well extends through the top 100 ft and then 200 ft below the water table, for a total depth of 300 ft. The aquifer transmissivity is 10,000 gal/day-ft. The well's radius of influence is 900 ft with a 20 ft drawdown at the well.

(a) The geologic formation in which the well is installed is called

(A) an aquifuge.
(B) an artesian well.
(C) a connate aquifer.
(D) an unconfined aquifer.

The answer is (D).

(b) What is the hydraulic conductivity of the aquifer?

(A) 50 gal/day-ft^2
(B) 500 gal/day-ft^2
(C) 1300 gal/day-ft^2
(D) 10,000 gal/day-ft^2

The answer is (A).

(c) What steady discharge is possible?

(A) 0.26 ft^3/sec
(B) 0.52 ft^3/sec
(C) 1.2 ft^3/sec
(D) 5.2 ft^3/sec

The answer is (A).

(d) What is the drawdown 100 ft from the well?

(A) 1 ft
(B) 6 ft
(C) 13 ft
(D) 18 ft

The answer is (B).

(e) What horsepower motor should be selected to achieve the steady discharge?

(A) 3.6 hp
(B) 5.5 hp
(C) 7.5 hp
(D) 12.2 hp

The answer is (C).

The same well conditions are found at an adjacent site where the aquifer is overlain by a material of low permeability that is 200 ft thick. The piezometric surface is 100 ft below the ground surface.

(f) The geologic formation in which the well is installed is called

(A) an aquifuge.
(B) a confined aquifer.
(C) a spring.
(D) a vadose well.

The answer is (B).

(g) The 18 in diameter well extends 300 ft below the ground surface to the bottom of the aquifer. The aquifer transmissivity is 10,000 gal/day-ft. What is the hydraulic conductivity of the aquifer?

(A) 50 gal/day-ft^2
(B) 100 gal/day-ft^2
(C) 500 gal/day-ft^2
(D) 800 gal/day-ft^2

The answer is (B).

(h) What is the steady discharge in the well if the radius of influence is 900 ft with a 20 ft drawdown at the well?

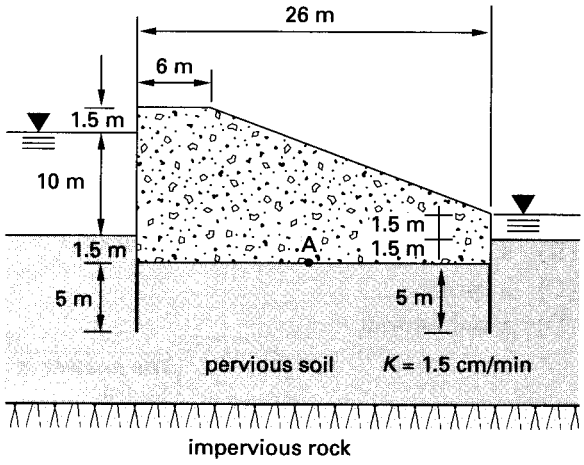
(A) 0.27 ft^3/sec
(B) 0.62 ft^3/sec
(C) 1.2 ft^3/sec
(D) 3.5 ft^3/sec

The answer is (A).

(i) At what distance from the well is the drawdown equal to 10 ft?

(A) 3 ft
(B) 26 ft
(C) 130 ft
(D) 450 ft

The answer is (B).



(j) After pumping is stopped, groundwater flows in one direction through the aquifer. If the aquifer is only 100 ft wide and the porosity is 0.4, what is the area in clear flow?

(A) 2000 ft^2
(B) 4000 ft^2
(C) 8000 ft^2
(D) 20,000 ft^2

The answer is (B).

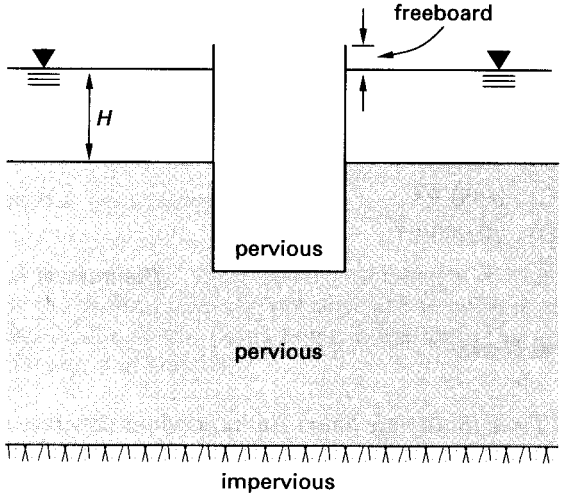
Flow Nets

3. (*Time limit: one hour*) An impervious concrete dam is shown. The dam reduces seepage by using two impervious sheets extending 5 m below the dam bottom.

(a) Sketch the flow net.

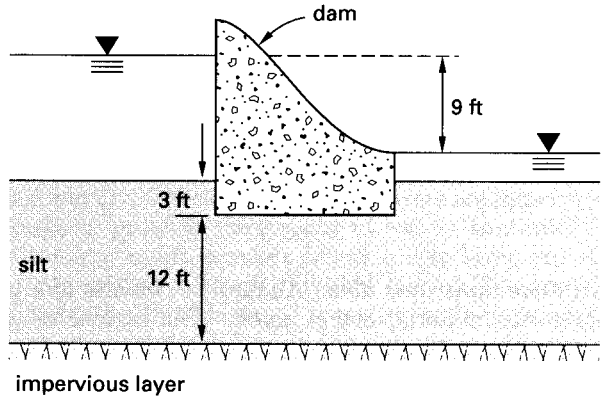
(b) Determine the seepage per meter of width.

(A) 0.03 m^3/min
(B) 0.1 m^3/min
(C) 0.3 m^3/min
(D) 0.9 m^3/min



The answer is (A).

(c) What is the uplift pressure on the dam at point A, midway between the left and right edges?



(A) 17 kPa
(B) 33 kPa
(C) 56 kPa
(D) 91 kPa

The answer is (C).

4. (*Time limit: one hour*) A cofferdam in a river is shown. Sheet piles extend below the mud line, and the cofferdam floor is unlined. (The figure is drawn to scale.) Draw the flow net.

5. (*Time limit: one hour*) The concrete dam shown is drawn to scale. The silt has a hydraulic conductivity of 0.15 ft/hr.

(a) Sketch the flow net for the dam.

(b) What is the approximate seepage rate per foot of width?

(A) 0.05 ft^3/hr-ft width
(B) 0.20 ft^3/hr-ft width
(C) 0.40 ft^3/hr-ft width
(D) 0.90 ft^3/hr-ft width

The answer is (C).

1. ATOMIC STRUCTURE

An *element* is a substance that cannot be decomposed into simpler substances during ordinary chemical reactions.[1] An *atom* is the smallest subdivision of an element that can take part in a chemical reaction. A *molecule* is the smallest subdivision of an element or compound that can exist in a natural state.

The atomic nucleus consists of neutrons and protons, known as *nucleons*. The masses of neutrons and protons are essentially the same—one *atomic mass unit*, amu. (One amu is exactly $^1/_{12}$ of the mass of an atom of carbon-12, approximately equal to 1.66×10^{-27} kg.[2]) The *relative atomic weight* or *atomic weight*, A, of an atom is approximately equal to the number of protons

[1] Atoms of an element can be decomposed into subatomic particles in nuclear reactions.

[2] Until 1961, the atomic mass unit was defined as $^1/_{16}$ of the mass of one atom of oxygen-16. The carbon-12 reference has now been universally adopted.

and neutrons in the nucleus.[3] The *atomic number*, Z, of an atom is equal to the number of protons in the nucleus.

The atomic number and atomic weight of an element E are written in symbolic form as ${}_{Z}\mathrm{E}^{A}$, E_{Z}^{A}, or ${}_{Z}^{A}\mathrm{E}$. For example, carbon is the sixth element; radioactive carbon has an atomic mass of 14. Therefore, the symbol for carbon-14 is C_{6}^{14}. Since the atomic number is superfluous if the chemical symbol is given, the atomic number can be omitted (e.g., C^{14}).

2. ISOTOPES

Although an element can have only a single atomic number, atoms of that element can have different atomic weights. Many elements possess *isotopes*. The nuclei of isotopes differ from one another only in the number of neutrons. Isotopes behave the same way chemically.[4] Therefore, isotope separation must be done physically (e.g., by centrifugation or gaseous diffusion) rather than chemically.

Hydrogen has three isotopes. H_{1}^{1} is *normal hydrogen* with a single proton nucleus. H_{1}^{2} is known as *deuterium* (*heavy hydrogen*), with a nucleus of a proton and neutron. (This nucleus is known as a *deuteron*.) Finally, H_{1}^{3} (*tritium*) has two neutrons in the nucleus. While normal hydrogen and deuterium are stable, tritium is radioactive. Many elements have more than one stable isotope. Tin, for example, has ten.

The *relative abundance*, x_i, of an isotope i is equal to the fraction of that isotope in a naturally occurring sample of the element. The *chemical atomic weight* is the weighted average of the isotope weights.

$$A_{\text{average}} = x_1 A_1 + x_2 A_2 + \cdots \qquad 22.1$$

3. PERIODIC TABLE

The *periodic table* (App. 22.B) is organized around the *periodic law:* The properties of the elements depend on the atomic structure and vary with the atomic number in a systematic way. Elements are arranged in order of increasing atomic numbers from left to right. Adjacent elements in horizontal rows differ decidedly in both physical and chemical properties. However, elements in the same column have similar properties. Graduations in properties, both physical and chemical, are most pronounced in the *periods* (i.e., the horizontal rows).

The vertical columns are known as *groups*, numbered in Roman numerals. Elements in a group are called *cogeners*. Each vertical group except 0 and VIII has A and B subgroups (*families*). The elements of a family resemble each other more than they resemble elements in the other family of the same group. Graduations in properties are definite but less pronounced in vertical families. The trend in any family is toward more *metallic properties* as the atomic weight increases.

Metals (elements at the left end of the periodic chart) have low electron affinities, are reducing agents, form positive ions, and have positive oxidation numbers. They have high electrical conductivities, luster, generally high melting points, ductility, and malleability.

Nonmetals (elements at the right end of the periodic chart) have high electron affinities, are oxidizing agents, form negative ions, and have negative oxidation numbers. *Nonmetals* are poor electrical conductors, have little or no luster, and form brittle solids.

The *metalloids* (e.g., boron, silicon, germanium, arsenic, antimony, tellurium, and polonium) have characteristics of both metals and nonmetals. Electrically, they are semiconductors.

Elements in the periodic table are often categorized into the following groups.

- *actinides:* same as actinons
- *actinons:* elements 90 to 103[5]
- *alkali metals:* group IA
- *alkaline earth metals:* group IIA
- *halogens:* group VIIA
- *heavy metals:* metals near the center of the chart
- *inner transition elements:* same as transition metals
- *lanthanides:* same as lanthanons
- *lanthanons:* elements 58 to 71[6]
- *light metals:* elements in the first two groups
- *metals:* everything except the nonmetals
- *metalloids:* elements along the dark line in the chart separating metals and nonmetals
- *noble gases:* group 0
- *nonmetals:* elements 2, 5 to 10, 14 to 18, 33 to 36, 52 to 54, 85, and 86
- *rare earths:* same as lanthanons
- *transition elements:* same as transition metals
- *transition metals:* all B families and group VIII[7]

[3]The term *weight* is used even though all chemical calculations involve mass. The atomic weight of an atom includes the mass of the electrons. Published *chemical atomic weights* of elements are averages of all the atomic weights of stable isotopes, taking into consideration the relative abundances of the isotopes.

[4]There are slight differences, known as *isotope effects*, in the chemical behavior of isotopes. These effects usually influence only the rate of reaction, not the kind of reaction.

[5]The *actinons* resemble element 89, *actinium*. Therefore, element 89 is sometimes included as an actinon.

[6]The *lanthanons* resemble element 57, *lanthanum*. Therefore element 57 is sometimes included as a lanthanon.

[7]The *transition metals* are elements whose electrons occupy the d sublevel. They can have various oxidation numbers, including +2, +3, +4, +6, and +7.

4. OXIDATION NUMBER

The *oxidation number* (*oxidation state*) is an electrical charge assigned by a set of prescribed rules. It is actually the charge assuming all bonding is ionic. The sum of the oxidation numbers equals the net charge. For monoatomic ions, the oxidation number is equal to the charge. The oxidation numbers of some common ions and radicals are given in Table 22.1.

For atoms in a free-state molecule, the oxidation number is zero. Hydrogen gas is a diatomic molecule, H_2. Thus, the oxidation number of the hydrogen molecule, H_2, is zero. The same is true for the atoms in O_2, N_2, Cl_2, and so on. Also, the sum of all the oxidation numbers of atoms in a neutral molecule is zero.

For a charged *radical* (a group of atoms that combine as a single unit), the net oxidation number is equal to the charge on the radical.

5. COMPOUNDS

Combinations of elements are known as *compounds. Binary compounds* contain two elements; *ternary* (*tertiary*) *compounds* contain three elements. A *chemical formula* is a representation of the relative numbers of each element in the compound. For example, the formula $CaCl_2$ shows that there are one calcium atom and two chlorine atoms in one molecule of calcium chloride.

Generally, the numbers of atoms are reduced to their lowest terms. However, there are exceptions. For example, acetylene is C_2H_2, and hydrogen peroxide is H_2O_2.

6. FORMATION OF COMPOUNDS

Compounds form according to the *law of definite (constant) proportions:* A pure compound is always composed of the same elements combined in a definite proportion by mass. For example, common table salt is always NaCl. It is not sometimes NaCl and other times Na_2Cl or $NaCl_3$ (which do not exist, in any case).

Furthermore, compounds form according to the *law of (simple) multiple proportions:* When two elements combine to form more than one compound, the masses of one element that combine with the same mass of the other are in the ratios of small integers.

In order to evaluate whether a compound formula is valid, it is necessary to know the *oxidation numbers* of the interacting atoms. Although some atoms have more than one possible oxidation number, most do not.

Table 22.1 *Oxidation Numbers of Selected Atoms and Charge Numbers of Radicals*

name	symbol	oxidation or charge number
acetate	$C_2H_3O_2$	−1
aluminum	Al	+3
ammonium	NH_4	+1
barium	Ba	+2
borate	BO_3	−3
boron	B	+3
bromine	Br	−1
calcium	Ca	+2
carbon	C	+4, −4
carbonate	CO_3	−2
chlorate	ClO_3	−1
chlorine	Cl	−1
chlorite	ClO_2	−1
chromate	CrO_4	−2
chromium	Cr	+2, +3, +6
copper	Cu	+1, +2
cyanide	CN	−1
dichromate	Cr_2O_7	−2
fluorine	F	−1
gold	Au	+1, +3
hydrogen	H	+1
hydroxide	OH	−1
hypochlorite	ClO	−1
iron	Fe	+2, +3
lead	Pb	+2, +4
lithium	Li	+1
magnesium	Mg	+2
mercury	Hg	+1, +2
nickel	Ni	+2, +3
nitrate	NO_3	−1
nitrite	NO_2	−1
nitrogen	N	−3, +1, +2, +3, +4, +5
oxygen	O	−2
perchlorate	ClO_4	−1
permanganate	MnO_4	−1
phosphate	PO_4	−3
phosphorus	P	−3, +3, +5
potassium	K	+1
silicon	Si	+4, −4
silver	Ag	+1
sodium	Na	+1
sulfate	SO_4	−2
sulfite	SO_3	−2
sulfur	S	−2, +4, +6
tin	Sn	+2, +4
zinc	Zn	+2

The sum of the oxidation numbers must be zero if a neutral compound is to form. For example, H_2O is a valid compound since the two hydrogen atoms have a total positive oxidation number of $2 \times 1 = +2$. The oxygen ion has an oxidation number of -2. These oxidation numbers sum to zero.

On the other hand, $NaCO_3$ is not a valid compound formula. The sodium (Na) ion has an oxidation number of $+1$. However, the carbonate radical has a *charge number* of -2. The correct sodium carbonate molecule is Na_2CO_3.

7. MOLES

The *mole* is a measure of the quantity of an element or compound. Specifically, a mole of an element will have a mass equal to the element's atomic (or molecular) weight. The three main types of moles are based on mass being measured in grams, kilograms, and pounds.[8] Obviously, a gram-based mole of carbon (12.0 grams) is not the same quantity as a pound-based mole of carbon (12.0 pounds). Although "mol" is understood in SI countries to mean a gram-mole, the term *mole* is ambiguous, and the units mol (gmol), kmol (kgmol), or lbmol must be specified, or the type of mole must be spelled out.[9]

One gram-mole of any substance has a number of particles (atoms, molecules, ions, electrons, etc.) equal to 6.022×10^{23}, *Avogadro's number*, N_A. A pound-mole contains approximately 454 times the number of particles in a gram-mole.

Avogadro's law (hypothesis) holds that equal volumes of all gases at the same temperature and pressure contain equal numbers of gas molecules. Specifically, at standard scientific conditions (1.0 atm and 0°C), one gram-mole of any gas contains 6.022×10^{23} molecules and occupies 22.4 L. Of course, a pound-mole occupies 454 times that volume (359 ft^3).

"Molar" is used as an adjective when describing properties of a mole. For example, a *molar volume* is the volume of a mole.

Example 22.1

How many moles are in 0.01 g of gold ($A = 196.97$; $Z = 79$)?

Solution

The number of gram-moles of gold present is

$$n = \frac{m}{A} = \frac{0.01 \text{ g}}{196.97 \frac{\text{g}}{\text{mol}}} = 5.077 \times 10^{-5} \text{ mol}$$

[8]Theoretically, a slug-mole could be defined, but it is not used.
[9]There are also variations on the presentation of these units, such as g mol, gmole, g-mole, kmole, kg-mol, lb-mole, pound-mole, and p-mole. In most cases, the intent is clear.

8. FORMULA AND MOLECULAR WEIGHTS

The *formula weight*, FW, of a molecule (compound) is the sum of the atomic weights of all elements in the molecule. The *molecular weight*, MW, is generally the same as the formula weight. The units of molecular weight are actually g/mol, kg/kmol, or lb/lbmol. However, units are sometimes omitted because weights are relative. For example,

$$CaCO_3\text{: FW} = \text{MW} = 40.1 + 12 + 3 \times 16 = 100.1$$

An *ultimate analysis* (which determines how much of each element is present in a compound) will not determine the molecular formula. It will determine only the relative proportions of each element. Therefore, except for hydrated molecules and other linked structures, the molecular weight will be an integer multiple of the formula weight.

For example, an ultimate analysis of hydrogen peroxide (H_2O_2) will show that the compound has one oxygen atom for each hydrogen atom. In this case, the formula would be assumed to be HO and the formula weight would be approximately 17, although the actual molecular weight is 34.

For *hydrated molecules* (e.g., $FeSO_4 \cdot 7H_2O$), the mass of the *water of hydration* (also known as the *water of crystallization*) is included in the formula and in the molecular weight.

9. EQUIVALENT WEIGHT

The *equivalent weight* (i.e., an *equivalent*) is the amount of substance (in grams) that supplies one gram-mole (i.e., 6.022×10^{23}) of reacting units. For acid-base reactions an acid equivalent supplies one gram-mole of H^+ ions. A base equivalent supplies one gram-mole of OH^- ions. In oxidation-reduction reactions, an equivalent of a substance gains or loses a gram-mole of electrons. Similarly, in electrolysis reactions an equivalent weight is the weight of substance that either receives or donates one gram-mole of electrons at an electrode.

The equivalent weight can be calculated as the molecular weight divided by the change in oxidation number experienced in a chemical reaction. A substance can have several equivalent weights.

$$\text{EW} = \frac{\text{MW}}{\Delta \text{ oxidation number}} \qquad 22.2$$

Example 22.2

What are the equivalent weights of the following compounds?

(a) Al in the reaction

$$Al^{+++} + 3e^- \longrightarrow Al$$

(b) H_2SO_4 in the reaction

$$H_2SO_4 + H_2O \longrightarrow 2H^+ + SO_4^{--} + H_2O$$

(c) NaOH in the reaction

$$NaOH + H_2O \longrightarrow Na^+ + OH^- + H_2O$$

Solution

(a) The atomic weight of aluminum is approximately 27. Since the change in the oxidation number is 3, the equivalent weight is $27/3 = 9$.

(b) The molecular weight of sulfuric acid is approximately 98. Since the acid changes from a neutral molecule to ions with two charges each, the equivalent weight is $98/2 = 49$.

(c) Sodium hydroxide has a molecular weight of approximately 40. The originally neutral molecule goes to a singly charged state. Therefore, the equivalent weight is $40/1 = 40$.

10. GRAVIMETRIC FRACTION

The *gravimetric fraction*, x_i, of an element i in a compound is the fraction by weight of that element in the compound. The gravimetric fraction is found from an *ultimate analysis* (also known as a *gravimetric analysis*) of the compound.

$$x_i = \frac{m_i}{m_1 + m_2 + \cdots + m_i + \cdots + m_n} = \frac{m_i}{m_t} \qquad 22.3$$

The *percentage composition* is the gravimetric fraction converted to percentage.

$$\%\ \text{composition} = x_i \times 100\% \qquad 22.4$$

If the gravimetric fractions are known for all elements in a compound, the *combining weights* of each element can be calculated. (The term *weight* is used even though mass is the traditional unit of measurement.)

$$m_i = x_i m_t \qquad 22.5$$

11. EMPIRICAL FORMULA DEVELOPMENT

It is relatively simple to determine the *empirical formula* of a compound from the atomic and combining weights of elements in the compound. The empirical formula gives the relative number of atoms (i.e., the formula weight is calculated from the empirical formula).

step 1: Divide the gravimetric fractions (or percentage compositions) by the atomic weight of each respective element.

step 2: Determine the smallest ratio from step 1.

step 3: Divide all of the ratios from step 1 by the smallest ratio.

step 4: Write the chemical formula using the results from step 3 as the numbers of atoms. Multiply through as required to obtain all integer numbers of atoms.

Example 22.3

A clear liquid is analyzed, and the following percentage compositions are recorded: carbon, 37.5%; hydrogen, 12.5%; oxygen, 50%. What is the chemical formula for the liquid?

Solution

step 1: Divide the percentage compositions by the atomic weight.

$$\text{C:}\quad \frac{37.5}{12} = 3.125$$

$$\text{H:}\quad \frac{12.5}{1} = 12.5$$

$$\text{O:}\quad \frac{50}{16} = 3.125$$

steps 2 and 3: The smallest ratio is 3.125. Divide all ratios by 3.125.

$$\text{C:}\quad \frac{3.125}{3.125} = 1$$

$$\text{H:}\quad \frac{12.5}{3.125} = 4$$

$$\text{O:}\quad \frac{3.125}{3.125} = 1$$

step 4: The empirical formula is CH_4O.

If it had been known that the liquid behaved chemically as though it had a hydroxyl (OH) radical, the formula would have been written as CH_3OH. This is recognized as methyl alcohol.

12. CHEMICAL REACTIONS

During chemical reactions, bonds between atoms are broken and new bonds are usually formed. The starting substances are known as *reactants*; the ending substances are known as *products*. In a chemical reaction, reactants are either converted to simpler products or synthesized into more complex compounds. There are four common types of reactions.

- *direct combination (or synthesis):* This is the simplest type of reaction where two elements or compounds combine directly to form a compound.

$$2H_2 + O_2 \longrightarrow 2H_2O$$

$$SO_2 + H_2O \longrightarrow H_2SO_3$$

- *decomposition (*or *analysis):* Bonds within a compound are disrupted by heat or other energy to produce simpler compounds or elements.

$$2HgO \longrightarrow 2Hg + O_2$$
$$H_2CO_3 \longrightarrow H_2O + CO_2$$

- *single displacement (*or *replacement):* This type of reaction has one element and one compound as reactants.

$$2Na + 2H_2O \longrightarrow 2NaOH + H_2$$
$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

- *double displacement (*or *replacement*[10]*):* These are reactions with two compounds as reactants and two compounds as products.

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$
$$H_2SO_4 + ZnS \longrightarrow H_2S + ZnSO_4$$

13. BALANCING CHEMICAL EQUATIONS

The coefficients in front of element and compound symbols in chemical reaction equations are the numbers of molecules or moles taking part in the reaction. (For gaseous reactants and products, the coefficients also represent the numbers of volumes. This is a direct result of Avogadro's hypothesis that equal numbers of molecules in the gas phase occupy equal volumes under the same conditions.)[11]

Since atoms cannot be changed in a normal chemical reaction (i.e., mass is conserved), the numbers of each element must match on both sides of the equation. When the numbers of each element match, the equation is said to be "balanced." The total atomic weights on both sides of the equation will be equal when the equation is balanced.

Balancing simple chemical equations is largely a matter of deductive trial and error. More complex reactions require use of oxidation numbers.

Example 22.4

Balance the following reaction equation.

$$Al + H_2SO_4 \longrightarrow Al_2(SO_4)_3 + H_2$$

Solution

As written, the reaction is not balanced. For example, there is one aluminum on the left, but there are two on the right. The starting element in the balancing procedure is chosen somewhat arbitrarily.

step 1: Since there are two aluminums on the right, multiply Al by 2.

$$2Al + H_2SO_4 \longrightarrow Al_2(SO_4)_3 + H_2$$

step 2: Since there are three sulfate radicals (SO_4) on the right, multiply H_2SO_4 by 3.

$$2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + H_2$$

step 3: Now there are six hydrogens on the left, so multiply H_2 by 3 to balance the equation.

$$2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 3H_2$$

14. STOICHIOMETRIC REACTIONS

Stoichiometry is the study of the proportions in which elements and compounds react and are formed. A *stoichiometric reaction* (also known as a *perfect reaction* or an *ideal reaction*) is one in which just the right amounts of reactants are present. After the reaction stops, there are no unused reactants.

Stoichiometric problems are known as *weight and proportion problems* because their solutions use simple ratios to determine the masses of reactants required to produce given masses of products, or vice versa. The procedure for solving these problems is essentially the same regardless of the reaction.

step 1: Write and balance the chemical equation.

step 2: Determine the atomic (molecular) weight of each element (compound) in the equation.

step 3: Multiply the atomic (molecular) weights by their respective coefficients and write the products under the formulas.

step 4: Write the given mass data under the weights determined in step 3.

step 5: Fill in the missing information by calculating simple ratios.

Example 22.5

Caustic soda (NaOH) is made from sodium carbonate (Na_2CO_3) and slaked lime ($Ca(OH)_2$) according to the given reaction. How many kilograms of caustic soda can be made from 2000 kg of sodium carbonate?

Solution

	Na_2CO_3	+ $Ca(OH)_2$	$\longrightarrow$ $2NaOH$	+ $CaCO_3$
molecular weights	106	74	2×40	100
given data	2000 kg		X kg	

[10] Another name for replacement is *metathesis.*

[11] When water is part of the reaction, the interpretation that the coefficients are volumes is valid only if the reaction takes place at a high enough temperature to vaporize the water.

The simple ratio used is

$$\frac{\text{NaOH}}{\text{Na}_2\text{CO}_3} = \frac{80}{106} = \frac{X}{2000}$$

Solving for the unknown mass, $X = 1509$ kg.

15. NONSTOICHIOMETRIC REACTIONS

In many cases, it is not realistic to assume a stoichiometric reaction because an excess of one or more reactants is necessary to assure that all of the remaining reactants take part in the reaction. Combustion is an example where the stoichiometric assumption is, more often than not, invalid. Excess air is generally needed to ensure that all of the fuel is burned.

With nonstoichiometric reactions, the reactant that is used up first is called the *limiting reactant.* The amount of product will be dependent on (limited by) the limiting reactant.

The *theoretical yield* or *ideal yield* of a product is the maximum amount of product per unit amount of limiting reactant that can be obtained from a given reaction if the reaction goes to completion. The *percentage yield* is a measure of the efficiency of the actual reaction.

$$\text{percentage yield} = \frac{\text{actual yield} \times 100\%}{\text{theoretical yield}} \qquad 22.6$$

16. SOLUTIONS OF GASES IN LIQUIDS

Henry's law states that the amount (i.e., mole fraction) of a slightly soluble gas dissolved in a liquid is proportional to the partial pressure of the gas. This law applies separately to each gas to which the liquid is exposed, as if each gas were present alone. The algebraic form of Henry's law is given by Eq. 22.7, in which H is the *Henry's law constant* in mole fractions/atmosphere.

$$x_i = Hp_i \qquad 22.7$$

Generally, the solubility of gases in liquids decreases with increasing temperature.

The volume of gas absorbed at a partial pressure of 1 atm and 0°C is known as the *absorption coefficient.* Typical absorption coefficients for solutions in water are: H_2, 0.017 1/L; He, 0.009 1/L; N_2, 0.015 1/L; O_2, 0.028 1/L; CO, 0.025 1/L; and CO_2, 0.88 1/L.

The amount of gas dissolved in a liquid varies with the temperature of the liquid and the concentration of dissolved salts in the liquid. Appendix 22.D lists the saturation values of dissolved oxygen in water at various temperatures and for various amounts of chloride ion (also referred to as *salinity*).

Example 22.6

At 20°C and 1 atm, 1 L of water will absorb 0.043 g of oxygen or 0.019 g of nitrogen. Atmospheric air is 20.9% oxygen by volume, and the remainder is assumed to be nitrogen. What masses of oxygen and nitrogen will be absorbed by 1 L of water exposed to 20°C air at 1 atm?

Solution

Since partial pressure is volumetrically weighted,

$$m_{\text{oxygen}} = (0.209)\left(0.043\ \frac{\text{g}}{\text{L}}\right) = 0.009\ \text{g/L}$$

$$m_{\text{nitrogen}} = (1.000 - 0.209)\left(0.019\ \frac{\text{g}}{\text{L}}\right) = 0.015\ \text{g/L}$$

Example 22.7

At an elevation of 4000 ft, the barometric pressure is 660 mm Hg. What is the dissolved oxygen concentration of 18°C water with a 800 mg/L chloride concentration at that elevation?

Solution

From App. 22.D, oxygen's saturation concentration for 18°C water corrected for a 800 mg/L chloride concentration is

$$C_s = 9.5\ \frac{\text{mg}}{\text{L}} - (8)\left(0.009\ \frac{\text{mg}}{\text{L}}\right) = 9.4\ \text{mg/L}$$

Use the appendix footnote to correct for the barometric pressure.

$$C_s' = \left(9.4\ \frac{\text{mg}}{\text{L}}\right)\left(\frac{660\ \text{mm} - 18\ \text{mm}}{760\ \text{mm} - 18\ \text{mm}}\right)$$
$$= 8.1\ \text{mg/L}$$

17. SOLUTIONS OF SOLIDS IN LIQUIDS

When a solid is added to a liquid, the solid is known as the *solute* and the liquid is known as the *solvent.*[12] If the dispersion of the solute throughout the solvent is at the molecular level, the mixture is known as a *solution.* If the solute particles are larger than molecules, the mixture is known as a *suspension.*[13]

In some solutions, the solvent and solute molecules bond loosely together. This loose bonding is known as *solvation.* If water is the solvent, the bonding process is also known as *aquation* or *hydration.*

The solubility of most solids in liquid solvents usually increases with increasing temperature. Pressure has very little effect on the solubility of solids in liquids.

[12]The term *solvent* is often associated with volatile liquids, but the term is more general than that. (A *volatile liquid* evaporates rapidly and readily at normal temperatures.) Water is the solvent in aqueous solutions.

[13]An *emulsion* is not a mixture of a solid in a liquid. It is a mixture of two immiscible liquids.

When the solvent has dissolved as much solute as it can, it is a *saturated solution.*[14] Adding more solute to an already saturated solution will cause the excess solute to settle to the bottom of the container, a process known as *precipitation.* Other changes (in temperature, concentration, etc.) can be made to cause precipitation from saturated and unsaturated solutions.

18. UNITS OF CONCENTRATION

There are many units of concentration to express solution strengths.

F— *formality:* The number of gram formula weights (i.e., molecular weights in grams) per liter of solution.

m— *molality:* The number of gram-moles of solute per 1000 grams of solvent. A "molal" solution contains 1 gram-mole per 1000 grams of solvent.

M— *molarity:* The number of gram-moles of solute per liter of solution. A "molar" (i.e., 1 M) solution contains 1 gram-mole per liter of solution. Molarity is related to normality: $N = M \times \Delta$ oxidation number.

N— *normality:* The number of gram equivalent weights of solute per liter of solution. A solution is "normal" (i.e., 1 *N*) if there is exactly one gram equivalent weight per liter of solution.

x— *mole fraction:* The number of moles of solute divided by the number of moles of solvent and all solutes.

meq/L— *milligram equivalent weights* of solute *per liter* of solution: calculated by multiplying normality by 1000 or dividing concentration in mg/L by equivalent weight.

mg/L— *milligrams per liter:* The number of milligrams of solute per liter of solution. Same as ppm for solutions of water.

ppm— *parts per million:* The number of pounds (or grams) of solute per million pounds (or grams) of solution. Same as mg/L for solutions of water.

For compounds whose molecules do not dissociate in solution (e.g., table sugar), there is no difference between molarity and formality. There is a difference, however, for compounds that dissociate into ions (e.g., table salt). Consider a solution derived from 1 gmol of magnesium nitrate $Mg(NO_3)_2$ in enough water to bring the volume to 1 L. The formality is 1.0 (i.e., the solution is 1.0 formal). However, 3 moles of ions will be produced—1 mole of Mg^{++} ions and 2 moles of NO_3^- ions. Therefore, molarity is 1.0 for the magnesium ion and 2.0 for the nitrate ion.

The use of formality avoids the ambiguity in specifying concentrations for ionic solutions. Also, the use of formality avoids the problem of determining a molecular weight when there are no discernible molecules (e.g., as in a crystalline solid such as NaCl). However, in their quest for uniformity in nomenclature, most modern chemists do not make the distinction between molarity and formality, and molarity is used as if it were formality.

Example 22.8

A solution is made by dissolving 0.353 g of $Al_2(SO_4)_3$ in 730 g of water. Assuming 100% ionization, what is the concentration expressed as normality, molarity, and mg/L?

Solution

The molecular weight of $Al_2(SO_4)_3$ is

$$\text{MW} = (2)(26.98) + (3)\big(32.06 + (4)(16)\big) = 342.14$$

The equivalent weight is

$$\text{EW} = \frac{342.14}{6} = 57.02$$

The number of gram equivalent weights used is

$$\frac{0.353}{57.02} = 6.19 \times 10^{-3}\ \text{GEW}$$

The number of liters of solution (same as the solvent volume if the small amount of solute is neglected) is 0.73.

The normality is

$$N = \frac{6.19 \times 10^{-3}\ \text{GEW}}{0.73\ \text{L}} = 8.48 \times 10^{-3}$$

The number of moles of solute used is 0.353 g/342.14 g/mol = 1.03×10^{-3} mol.

The molarity is

$$M = \frac{1.03 \times 10^{-3}\ \text{mol}}{0.73\ \text{L}} = 1.41 \times 10^{-3}$$

The number of milligrams is

$$\frac{0.353\ \text{g}}{0.001\ \frac{\text{g}}{\text{mg}}} = 353\ \text{mg}$$

$$\text{mg/L} = \frac{353\ \text{mg}}{0.73\ \text{L}} = 483.6$$

19. pH AND pOH

A measure of the strength of an acid or base is the number of hydrogen or hydroxide ions in a liter of solution.

[14] Under certain circumstances, a *supersaturated solution* can exist for a limited amount of time.

Since these are very small numbers, a logarithmic scale is used.

$$\text{pH} = -\log_{10}[\text{H}^+] = \log_{10}\left(\frac{1}{[\text{H}^+]}\right) \qquad 22.8$$

$$\text{pOH} = -\log_{10}[\text{OH}^-] = \log_{10}\left(\frac{1}{[\text{OH}^-]}\right) \qquad 22.9$$

The quantities $[\text{H}^+]$ and $[\text{OH}^-]$ in square brackets are the *ionic concentrations* in moles of ions per liter. The number of moles can be calculated from Avogadro's law by dividing the actual number of ions per liter by 6.022×10^{23}. Alternatively, for a partially ionized compound, X, in a solution of known molarity, M, the ionic concentration is

$$[X] = (\text{fraction ionized}) \times M \qquad 22.10$$

A *neutral solution* has a pH of 7.[15] Solutions with a pH below 7 are acidic; the smaller the pH, the more acidic the solution. Solutions with a pH above 7 are basic.

The relationship between pH and pOH is

$$\text{pH} + \text{pOH} = 14 \qquad 22.11$$

Example 22.9

A 4.2% ionized 0.01M ammonia solution is prepared from ammonium hydroxide (NH_4OH). Calculate the pH, pOH, and concentrations of H^+ and OH^-.

Solution

From Eq. 22.10,

$$\begin{aligned}[\text{OH}^-] &= (\text{fraction ionized}) \times M = (0.042)(0.01) \\ &= 4.2 \times 10^{-4}\ \text{mol/L}\end{aligned}$$

From Eq. 22.9,

$$\begin{aligned}\text{pOH} &= -\log[\text{OH}^-] = -\log\left(4.2 \times 10^{-4}\right) \\ &= 3.38\end{aligned}$$

From Eq. 22.11,

$$\begin{aligned}\text{pH} &= 14 - \text{pOH} = 14 - 3.38 \\ &= 10.62\end{aligned}$$

The $[\text{H}^+]$ ionic concentration can be extracted from the definition of pH.

$$\begin{aligned}[\text{H}^+] &= 10^{-\text{pH}} = 10^{-10.62} \\ &= 2.4 \times 10^{-11}\ \text{mol/L}\end{aligned}$$

[15]The pH of a neutral solution depends on the temperature. At 25°C, the pH is 7. When the temperature is higher (lower) than 25°C, the pH will be less (greater) than 7.

20. BUFFERS

A *buffer solution* resists changes in acidity and maintains a relatively constant pH when a small amount of an acid or base is added to it. Buffers are usually combinations of weak acids and their salts. A buffer is most effective when the acid and salt concentrations are equal.

21. NEUTRALIZATION

Acids and bases neutralize each other to form water.

$$\text{H}^+ + \text{OH}^- \longrightarrow \text{H}_2\text{O}$$

Assuming 100% ionization of the solute, the volumes, V, required for complete neutralization can be calculated from the normalities, N, or the molarities, M.

$$V_{\text{base}}N_{\text{base}} = V_{\text{acid}}N_{\text{acid}} \qquad 22.12$$

$$V_{\text{base}}M_{\text{base}}\Delta_{\text{base charge}} = V_{\text{acid}}M_{\text{acid}}\Delta_{\text{acid charge}} \qquad 22.13$$

22. REVERSIBLE REACTIONS

Reversible reactions are capable of going in either direction and do so to varying degrees (depending on the concentrations and temperature) simultaneously. These reactions are characterized by the simultaneous presence of all reactants and all products. For example, the chemical equation for the exothermic formation of ammonia from nitrogen and hydrogen is

$$\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3 + \Delta H = -24.5\ \text{kcal}$$

At *chemical equilibrium*, reactants and products are both present. However, the concentrations of the reactants and products do not change after equilibrium is reached.

23. LE CHÂTELIER'S PRINCIPLE

Le Châtelier's principle predicts the direction in which a reversible reaction at equilibrium will go when some condition (e.g., temperature, pressure, concentration) is "stressed" (i.e., changed). The principle says that when an equilibrium state is stressed by a change, a new equilibrium is formed that reduces that stress.

Consider the formation of ammonia from nitrogen and hydrogen. When the reaction proceeds in the forward direction, energy in the form of heat is released and the temperature increases. If the reaction proceeds in the reverse direction, heat is absorbed and the temperature decreases. If the system is stressed by increasing the temperature, the reaction will proceed in the reverse direction because that direction absorbs heat and reduces the temperature.

For reactions that involve gases, the reaction equation coefficients can be interpreted as volumes. In the nitrogen-hydrogen reaction, four volumes combine to form two volumes. If the equilibrium system is stressed by increasing the pressure, then the forward reaction will occur because this direction reduces the volume and pressure.[16]

If the concentration of any substance is increased, the reaction proceeds in a direction away from the substance with the increase in concentration. (For example, an increase in the concentration of the reactants shifts the equilibrium to the right, increasing the amount of products formed.)

The *common ion effect* is a special case of Le Châtelier's principle. If a salt containing a common ion is added to a solution of a weak acid, almost all of the salt will dissociate, adding large quantities of the common ion to the solution. Ionization of the acid will be greatly suppressed, a consequence of the need to have an unchanged equilibrium constant.

24. IRREVERSIBLE REACTION KINETICS

The rate at which a compound is formed or used up in an irreversible (one-way) reaction is known as the *rate of reaction*, also known as the *speed of reaction, reaction velocity*, and so on. The rate, v, is the change in concentration per unit time, usually measured in mol/L·s.

$$\text{v} = \text{change in concentration/time} \qquad 22.14$$

According to the *law of mass action*, the rate of reaction varies with the concentrations of the reactants and products. Specifically, the rate is proportional to the molar concentrations (i.e., the molarities). The rate of the formation or a conversion of substance A is represented in various forms, such as r_A, dA/dt, and $d[A]/dt$, where the variable A or [A] can represent either the mass or the concentration of substance A. Substance A can be either a pure element or a compound.

The rate of reaction is generally not affected by pressure, but does depend on five other factors.

- *type of substances in the reaction:* Some substances are more reactive than others.
- *exposed surface area:* The rate of reaction is proportional to the amount of contact between the reactants.
- *concentrations:* The rate of reaction increases with increases in concentration.
- *temperature:* The rate of reaction approximately doubles with every 10°C increase in temperature.
- *catalysts:* If a catalyst is present, the rate of reaction increases. However, the equilibrium point is not changed. (A catalyst is a substance that increases the reaction rate without being consumed in the reaction.)

[16]The exception to this rule is the addition of an inert gas to a gaseous equilibrium system. Although there is an increase in total pressure, the position of the equilibrium is not affected.

25. ORDER OF THE REACTION

The *order of the reaction* is the total number of reacting molecules in or before the slowest step in the mechanism.[17] The order must be determined experimentally. However, for an irreversible elementary reaction, the order is usually assumed from the stoichiometric reaction equation as the sum of the combining coefficients for the reactants.[18,19] For example, for the reaction $mA + nB \rightarrow pC$, the overall order of the forward reaction is assumed to be $m + n$.

Many reactions (e.g., dissolving metals in acid or the evaporation of condensed materials) have *zero-order reaction rates.* These reactions do not depend on the concentrations or temperature at all, but rather, are affected by other factors such as the availability of reactive surfaces or the absorption of radiation. The formation (conversion) rate of a compound in a zero-order reaction is constant. That is, $dA/dt = -k_0$. k_0 is known as the *reaction rate constant.* (The subscript "0" refers to the zero-order.) Since the concentration (amount) of the substance decreases with time, dA/dt is negative. Since the negative sign is explicit in rate equations, the reaction rate constant is always considered to be a positive number.

Table 22.2 contains reaction rate and half-life equations for various types of low-order reactions. Once a reaction rate equation is known, it can be integrated to obtain an expression for the concentration (mass) of the substance at various times. The time for half of the substance to be formed (or converted) is the *half-life*, $t_{1/2}$.

Example 22.10

Nitrogen pentoxide decomposes according to the following first-order reaction.

$$N_2O_5 \rightarrow 2NO_2 + \tfrac{1}{2}O_2$$

At a particular temperature, the decomposition of nitrogen pentoxide is 85% complete at the end of 11 min. The reaction rate constant is to be determined.

[17]This definition is valid for elementary reactions. For complex reactions, the order is an empirical number that need not be an integer.

[18]The overall order of the reaction is the sum of the orders with respect to the individual reactants. For example, in the reaction $2NO + O_2 \rightarrow 2NO_2$, the reaction is second order with respect to NO, first order with respect to O_2, and third order overall.

[19]In practice, the order of the reaction must be known, given, or determined experimentally. It is not always equal to the sum of the combining coefficients for the reactants. For example, in the reaction $H_2 + I_2 \rightarrow 2HI$, the overall order of the reaction is indeed 2, as expected. However, in the reaction $H_2 + Br_2 \rightarrow 2HBr$, the overall order is found experimentally to be 3/2, even though the two reactions have the same stoichiometry, and despite the similarities of iodine and bromine.

Table 22.2 *Reaction Rates and Half-Life Equations*

reaction	order	rate equation	integrated forms
$A \rightarrow B$	zero	$\frac{d[A]}{dt} = -k_0$	$[A] = [A]_0 - k_0 t$ $t_{1/2} = \frac{[A]_0}{2k_0}$
$A \rightarrow B$	first	$\frac{d[A]}{dt} = -k_1[A]$	$\ln \frac{[A]}{[A]_0} = k_1 t$ $t_{1/2} = \frac{1}{k_1} \ln 2$
$A + A \rightarrow P$	second, type I	$\frac{d[A]}{dt} = -k_2[A]^2$	$\frac{1}{[A]} - \frac{1}{[A]_0} = k_2 t$ $t_{1/2} = \frac{1}{k_2[A]_0}$
$aA + bB \rightarrow P$	second, type II	$\frac{d[A]}{dt} = -k_2[A][B]$	$\ln \frac{[A]_0 - [B]}{[B]_0 - \left(\frac{b}{a}\right)[X]} = \ln \frac{[A]}{[B]}$ $= \left(\frac{b[A]_0 - a[B]_0}{a}\right) k_2 t + \ln \frac{[A]_0}{[B]_0}$ $t_{1/2} = \left[\frac{a}{k_2(b[A]_0 - a[B]_0)}\right]$ $\times \ln \left[\frac{a[B]_0}{2a[B]_0 - b[A]_0}\right]$

Solution

The reaction is given as first order. Use the integrated reaction rate equation from Table 22.2. Since the decomposition reaction is 85% complete, the surviving fraction is 15% (0.15).

$$\ln\left(\frac{[A]}{[A]_0}\right) = k_1 t$$
$$\ln(0.15) = k(11 \text{ min})$$
$$k = -0.172 \text{ 1/min} \quad (0.172 \text{ 1/min})$$

(The rate constant is considered to be a positive number.)

26. REVERSIBLE REACTION KINETICS

Consider the following reversible reaction.

$$aA + bB \rightleftharpoons cC + dD \qquad 22.15$$

In Eqs. 22.16 and 22.17, the constants k_{forward} and k_{reverse} are the *reaction rate constants*. The order of the forward reaction is $a+b$; the order of the reverse reaction is $c+d$.

$$v_{\text{forward}} = k_{\text{forward}}[A]^a[B]^b \qquad 22.16$$
$$v_{\text{reverse}} = k_{\text{reverse}}[C]^c[D]^d \qquad 22.17$$

At equilibrium, the forward and reverse speeds of reaction are equal.

$$v_{\text{forward}} = v_{\text{reverse}}\big|_{\text{equilibrium}} \qquad 22.18$$

27. EQUILIBRIUM CONSTANT

For reversible reactions, the *equilibrium constant*, K, is proportional to the ratio of the reverse rate of reaction to the forward rate of reaction.[20] Except for catalysis, the equilibrium constant depends on the same factors affecting the reaction rate. For the complex reversible reaction given by Eq. 22.15, the equilibrium constant is given by the *law of mass action*.

$$K = \frac{[C]^c[D]^d}{[A]^a[B]^b} = \frac{k_{\text{forward}}}{k_{\text{reverse}}} \qquad 22.19$$

If any of the reactants or products are in pure solid or pure liquid phases, their concentrations are omitted from the calculation of the equilibrium constant. For example, in weak aqueous solutions, the concentration of water, H_2O, is very large and essentially constant; therefore, that concentration is omitted.

[20]The symbols K_c (in molarity units) and K_{eq} are occasionally used for the equilibrium constant.

For gaseous reactants and products, the concentrations (i.e., the numbers of atoms) will be proportional to the partial pressures. Therefore, an equilibrium constant can be calculated directly from the partial pressures and is given the symbol K_p. For example, for the formation of ammonia gas from nitrogen and hydrogen, the equilibrium constant is

$$K_p = \frac{[p_{NH_3}]^2}{[p_{N_2}][p_{H_2}]^3} \qquad 22.20$$

K and K_p are not numerically the same, but they are related by Eq. 22.21. Δn is the number of moles of products minus the number of moles of reactants.

$$K_p = K(R^*T)^{\Delta n} \qquad 22.21$$

Example 22.11

A particularly weak solution of acetic acid ($HC_2H_3O_2$) in water has the ionic concentrations (in mol/L) given. What is the equilibrium constant?

$$HC_2H_3O_2 + H_2O \rightleftarrows H_3O^+ + C_2H_3O_2^-$$

$$[HC_2H_3O_2] = 0.09866$$
$$[H_2O] = 55.5555$$
$$[H_3O^+] = 0.00134$$
$$[C_2H_3O_2^-] = 0.00134$$

Solution

The concentration of the water molecules is not included in the calculation of the equilibrium or ionization constant. Therefore, the equilibrium constant is

$$K = K_a = \frac{[H_3O^+][C_2H_3O_2^-]}{[HC_2H_3O_2]} = \frac{(0.00134)(0.00134)}{0.09866} = 1.82 \times 10^{-5}$$

28. IONIZATION CONSTANT

The equilibrium constant for a weak solution is essentially constant and is known as the *ionization constant* (also known as a *dissociation constant*). For weak acids, the symbol K_a and name *acid constant* are used. For weak bases, the symbol K_b and the name *base constant* are used. For example, for the ionization of hydrocyanic acid,

$$HCN \rightleftarrows H^+ + CN^-$$

$$K_a = \frac{[H^+][CN^-]}{[HCN]}$$

Pure water is itself a very weak electrolyte and ionizes only slightly.

$$2H_2O \rightleftarrows H_3O^+ + OH^- \qquad 22.22$$

At equilibrium, the ionic concentrations are equal.

$$[H_3O^+] = 10^{-7}$$
$$[OH^-] = 10^{-7}$$

From Eq. 22.19, the ionization constant (*ion product*) for pure water is

$$K_w = K_{a,water} = [H_3O^+][OH^-] = (10^{-7})(10^{-7}) = 10^{-14} \qquad 22.23$$

If the molarity, M, and fraction ionization, X, are known, the ionization constant can be calculated from Eq. 22.24.

$$K_{ionization} = \frac{MX^2}{1 - X} \qquad 22.24$$

The reciprocal of the ionization constant is the *stability constant* (*overall stability constant*), also known as the *formation constant*. Stability constants are used to describe complex ions that dissociate readily.

Table 22.3 *Approximate Ionization Constants*

substance	0°C	5°C	10°C	15°C	20°C	25°C
$Ca(OH)_2$						3.74×10^{-3}
HClO	2.0×10^{-8}	2.3×10^{-8}	2.6×10^{-8}	3.0×10^{-8}	3.3×10^{-8}	3.7×10^{-8}
$HC_2H_3O_2$	1.67×10^{-5}	1.70×10^{-5}	1.73×10^{-5}	1.75×10^{-5}	1.75×10^{-5}	1.75×10^{-5}
HBrO					$\approx 2 \times 10^{-9}$	
H_2CO_3 (K_1)	2.6×10^{-7}	3.04×10^{-7}	3.44×10^{-7}	3.81×10^{-7}	4.16×10^{-7}	4.45×10^{-7}
$HClO_2$					$\approx 1.1 \times 10^{-2}$	
NH_3	1.37×10^{-5}	1.48×10^{-5}	1.57×10^{-5}	1.65×10^{-5}	1.71×10^{-5}	1.77×10^{-5}
NH_4OH						1.79×10^{-5}
water[a]	14.9435	14.7338	14.5346	14.3463	14.1669	13.9965

[a] $-\log_{10}(K)$ given

Example 22.12

A 0.1 molar (0.1M) acetic acid solution is 1.34% ionized. Find the (a) hydrogen ion concentration, (b) acetate ion concentration, (c) un-ionized acid concentration, and (d) ionization constant.

Solution

(a) From Eq. 22.10, the hydrogen ion concentration is

$$\begin{aligned}[H_3O^+] &= (\text{fraction ionized})\,(\text{molarity}) \\ &= (0.0134)(0.1) = 0.00134 \text{ mol/L}\end{aligned}$$

(b) Since every hydronium ion has a corresponding acetate ion, the acetate and hydronium ion concentrations are the same.

$$[C_2H_3O_2^-] = [H_3O^+] = 0.00134 \text{ mol/L}$$

(c) The concentration of un-ionized acid can be derived from Eq. 22.10.

$$\begin{aligned}[HC_2H_3O_2] &= (\text{fraction not ionized})\,(\text{molarity}) \\ &= (1 - 0.0134)(0.1) = 0.09866 \text{ mol/L}\end{aligned}$$

(d) The ionization constant is calculated from Eq. 22.24.

$$\begin{aligned}K_a &= \frac{(\text{molarity})\,(\text{fraction ionized})^2}{1 - \text{fraction ionized}} \\ &= \frac{(0.1)(0.0134)^2}{1 - 0.0134} = 1.82 \times 10^{-5}\end{aligned}$$

Example 22.13

The ionization constant for acetic acid is 1.82×10^{-5}. What is the hydrogen ion concentration for a 0.2M solution?

Solution

From Eq. 22.24,

$$K_a = \frac{MX^2}{1 - X}$$

$$1.82 \times 10^{-5} = \frac{0.2X^2}{1 - X}$$

Since acetic acid is a weak acid, X is known to be small. Therefore, the computational effort can be reduced by assuming that $1 - X \approx 1$.

$$1.82 \times 10^{-5} = 0.2X^2$$

$$X = 9.49 \times 10^{-3}$$

From Eq. 22.10, the concentration of the hydrogen ion is

$$\begin{aligned}[H_3O^+] &= XM = (9.49 \times 10^{-3})(0.2) \\ &= 1.9 \times 10^{-3} \text{ mol/L}\end{aligned}$$

Example 22.14

The ionization constant for acetic acid ($HC_2H_3O_2$) is 1.82×10^{-5}. What is the hydrogen ion concentration of a solution with 0.1 mole of 80% ionized ammonium acetate ($NH_4C_2H_3O_2$) in 1 L of 0.1M acetic acid?

Solution

The acetate ion ($C_2H_3O_2^-$) is a *common ion*, since it is supplied by both the acetic acid and the ammonium acetate. Both sources contribute to the ionic concentration. However, the ammonium acetate's contribution dominates. Since the acid dissociates into an equal number of hydrogen and acetate ions,

$$\begin{aligned}[C_2H_3O_2^-]_{\text{total}} &= [C_2H_3O_2^-]_{\text{acid}} \\ &\quad + [C_2H_3O_2^-]_{\text{ammonium acetate}} \\ &= [H_3O^+] + (0.8)(0.1) \\ &\approx (0.8)(0.1) = 0.08\end{aligned}$$

As a result of the common ion effect and Le Châtelier's law, the acid's dissociation is essentially suppressed by the addition of the ammonium acetate. The concentration of un-ionized acid is

$$\begin{aligned}[HC_2H_3O_2] &= 0.1 - [H_3O^+] \\ &\approx 0.1\end{aligned}$$

The ionization constant is unaffected by the number of sources of the acetate ion.

$$K_a = \frac{[H_3O^+][C_2H_3O_2^-]}{[HC_2H_3O_2]}$$

$$1.82 \times 10^{-5} = \frac{[H_3O^+] \times 0.08}{0.1}$$

$$[H_3O^+] = 2.3 \times 10^{-5} \text{ mol/L}$$

29. IONIZATION CONSTANTS FOR POLYPROTIC ACIDS

A polyprotic acid has as many ionization constants as it has acidic hydrogen atoms. For oxyacids, each successive ionization constant is approximately 10^5 times smaller than the preceding one. For example, phosphoric acid (H_3PO_4) has three ionization constants:

$$\begin{aligned}K_1 &= 7.1 \times 10^{-3} \quad (H_3PO_4) \\ K_2 &= 6.3 \times 10^{-8} \quad (H_2PO_4^-) \\ K_3 &= 4.4 \times 10^{-13} \quad (HPO_4^{-2})\end{aligned}$$

30. SOLUBILITY PRODUCT

When an ionic solid is dissolved in a solvent, it dissociates. For example, consider the ionization of silver chloride in water.

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$$

If the equilibrium constant is calculated, the terms for pure solids and liquids (in this case, [AgCl] and [H_2O]) are omitted. Thus, the *solubility product*, K_{sp}, consists only of the ionic concentrations. As with the general case of ionization constants, the solubility product for slightly soluble solutes is essentially constant at a standard value.

$$K_{sp} = [Ag^+][Cl^-] \qquad 22.25$$

When the product of terms exceeds the standard value of the solubility product, solute will precipitate out until the product of the remaining ion concentrations attains the standard value. If the product is less than the standard value, the solution is not saturated.

The solubility products of nonhydrolyzing compounds are relatively easy to calculate. (Example 22.14 illustrates a method.) Such is the case for chromates (CrO_4^{-2}), halides (F^-, Cl^-, Br^-, I^-), sulfates (SO_4^{-2}), and iodates (IO_3^-). However, compounds that hydrolyze must be treated differently. The method used in Ex. 22.14 cannot be used for hydrolyzing compounds.

Example 22.15

At a particular temperature, it takes 0.038 grams of lead sulfate ($PbSO_4$, molecular weight = 303.25) per liter of water to prepare a saturated solution. What is the solubility product of lead sulfate if all of the lead sulfate ionizes?

Solution

Sulfates are not one of the hydrolyzing ions. Therefore, the solubility product can be calculated from the concentrations.

Since 1 L of water has a mass of 1 kg, the number of moles of lead sulfate dissolved per saturated liter of solution is

$$n = \frac{m}{\text{MW}} = \frac{0.038 \text{ g}}{303.25 \frac{\text{g}}{\text{mol}}}$$
$$= 1.25 \times 10^{-4} \text{ mol}$$

Lead sulfate ionizes according to the following reaction.

$$PbSO_4(s) \rightleftharpoons Pb^{+2}(aq) + SO_4^-(aq) \quad \text{[in water]}$$

Since all of the lead sulfate ionizes, the number of moles of each ion is the same as the number of moles of lead sulfate. Therefore,

$$K_{sp} = [Pb^{+2}][SO_4^{-2}] = (1.25 \times 10^{-4})(1.25 \times 10^{-4})$$
$$= 1.56 \times 10^{-8}$$

31. ENTHALPY OF FORMATION

Enthalpy, H, is the potential energy that a substance possesses by virtue of its temperature, pressure, and phase.[21] The *enthalpy of formation* (*heat of formation*), ΔH_f, of a compound is the energy absorbed during the formation of 1 gmol of the compound from the elements.[22] The enthalpy of formation is assigned a value of zero for elements in their free states at 25°C and 1 atm. This is the so-called *standard state* for enthalpies of formation.

Table 22.4 contains enthalpies of formation for some common elements and compounds. The enthalpy of formation depends on the temperature and phase of the compound. A standard temperature of 25°C is used in most tables of enthalpies of formation.[23] Compounds are solid (s) unless indicated to be gaseous (g) or liquid (l). Some aqueous (aq) values are also encountered.

32. ENTHALPY OF REACTION

The *enthalpy of reaction* (*heat of reaction*), ΔH_r, is the energy absorbed during a chemical reaction under constant volume conditions. It is found by summing the enthalpies of formation of all products and subtracting the sum of enthalpies of formation of all reactants. This is essentially a restatement of the energy conservation principle and is known as *Hess' law of energy summation.*

$$\Delta H_r = \sum \Delta H_{f,\text{products}} - \sum \Delta H_{f,\text{reactants}} \qquad 22.26$$

Reactions that give off energy (i.e., have negative enthalpies of reaction) are known as *exothermic reactions.* Many (but not all) exothermic reactions begin spontaneously. On the other hand, *endothermic reactions* absorb energy and require heat or electrical energy to begin.

Example 22.16

Using enthalpies of formation, calculate the heat of stoichiometric combustion (standardized to 25°C) of gaseous methane (CH_4) and oxygen.

Solution

The balanced chemical equation for the stoichiometric combustion of methane is

$$CH_4 + 2O_2 \longrightarrow 2H_2O + CO_2$$

[21] The older term *heat* is rarely encountered today.
[22] The symbol H is used to denote molar enthalpies. The symbol h is used for specific enthalpies (i.e., energy per kilogram or per pound).
[23] It is possible to correct the enthalpies of formation to account for other reaction temperatures.

Table 22.4 *Standard Enthalpies of Formation (kcal/mol at 25°C)*

element/compound	ΔH_f
Al (*s*)	0.00

H_2O_2 (*g*)	−31.83
H_2S (*g*)	−4.82
N_2 (*g*)	0.00
NO (*g*)	21.60
NO_2 (*g*)	8.09
NO_3 (*g*)	13
NH_3 (*g*)	−11.04
O_2 (*g*)	0.00
O_3 (*g*)	34.0
S (*s*)	0.00
SO_2 (*g*)	−70.96
SO_3 (*g*)	−94.45

(Multiply kcal/mol by 1800/MW to obtain Btu/lbm.)

Using the footnote to Table 22.4, this value can be converted to Btu/lbm. The molecular weight of methane is

$$\mathrm{MW}_{CH_4} = 12 + (4)(1) = 16$$

$$\text{higher heating value} = \frac{\left(191.75\ \frac{\text{kcal}}{\text{mol}}\right)(1800)}{16}$$

$$= 21{,}570\ \text{Btu/lbm}$$

Using enthalpies of formation from Table 22.4 in Eq. 22.13, the enthalpy of reaction per mole of methane is

$$\begin{aligned}\Delta H_r &= 2\Delta H_{f,H_2O} + \Delta H_{f,CO_2} - \Delta H_{f,CH_4} \\ &\quad - 2\Delta H_{f,O_2} \\ &= (2)\left(-57.80\ \frac{\text{kcal}}{\text{mol}}\right) + \left(-94.05\ \frac{\text{kcal}}{\text{mol}}\right) \\ &\quad - \left(-17.90\ \frac{\text{kcal}}{\text{mol}}\right) - (2)(0) \\ &= -191.75\ \text{kcal/mol}\ CH_4 \quad \text{[exothermic]}\end{aligned}$$

Notice that the enthalpy of formation of oxygen gas (its free-state configuration) is zero.

33. CORROSION

Corrosion is an undesirable degradation of a material resulting from a chemical or physical reaction with the environment. Conditions within the crystalline structure can accentuate or retard corrosion. The main types of corrosion are listed in subsequent sections. Corrosion rates are reported in units of mils per year (mpy) and micrometers per year (μm/y).

34. UNIFORM ATTACK CORROSION

Uniform rusting of steel and oxidation of aluminum over entire exposed surfaces are examples of *uniform attack corrosion.* Uniform attack is usually prevented by the use of paint, plating, and other protective coatings.

35. INTERGRANULAR CORROSION

Some metals are particularly sensitive to *intergranular corrosion,* IGC—selective or localized attack at metal-grain boundaries. For example, the Cr_2O_3 oxide film on stainless steel contains numerous imperfections at grain boundaries, and these boundaries can be attacked and enlarged by chlorides.

Intergranular corrosion may occur after a metal has been heated, in which case it may be known as *weld decay.* In the case of type 304 austenitic stainless steels, heating to 930 to 1300°F (500 to 700°C) in a welding process causes chromium carbides to precipitate out,

reducing the corrosion resistance.[24] Reheating to 1830 to 2010°F (1000 to 1100°C) followed by rapid cooling will redissolve the chromium carbides and restore corrosion resistance.

36. PITTING

Pitting is a localized perforation on the surface. It can occur even where there is little or no other visible damage. Chlorides and other halogens (e.g., HF and HCl) in the presence of water foster pitting in passive alloys, especially in stainless steels and aluminum alloys.

37. CONCENTRATION-CELL CORROSION

Concentration-cell corrosion (also known as *crevice corrosion* and *intergranular attack*, IGA) occurs when a metal is in contact with different electrolyte concentrations. It usually occurs in crevices, between two assembled parts, under riveted joints, or where there are scale and surface deposits that create stagnant areas in a corrosive medium.

38. EROSION CORROSION

Erosion corrosion is the deterioration of metals buffeted by the entrained solids in a corrosive medium.

39. SELECTIVE LEACHING

Selective leaching is the dealloying process in which one of the alloy ingredients is removed from the solid solution. This occurs because the lost ingredient has a lower corrosion resistance than the remaining ingredient. *Dezincification* is the classic case where zinc is selectively destroyed in brass. Other examples are the dealloying of nickel from copper-nickel alloys, iron from steel, and aluminum from copper-aluminum alloys.

40. HYDROGEN EMBRITTLEMENT

Hydrogen damage occurs when hydrogen gas diffuses through and decarburizes steel (i.e., reacts with carbon to form methane). *Hydrogen embrittlement* (also known as *caustic embrittlement*) is hydrogen damage from hydrogen produced by caustic corrosion.

41. GALVANIC ACTION

Galvanic action (*galvanic corrosion* or *two-metal corrosion*) results from the difference in oxidation potentials of metallic ions. The greater the difference in oxidation potentials, the greater will be the galvanic corrosion. If two metals with different oxidation potentials are placed in an electrolytic medium (e.g., seawater), a galvanic cell will be created. The metal with the higher potential (i.e., the more "noble" metal) will act as an anode and will corrode. The metal with the lower potential, being the cathode, will be unchanged. In one extreme type of intergranular corrosion known as *exfoliation*, open endgrains separate into layers.

Metals are often classified according to their positions in the *galvanic series* listed in Table 22.5. As would be expected, the metals in this series are in approximately the same order as their half-cell potentials. However, alloys and proprietary metals are also included in the series.

Table 22.5 *Galvanic Series in Seawater (anodic to cathodic)*

graphite
gold

Precautionary measures can be taken to inhibit or eliminate galvanic action when use of dissimilar metals is unavoidable.

- Use dissimilar metals that are close neighbors in the galvanic series.

[24] *Austenitic stainless steels* are the 300 series. They consist of chromium nickel alloys with up to 8% nickel. They are not hardenable by heat treatment, are nonmagnetic, and offer the greatest resistance to corrosion. *Martensitic stainless steels* are hardenable and magnetic. *Ferritic stainless steels* are magnetic and not hardenable.

- Use *sacrificial anodes.* In marine saltwater applications, sacrificial zinc plates can be used.
- Use protective coatings, oxides, platings, or inert spacers to reduce or eliminate the access of corrosive environments to the metals.[25]

42. STRESS CORROSION

When subjected to sustained surface tensile stresses (including low residual stresses from manufacturing) in corrosive environments, certain metals exhibit catastrophic *stress corrosion* cracking, SCC. When the stresses are cyclic, this type of corrosion is called *corrosion fatigue*, which can lead to fatigue failures well below normal yield stresses.

Stress corrosion occurs because the more highly stressed grains (at the crack tip) are slightly more anodic than neighboring grains with lower stresses. Although intergranular cracking (at grain boundaries) is more common, corrosion cracking may be *intergranular* (between the grains), *transgranular* (through the grains), or a combination of the two, depending on the alloy. Cracks propagate, often with extensive branching, until failure occurs.

The precautionary measures that can be taken to inhibit or eliminate stress corrosion are as follows.

- Avoid using metals that are susceptible to stress corrosion. These include austenitic stainless steels without heat treatment in seawater; certain tempers of the aluminum alloys 2124, 2219, 7049, and 7075 in seawater; and copper alloys exposed to ammonia.
- Protect open-grain surfaces from the environment. For example, press-fitted parts in drilled holes can be assembled with wet zinc chromate paste. Also, weldable aluminum can be "buttered" with pure aluminum rod.
- Stress-relieve by annealing heat treatment after welding or cold working.

43. FRETTING CORROSION

Fretting corrosion occurs when two highly loaded members have a common surface at which rubbing and sliding take place. The phenomenon is a combination of wear and chemical corrosion. Metals that depend on a film of surface oxide for protection, such as aluminum and stainless steel, are especially susceptible.

Fretting corrosion can be reduced by the following methods.

- Lubricate the rubbing surfaces.
- Seal the surfaces.
- Reduce vibration and movement.

44. CAVITATION CORROSION

Cavitation is the formation and collapse of minute bubbles of vapor in liquids. It is caused by a combination of reduced pressure and increased velocity in the fluid. In effect, very small amounts of the fluid vaporize (i.e., boil) and almost immediately condense. The repeated collapse of the bubbles hammers and work-hardens the surface.

When the surface work-hardens, it becomes brittle. Small amounts of the surface flake away, and the surface becomes pitted. This is known as *cavitation corrosion.* Eventually, the entire piece may work-harden and become brittle, leading to structural failure.

PRACTICE PROBLEMS

Empirical Formula Development

1. The gravimetric analysis of a compound is 40% carbon, 6.7% hydrogen, and 53.3% oxygen. What is the simplest formula for the compound?

(A) HCO
(B) HCO_2
(C) CH_2O
(D) CHO_2

The answer is (C).

[25]While cadmium, nickel, chromium, and zinc are often used as protective deposits on steel, porosities in the surfaces can act as small galvanic cells, resulting in invisible subsurface corrosion.

23 Organic Chemistry

1. Introduction to Organic Chemistry 23-1
2. Functional Groups 23-1
3. Families of Organic Compounds 23-1
4. Symbolic Representation 23-1
5. Formation of Organic Compounds 23-1

1. INTRODUCTION TO ORGANIC CHEMISTRY

Organic chemistry deals with the formation and reaction of compounds of carbon, many of which are produced by living organisms. Organic compounds typically have one or more of the following characteristics.

- They are insoluble in water.[1]
- They are soluble in concentrated acids.
- They are relatively nonionizing.
- They are unstable at high temperatures.

The method of naming organic compounds was standardized in 1930 at the International Union Chemistry meeting in Belgium. Names conforming to the established guidelines are known as *IUC names* or *IUPAC names.*[2]

2. FUNCTIONAL GROUPS

Certain combinations of atoms occur repeatedly in organic compounds and remain intact during reactions. Such combinations are called *functional groups.* For example, the radical OH^- is known as a *hydroxyl group.* Table 23.1 contains the most important functional groups.

3. FAMILIES OF ORGANIC COMPOUNDS

For convenience, organic compounds are categorized into families. Compounds within each family have similar structures, being based on similar combinations of groups. For example, all alcohols have the structure [R]-OH, where [R] is any alkyl group and -OH is the hydroxyl group.

[1]This is especially true for hydrocarbons. However, many organic compounds containing oxygen are water soluble. The sugar family is an example of water-soluble compounds.
[2]IUPAC stands for *International Union of Pure and Applied Chemistry.*

Table 23.1 *Functional Groups*

name	standard symbol	formula	number of single bonding sites
aldehyde		CHO	1
alkyl	[R]	C_nH_{2n+1}	1
alkoxy	[RO]	$C_nH_{2n+1}O$	1
amine (amino, $n = 2$)		NH_n	$3 - n$ $[n = 0, 1, 2]$
aryl (benzene ring)	[Ar]	C_6H_5	1
carbinol		COH	3
carbonyl (keto)		CO	2
carboxyl		COOH	1
ester		COO	1
ether		O	2
halogen (halide)	[X]	Cl, Br, I, or F	1
hydroxyl		OH	1
nitrile		CN	1
nitro		NO_2	1

Families of compounds can be further subdivided into subfamilies. For example, the hydrocarbons are classified into alkanes (single carbon-carbon bond), alkenes (double carbon-carbon bond), and alkynes (triple carbon-carbon bond).[3]

Table 23.2 contains the most common organic families.

4. SYMBOLIC REPRESENTATION

The nature and structure of organic groups and families cannot be explained fully without showing the types of bonds between the elements. Figure 23.1 illustrates the symbolic representation of some of the functional groups and families.

5. FORMATION OF ORGANIC COMPOUNDS

There are usually many ways of producing an organic compound. The types of reactions contained in this section deal only with the interactions between the organic families. The following processes are referred to.

[3]Hydrocarbons with two double carbon-carbon bonds are known as *dienes.*

Table 23.2 *Families of Organic Compounds*

family	structure	example
acids		
carboxylic acids	[R]-COOH	acetic acid ($(CH_3)COOH$)
fatty acids	[Ar]-COOH	benzoic acid (C_6H_5COOH)
alcohols		
aliphatic	[R]-OH	methanol (CH_3OH)
aromatic	[Ar]-[R]-OH	benzyl alcohol ($C_6H_5CH_2OH$)
aldehydes	[R]-CHO	formaldehyde (HCHO)
alkyl halides		
(haloalkane)	[R]-[X]	chloromethane (CH_3Cl)
amides	$[R]$-CO-NH_n	β-methylbutyramide ($C_4H_9CONH_2$)
amines	$[R]_{3-n}$-NH_n	methylamine (CH_3NH_2)
	$[Ar]_{3-n}$-NH_n	aniline ($C_6H_5NH_2$)
primary amines	$n = 2$	
secondary amines	$n = 1$	
tertiary amines	$n = 0$	
amino acids	CH-[R]-$(NH_2)COOH$	glycine ($CH_2(NH_2)COOH$)
anhydrides	[R]-CO-O-CO-[R′]	acetic anhydride $(CH_3CO)_2O$
arene (aromatics)	$ArH = C_nH_{2n-6}$	benzene (C_6H_6)
aryl halides	[Ar]-[X]	fluorobenzene (C_6H_5F)
carbohydrates	$C_x(H_2O)_y$	dextrose ($C_6H_{12}O_6$)
sugars

1. HYDROCARBONS

With the exception of sulfur and related compounds, most fuels are hydrocarbons. Hydrocarbons are further categorized into subfamilies such as *alkynes* (C_nH_{2n-2}, such as acetylene C_2H_2), *alkenes* (C_nH_{2n}, such as ethylene C_2H_4), and *alkanes* (C_nH_{2n+2}, such as octane C_8H_{18}). The alkynes and alkenes are referred to as *unsaturated hydrocarbons*, while the alkanes are referred to as *saturated hydrocarbons*. The alkanes are also known

Table 24.1 *Approximate Specific Heats (at constant pressure) of Gases (c_p in Btu/lbm-°R; at 1 atm)*

(Multiply Btu/lbm-°R by 4.187 to obtain kJ/kg·K.)

as the *paraffin series* and *methane series*. The alkenes are subdivided into the chain-structured *olefin series* and the ring-structured *naphthalene series*. *Aromatic hydrocarbons* (C_nH_{2n-6}, such as benzene C_6H_6) constitute another subfamily. Names for common hydrocarbon compounds are listed in App. 24.A.

2. CRACKING OF HYDROCARBONS

Cracking is the process of splitting hydrocarbon molecules into smaller molecules. For example, alkane molecules crack into a smaller member of the alkane subfamily and a member of the alkene subfamily. Cracking is used to obtain lighter hydrocarbons (such as those used in gasoline) from heavy hydrocarbons (e.g., crude oil).

Cracking can proceed under the influence of high temperatures (*thermal cracking*) or catalysts (*catalytic cracking* or "cat cracking"). Since (from Le Châtelier's principle) cracking at high pressure favors recombination, catalytic cracking is performed at pressures near atmospheric. Catalytic cracking also produces gasolines with better antiknock properties than does thermal cracking.

3. FUEL ANALYSIS

Fuels analyses are reported as either percentages by weight (for liquid and solid fuels) or percentages by volume (for gaseous fuels). Percentages by weight are known as *gravimetric analyses*, while percentages by volume are known as *volumetric analyses*. An *ultimate analysis* is a special type of gravimetric analysis in which the constituents are reported by atomic species rather than by compound. In an ultimate analysis, combined hydrogen from moisture in the fuel is added to hydrogen from the combustive compounds. (See Sec. 6.)

A *proximate analysis* (not "approximate") gives the gravimetric fraction of moisture, volatile matter, fixed carbon, and ash. Sulfur may be combined with the ash or may be specified separately.

Gas analyses are typically specified as volumetric fractions. For a gas in a mixture, its *volumetric fraction* (i.e., its volumetric percentage) is the same as its *mole fraction* and *partial pressure fraction*.

A volumetric fraction can be converted to a gravimetric fraction by multiplying by the molecular weight and then dividing by the sum of the products of all the volumetric fractions and molecular weights.

4. WEIGHTING OF THERMODYNAMIC PROPERTIES

Many gaseous fuels (and all gaseous combustion products) are mixtures of different compounds. Some thermodynamic properties of mixtures are gravimetrically weighted, while others are volumetrically weighted. Specific heat, specific gas constant, enthalpy, internal energy, and entropy are gravimetrically weighted. For gases, molecular weight, density, and all molar properties are volumetrically weighted.[1]

When a compound experiences a large temperature change, the thermodynamic properties should be evaluated at the average temperature. Table 24.1 can be used to find the specific heat of gases at various temperatures.

5. STANDARD CONDITIONS

Though "standard conditions" usually means 70°F (21°C) and 1 atm pressure, *standard temperature and pressure*, STP, for manufactured fuel gases is 60°F (16°C) and 1 atm pressure. Since this convention is not

[1] For gases, molar properties include molar specific heats, enthalpy per mole, and internal energy per mole.

well standardized, the actual temperature and pressure should be stated.[2]

Some combustion equipment (e.g., particulate collectors) operates within a narrow range of temperatures and pressures. These conditions are referred to as *normal temperature and pressure*, NTP.

6. MOISTURE

If an ultimate analysis of a solid or liquid fuel is given, all of the oxygen is assumed to be in the form of free water.[3] The amount of hydrogen combined as free water is assumed to be one-eighth of the oxygen weight.[4] All remaining hydrogen, known as the *available hydrogen*, is assumed to be combustible.

$$G_{\mathrm{H,combined}} = \frac{G_{\mathrm{O}}}{8} \qquad 24.1$$

$$G_{\mathrm{H,available}} = G_{\mathrm{H,total}} - \frac{G_{\mathrm{O}}}{8} \qquad 24.2$$

For coal, the *"bed" moisture level* refers to the moisture level when the coal is mined. The terms *dry* and *as fired* are often used in commercial coal specifications. The "as fired" condition corresponds to a specific moisture content when placed in the furnace. The "as fired" heating value should be used, since the moisture actually decreases the combustion heat. The relationship between the two heating values is given by Eq. 24.3, where M is the moisture content from a proximate analysis.

$$\mathrm{HV}_{\mathrm{as\ fired}} = \mathrm{HV}_{\mathrm{dry}}(1 - M) \qquad 24.3$$

Moisture in fuel is undesirable because it increases fuel weight (transportation costs) and decreases available combustion heat.[5]

7. ASH AND MINERAL MATTER

Mineral matter is the noncombustible material in a fuel. *Ash* is the residue remaining after combustion. Ash may contain some combustible carbon. The two terms ("mineral matter" and "ash") are often used interchangeably when reporting fuel analyses.

Ash may also be categorized according to where it is recovered. Dry and wet *bottom ashes* are recovered from *ash pits*. (As little as 10% of the total ash content may be recovered in the ash pit.) *Flyash* is carried out of the boiler by the flue gas. Flyash can be deposited on walls and heat transfer surfaces. It will be discharged from the stack if not captured. *Economizer ash* and *air heater ash* are recovered from the devices the ash is named after.

The finely powdered ash that covers combustion grates protects them from high temperatures.[6] If the ash has a low (i.e., below 2200°F; 1200°C) fusion temperature (melting point), it may form *clinkers* in the furnace and/or *slag* in other high-temperature areas. In extreme cases, it can adhere to the surfaces. Ashes with high melting (fusion) temperatures (i.e., above 2600°F; 1430°C) are known as *refractory ashes*. The T_{250} *temperature* is used as an index of slagging tendencies of an ash. This is the temperature at which the slag becomes molten with a viscosity of 250 poise. Slagging will be experienced when the T_{250} temperature is exceeded.

The actual melting point depends on the ash composition. Ash is primarily a mixture of silica (SiO_2), alumina (Al_2O_3), and ferric oxide (Fe_2O_3).[7] The relative proportions of each will determine the melting point, with lower melting points resulting from high amounts of ferric oxide and calcium oxide. The melting points of pure alumina and pure silica are in the 2700 to 2800°F (1480 to 1540°C) range.

Coal ash is either of a bituminous type or lignite type. Bituminous-type ash (from midwestern and eastern coals) contains more ferric oxide than lime and magnesia. Lignite-type ash (from western coals) contains more lime and magnesia than ferric oxide.

8. SULFUR

Several forms of sulfur are present in coal and fuel oils. *Pyritic sulfur* (FeS_2) is the primary form. *Organic sulfur* is combined with hydrogen and carbon in other compounds. *Sulfate sulfur* is iron sulfate and gypsum ($CaSO_4 \cdot 2H_2O$). Sulfur in elemental, organic, and pyritic forms oxidizes to sulfur dioxide. *Sulfur trioxide* can be formed under certain conditions. Sulfur trioxide combines with water to form sulfuric acid and is a major source of boiler/stack corrosion and pollution.

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

9. WOOD

Wood is not an industrial fuel, though it may be used in small quantities in developing countries. Most woods have heating values around 8300 Btu/lbm (19 MJ/kg), with specific values depending on the species and moisture content. Variations in wood properties are so great that generalized properties are meaningless.

[2]Both of these are different from the standard temperature and pressure used for scientific work. The standard temperature in that case is 32°F (0°C).

[3]This assumes that none of the oxygen is in the form of carbonates.

[4]The value of $^1/_8$ follows directly from the combustion reaction of hydrogen and oxygen.

[5]A moisture content up to 5% is reported to be beneficial in some mechanically fired boilers.

[6]Some boiler manufacturers rely on the thermal protection the ash provides. For example, coal burned in cyclone boilers should have a minimum ash content of 7% to cover and protect the cyclone barrel tubes. Boiler wear and ash carryover will increase with lower ash contents.

[7]Calcium oxide (CaO), magnesium oxide ("magnesia," MgO), titanium oxide ("titania," TiO_2), ferrous oxide (FeO), and alkalies (Na_2O and K_2O) may be present in smaller amounts.

10. WASTE FUELS

Waste fuels are increasingly being burned or incinerated in industrial boilers and furnaces. Such fuels include digester and landfill gases, waste process gases, flammable waste liquids, and volatile organic compounds (VOCs) such as benzene, toluene, xylene, ethanol, and methane. Other waste fuels include oil shale, tar sands, green wood, seed and rice hulls, biomass refuse, peat, tire shreddings, and shingle/roofing waste.

The term *refuse-derived fuels*, RDF, is used to describe fuel produced from municipal waste. After separation (removal of glass, plastics, metals, corrugated cardboard, etc.), the waste is merely pushed into the combustion chamber. If the waste is to be used elsewhere, it is compressed and baled.

The heating value of RDF depends on the moisture content and fraction of combustible material. For RDFs derived from typical municipal wastes, the heating value will range from 3000 to 6000 Btu/lbm (7 to 14 MJ/kg), though higher ranges (7500 to 8500 Btu/lbm (17.5 to 19.8 MJ/kg)) can be obtained by careful selection of ingredients. Pelletized RDF (containing some coal and a limestone binder) with heating values around 8000 Btu/lbm (18.6 MJ/kg) can be used as a supplemental fuel in coal-fired units.

Scrap tires are an attractive fuel source because of their high heating values—12,000 to 16,000 Btu/lbm (28 to 37 MJ/kg). To be compatible with existing coal-loading equipment, tires are chipped or shredded to 1-inch size (25 mm). Tires in this form are known as *tire-derived fuel*, TDF. Metal (from tire reinforcement) may or may not be present.

TDF has been shown capable of supplying up to 90% of a steam-generating plant's total Btu input without any deterioration in particulate emissions, pollutants, and stack opacity. In fact, compared with some low-quality coals (e.g., lignite), TDF is far superior: about 2.5 times the heating value and about 2.5 times less sulfur per Btu.

11. INCINERATION

Many toxic wastes are incinerated rather than "burned." Incineration and combustion are not the same. *Incineration* is the term used to describe a disposal process that uses combustion to render wastes ineffective (nonharmful, nontoxic, etc.). Wastes and combustible fuel are combined in a furnace, and the heat of combustion destroys the waste.[8] Wastes may themselves be combustible, though they may not be self-sustaining if the moisture content is too high.

Incinerated wastes are categorized into seven types. Type 0 is *trash* (highly combustible paper and wood, with 10% or less moisture); type 1 is *rubbish* (combustible waste with up to 25% moisture); type 2 is *refuse* (a mixture of rubbish and garbage, with up to 50% moisture); type 3 is *garbage* (residential waste with up to 70% moisture); type 4 is animal solids and pathological wastes (85% moisture); type 5 is industrial process wastes in gaseous, liquid, and semiliquid form; and type 6 is industrial process wastes in solid and semisolid form requiring incineration in hearth, retort, or grate burning equipment.

[8]Rotary kilns can accept waste in many forms. They are "workhorse" incinerators.

12. COAL

Coal consists of volatile matter, fixed carbon, moisture, noncombustible mineral matter ("ash"), and sulfur. *Volatile matter* is driven off as a vapor when the coal is heated, and it is directly related to flame size. *Fixed carbon* is the combustible portion of the solid remaining after the volatile matter is driven off. Moisture is present in the coal as free water and (for some mineral compounds) as water of hydration. Sulfur, an undesirable component, contributes to heat content.

Coals are categorized into anthracitic, bituminous, and lignitic types. *Anthracite coal* is clean, dense, and hard. It is comparatively difficult to ignite but burns uniformly and smokelessly with a short flame. *Bituminous coal* varies in composition, but generally has a higher volatile content than anthracite, starts easily, and burns freely with a long flame. Smoke and soot are possible if bituminous coal is improperly fired. *Lignite coal* is a coal of woody structure, very high in moisture and with a low heating value. It normally ignites slowly due to its moisture, breaks apart when burning, and burns with little smoke or soot.

Coal is burned efficiently in a particular furnace only if it is uniform in size. Screen sizes are used to grade coal, but descriptive terms can also be used.[9] *Run-of-mine coal*, ROM, is coal as mined. *Lump coal* is in the 1 to 6 in (25 to 150 mm) range. *Nut coal* is smaller, followed by even smaller *pea coal screenings*, and *fines* (dust).

13. LOW-SULFUR COAL

Switching to low-sulfur coal is one way of meeting strict sulfur emission standards. Western and eastern low-sulfur coals have different properties.[10,11] Eastern low-sulfur coals are generally low-impact coals (that is, few changes need to be made to the power plant when switching to them). Western coals are generally high-impact coals. Properties of typical high- and low-sulfur fuels are shown in Table 24.2.

[9]The problem with descriptive terms is that one company's "pea coal" may be as small as $\frac{1}{4}$ in (6 mm), while another's may start at $\frac{1}{2}$ in (13 mm).

[10]In the United States, low-sulfur coals predominately come from the western United States ("western subbituminous"), although some come from the east ("eastern bituminous").

[11]Some parameters affected by coal type are coal preparation, firing rate, ash volume and handling, slagging, corrosion rates, dust collection and suppression, and fire and explosion prevention.

The lower sulfur content results in less boiler corrosion. However, of all the coal variables, the different ash characteristics are the most significant with regard to the steam generator components. The slagging and fouling tendencies are prime concerns.

Table 24.2 *Typical Properties of High- and Low-Sulfur Coals*[a]

property	high-sulfur	low-sulfur eastern	low-sulfur western
higher heating value, Btu/lbm	10,500	13,400	8000
(MJ/kg)	(24.4)	(31.2)	(18.6)
moisture content, %	11.7	6.9	30.4

(°C)	(1320)	(1590)	(1590)

(Multiply Btu/lbm by 2.326 to obtain kJ/kg.)
[a]All properties are "as received."

14. CLEAN COAL TECHNOLOGIES

A lot of effort has been put into developing technologies that will reduce acid rain, pollution and air toxics (NO_x and SO_2), and global warming. These technologies are loosely labeled as *clean coal technologies*, CCTs. Whether or not these technologies can be retrofitted into an existing plant or designed into a new plant depends on the economics of the process.

With *coal cleaning*, coal is ground to ultrafine sizes to remove sulfur and ash-bearing minerals.[12] However, finely ground coal creates problems in handling, storage, and dust production. The risk of fire and explosion increases. Different approaches to reducing the problems associated with transporting and storing finely ground coal include the use of dust suppression chemicals, pelletizing, transportation of coal in liquid slurry form, and pelletizing followed by reslurrying. Some of these technologies may not be suitable for retrofit into existing installations.

With *coal upgrading*, moisture is thermally removed from low-rank coal (e.g., lignite or subbituminous coal). With some technologies, sulfur and ash are also removed when the coal is upgraded.

Reduction in sulfur dioxide emissions is the goal of *SO_2 control* technologies. These technologies include conventional use of lime and limestone in *flue gas desulfurization* (FGD) systems, *furnace sorbent-injection* (FSI) and *duct sorbent-injection*. *Advanced scrubbing* is included in FGD technologies.

Redesigned burners and injectors and adjustment of the flame zone are typical types of *NO_x control*. Use of secondary air, injection of ammonia or urea, and selective catalytic reduction (SCR) are also effective in NO_x reduction.

Fluidized-bed combustion (FBC) reduces NO_x emissions by reducing combustion temperatures to around 1500°F (815°C). FBC is also effective in removing up to 90% of the SO_2. *Atmospheric FBC* operates at atmospheric pressure, but higher thermal efficiencies are achieved in *pressurized FBC* units operating at pressures up to 10 atm.

Integrated gasification/combined cycle (IGCC) processes are able to remove 99% of all sulfur while reducing NO_x to well below current emission standards. *Synthetic gas* (syngas) is derived from coal. Syngas has a lower heating value than natural gas, but it can be used to drive gas turbines in combined cycles or as a reactant in the production of other liquid fuels.

15. COKE

Coke, typically used in blast furnaces, is produced by heating coal in the absence of oxygen. The heavy hydrocarbons crack (i.e., the hydrogen is driven off), leaving only a carbonaceous residue containing ash and sulfur. Coke burns smokelessly. *Breeze* is coke smaller than 5/8 in (16 mm). It is not suitable for use in blast furnaces, but steam boilers can be adapted to use it. *Char* is produced from coal in a 900°F (500°C) carbonization process. The volatile matter is removed, but there is little cracking. The process is used to solidify tars, bitumens, and some gases.

16. LIQUID FUELS

Liquid fuels are lighter hydrocarbon products refined from crude petroleum oil. They include liquefied petroleum gas (LPG), gasoline, kerosene, jet fuel, diesel fuels, and heating oils. Important characteristics of a liquid fuel are its composition, ignition temperature, flash point,[13] viscosity, and heating value.

17. FUEL OILS

In the United States, fuel oils are categorized into grades 1 through 6 according to their viscosities.[14] Viscosity is the major factor in determining firing rate and the need for preheating for pumping or atomizing prior to burning. Grades 1 and 2 can be easily pumped at ambient temperatures. In the United States, the heaviest fuel oil used is grade 6, also known as *Bunker C oil*.[15,16]

[12]80% or more of *micronized coal* is 44 microns or less in size.

[13]This is different from the *flash point* that is the temperature at which fuel oils generate enough vapor to sustain ignition in the presence of spark or flame.

[14]Grade 3 became obsolete in 1948. Grade 5 is also subdivided into light and heavy categories.

[15]120°F (48°C) is the optimum temperature for pumping no. 6 fuel oil. At that temperature, no. 6 oil has a viscosity of approximately 3000 SSU. Further heating is necessary to lower the viscosity to 150 to 350 SSU for atomizing.

[16]To avoid *coking* of oil, heating coils in contact with oil should not be hotter than 240°F (116°C).

Table 24.3 *Typical Properties of Common Commercial Fuels*

	butane	no. 1 diesel	no. 2 diesel	ethanol	gasoline	JP-4	methanol	propane
chemical formula	C_4H_{10}	–	–	C_2H_5OH	–	–	CH_3OH	C_3H_8

(Multiply Btu/lbm by 2.326 to obtain kJ/kg.)
(Multiply Btu/gal by 0.2786 to obtain MJ/m^3.)
[a]Specific gravities of propane and butane are with respect to air.

Fuel oils are also classified according to their viscosities as *distillate oils* (lighter) and *residual fuel oils* (heavier).

Like coal, fuel oils contain sulfur and ash that may cause pollution, slagging on the hot end of the boiler, and corrosion in the cold end. Table 24.4 lists typical properties of fuel oils.

Table 24.4 *Typical Properties of Fuel Oils*[a]

grade	specific gravity	heating value MBtu/gal[b]	heating value GJ/m^3
1	0.805	134	37.3
2	0.850	139	38.6
4	0.903	145	40.4
5	0.933	148	41.2
6	0.965	151	41.9

(Multiply MBtu/gal by 0.2786 to obtain GJ/m^3.)
[a]Actual values will vary depending on composition.
[b]One MBtu equals one thousand Btus.

18. GASOLINE

Gasoline is not a pure compound. It is a mixture of various hydrocarbons blended to give a desired flammability, volatility, heating value, and octane rating. There are numerous blends that can be used to produce gasoline.

Gasoline's heating value depends only slightly on composition. Within a variation of 1½%, the heating value can be taken as 20,200 Btu/lbm (47.0 MJ/kg) for regular gasoline and as 20,300 Btu/lbm (47.2 MJ/kg) for high-octane aviation fuel.

Since gasoline is a mixture of hydrocarbons, different fractions will evaporate at different temperatures. The *volatility* is the percentage of the fuel that has evaporated by a given temperature. Typical volatility specifications call for 10% at 167°F (75°C), 50% at 221°F (105°C), and 90% at 275°F (135°C). Low volatility causes difficulty in starting and poor engine performance at low temperatures.

The *octane number*, ON, is a measure of knock resistance. It is based on comparison, performed in a standardized one-cylinder engine, with the burning of isooctane and *n*-heptane. *N*-heptane, C_7H_{16}, is rated zero and produces violent knocking. Isooctane, C_8H_{18}, is rated 100 and produces relatively knock-free operation. The percentage blend by volume of these fuels that matches the performance of the gasoline is the octane rating. The *research octane number* (RON) is a measure of the fuel's antiknock characteristics while idling; the *motor octane number* (MON) applies to high-speed, high-acceleration operations. The octane rating reported for commercial gasoline is an average of the two.

The *performance number* (PN) of gasoline containing antiknock compounds (e.g., tetraethyl lead, TEL) is related to the octane number.

$$\text{ON} = 100 + \frac{\text{PN} - 100}{3} \qquad 24.4$$

19. OXYGENATED GASOLINE

In parts of the United States, gasoline is "oxygenated" during the cold winter months. The addition of *oxygenates* raises the combustion temperature, reducing carbon monoxide and unburned hydrocarbons.[17] Common oxygenates used in *reformulated gasoline* (RFG) include methyl tertiary-butyl ether (MTBE) and ethanol. Methanol, ethyl tertiary-butyl ether (ETBE) tertiary-amyl methyl ether (TAME) and tertiary-amyl ethyl ether (TAEE) may also be used. Oxygenates are added to bring the minimum oxygen level to 2 to 3% by weight.[18]

[17]Oxygenation may not be successful in reducing carbon dioxide. Since the heating value of the oxygenates is lower, fuel consumption of oxygenated fuels is higher. On a per-gallon (per-liter) basis, oxygenation reduces carbon dioxide. On a per-mile (per-kilometer) basis, however, oxygenation appears to increase carbon dioxide.
[18]Other specifications on gasoline during the winter months intended to reduce pollution may include maximum percentages of benzene and total aromatics, and limits on Reid vapor pressure.

Table 24.5 *Typical Properties of Common Oxygenates*

	MTBE[c]	TAME	ETBE	TAEE
specific gravity	0.744	0.740	0.770	0.791
octane	110	112	105	100
heating value (MBtu/gal)[a]	93.6			
Reid vapor pressure (psig)[b]	8	4	3	2
percent oxygen by weight	18.2	15.7	15.7	13.8
volumetric percent needed to achieve gasoline				
2.7% oxygen by weight	15.1	17.2	17.2	19.4
2.0% oxygen by weight	11.0	12.4	12.7	13.0

(Multiply MBtu/gal by 0.2786 to obtain MJ/m^3.)
[a]One MBtu equals one thousand Btus.
[b]The Reid vapor pressure is the vapor pressure when heated to 100°F (38°C).
[c]MTBE is water soluble and does not degrade. As a suspected carcinogen, it is proving to be a serious threat to water supplies.

20. DIESEL FUEL

Properties and specifications for various grades of diesel fuel oil are similar to specifications for fuel oils. Grade 1-D ("D" for diesel) is a light distillate oil for high-speed engines in service requiring frequent speed and load changes. Grade 2-D is a distillate of lower volatility for engines in industrial and heavy mobile service. Grade 4-D is for use in medium speed engines under sustained loads.

Diesel oils are specified by a *cetane number*, which is a measure of the ignition quality (ignition delay) of a fuel. Like the octane number for gasoline, the cetane number is determined by comparison with standard fuels. Cetane, $C_{16}H_{34}$, has a cetane number of 100. *N*-methyl-naphthalene, $C_{11}H_{10}$, has a cetane number of zero. A cetane number of approximately 30 is required for satisfactory operation of low-speed diesel engines. High-speed engines, such as those used in cars, require a cetane number of 45 or more. The cetane number can be increased by use of such additives as amyl nitrate, ethyl nitrate, and ether.

A diesel fuel's *pour point* number refers to its viscosity. A fuel with a pour point of 10°F (−12°C) will flow freely above that temperature. A fuel with a high pour point will thicken in cold temperatures.

The *cloud point* refers to the temperature at which wax crystals cloud the fuel at lower temperatures. The cloud point should be 20°F (−7°C) or higher. Below that temperature, the engine will not run well.

21. ALCOHOL

Both methanol and ethanol can be used in internal combustion engines. *Methanol* (*methyl alcohol*) is produced from natural gas and coal, although it can also be produced from wood and organic debris. *Ethanol* (*ethyl alcohol, grain alcohol*) is distilled from grain, sugar cane, potatoes, and other agricultural products containing various amounts of sugars, starches, and cellulose. Although methanol generally works as well as ethanol, only ethanol can be produced in large quantities from inexpensive agricultural products and by-products.

Alcohol is water soluble. The concentration of alcohol is measured by its *proof*, where 200 proof is pure alcohol. (180 proof is 90% alcohol and 10% water.)

Gasohol is a mixture of approximately 90% gasoline and 10% alcohol (generally ethanol).[19] Alcohol's heating value is less than gasoline's, so fuel consumption (per distance traveled) is higher with gasohol. Also, since alcohol absorbs moisture more readily than gasoline, corrosion of fuel tanks becomes problematic. In some engines, significantly higher percentages of alcohol may require such modifications as including larger carburetor jets, timing advances, heaters for preheating fuel in cold weather, tank lining to prevent rusting, and alcohol-resistant gaskets.

Mixtures of gasoline and alcohol can be designated by the first letter and the fraction of the alcohol. E10 is a mixture of 10% ethanol in gasoline. M85 is a blend of 85% methanol and 15% gasoline.

Alcohol is a poor substitute for diesel fuel because alcohol's cetane number is low—from −20 to +8. Straight injection of alcohol results in poor performance and heavy knocking.

22. GASEOUS FUELS

Various gaseous fuels are used as energy sources, but most applications are limited to natural gas and *liquefied petroleum gases*, LPGs (i.e., propane, butane, and mixtures of the two).[20,21] Natural gas is a mixture of methane (55 to 95%), higher hydrocarbons

[19]In fact, oxygenated gasoline may use more than 10% alcohol.
[20]A number of *manufactured gases* are of practical (and historical) interest in specific industries, including *coke-oven gas, blast-furnace gas, water gas, producer gas,* and *town gas.* However, these gases are not now in widespread use.
[21]At atmospheric pressure, propane boils at −40°F (−40°C), while butane boils at 32°F (0°C).

(primarily ethane), and other noncombustible gases. Typical heating values for natural gas range from 950 to 1100 Btu/ft^3 (35 to 41 MJ/m^3).

The production of *synthetic gas (syngas)* through coal gasification may be applicable to large power generating plants. The cost of gasification, though justifiable to reduce sulfur and other pollutants, is too high for syngas to become a widespread substitute for natural gas.

23. IGNITION TEMPERATURE

The *ignition temperature* (*autoignition temperature*) is the minimum temperature at which combustion can be sustained. It is the temperature at which more heat is generated by the combustion reaction than is lost to the surroundings, after which combustion becomes self-sustaining. For coal, the minimum ignition temperature varies from around 800°F (425°C) for bituminous varieties to 900 to 1100°F (480 to 590°C) for anthracite. For sulfur and charcoal, the ignition temperatures are approximately 470°F (240°C) and 650°F (340°C), respectively.

For gaseous fuels, the ignition temperature depends on the air/fuel ratio, temperature, pressure, and length of time the source of heat is applied. Ignition can be instantaneous or with a lag, depending on the temperature. Generalizations can be made for any gas, but the generalized temperatures will be meaningless without specifying all of these factors.

24. ATMOSPHERIC AIR

It is important to make a distinction between "air" and "oxygen." Atmospheric air is a mixture of oxygen, nitrogen, and small amounts of carbon dioxide, water vapor, argon, and other inert ("rare") gases. For the purpose of combustion calculations, all constituents except oxygen are grouped with nitrogen. It is necessary to supply 4.32 (i.e., 1/0.2315) masses of air to obtain one mass of oxygen. Similarly, it is necessary to supply 4.773 volumes of air to obtain one volume of oxygen. The average molecular weight of air is 28.97. The specific gas constant is 53.35 ft-lbf/lbm-°R (287 kJ/kg·K).

Table 24.6 *Composition of Dry Air* [a]

component	percent by weight	percent by volume
oxygen	23.15	20.95
nitrogen/inerts	76.85	79.05
ratio of nitrogen to oxygen	3.320	3.773[b]
ratio of air to oxygen	4.320	4.773

[a] Inert gases and CO_2 included as N_2.
[b] The value is also reported by various sources as 3.76, 3.78, and 3.784.

25. COMBUSTION REACTIONS

A limited number of elements appear in combustion reactions. Carbon, hydrogen, sulfur, hydrocarbons, and oxygen are the reactants. Carbon dioxide and water vapor are the main products, with carbon monoxide, sulfur dioxide, and sulfur trioxide occurring in lesser amounts. Nitrogen and excess oxygen emerge essentially unchanged from the stack.

Combustion reactions occur according to the normal chemical reaction principles. Balancing combustion reactions is usually easiest if carbon is balanced first, followed by hydrogen and then oxygen. When a gaseous fuel has several combustible gases, the volumetric fuel composition can be used as coefficients in the chemical equation.

Table 24.7 lists ideal combustion reactions. These reactions do not include any nitrogen or water vapor that are present in the combustion air.

Example 24.1

A gaseous fuel is 20% hydrogen and 80% methane by volume. What volume of oxygen is required to burn 120 volumes of fuel at the same conditions?

Solution

Write the unbalanced combustion reaction.

$$H_2 + CH_4 + O_2 \longrightarrow CO_2 + H_2O$$

Use the volumetric analysis as coefficients of the fuel.

$$0.2H_2 + 0.8CH_4 + O_2 \longrightarrow CO_2 + H_2O$$

Balance the carbons.

$$0.2H_2 + 0.8CH_4 + O_2 \longrightarrow 0.8CO_2 + H_2O$$

Balance the hydrogens.

$$0.2H_2 + 0.8CH_4 + O_2 \longrightarrow 0.8CO_2 + 1.8H_2O$$

Balance the oxygens.

$$0.2H_2 + 0.8CH_4 + 1.7O_2 \longrightarrow 0.8CO_2 + 1.8H_2O$$

For gaseous components, the coefficients correspond to the volumes. Since one (0.2 + 0.8) volume of fuel requires 1.7 volumes of oxygen, the required oxygen is

$$(1.7)(120 \text{ volumes of fuel}) = 204 \text{ volumes of oxygen}$$

Table 24.7 *Ideal Combustion Reactions*

fuel	formula	reaction equation (excluding nitrogen)
carbon (to CO)	C	$2C + O_2 \longrightarrow 2CO$
carbon (to CO_2)	C	$2C + 2O_2 \longrightarrow 2CO_2$
sulfur (to SO_2)	S	$S + O_2 \longrightarrow SO_2$
sulfur (to SO_3)	S	$2S + 3O_2 \longrightarrow 2SO_3$
carbon monoxide	CO	$2CO + O_2 \longrightarrow 2CO_2$
methane	CH_4	$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$
acetylene	C_2H_2	$2C_2H_2 + 5O_2 \longrightarrow 4CO_2 + 2H_2O$
ethylene	C_2H_4	$C_2H_4 + 3O_2 \longrightarrow 2CO_2 + 2H_2O$
ethane	C_2H_6	$2C_2H_6 + 7O_2 \longrightarrow 4CO_2 + 6H_2O$
hydrogen	H_2	$2H_2 + O_2 \longrightarrow 2H_2O$
hydrogen sulfide	H_2S	$2H_2S + 3O_2 \longrightarrow 2H_2O + 2SO_2$
propane	C_3H_8	$C_3H_8 + 5O_2 \longrightarrow 3CO_2 + 4H_2O$
n-butane	C_4H_{10}	$2C_4H_{10} + 13O_2 \longrightarrow 8CO_2 + 10H_2O$
octane	C_8H_{18}	$2C_8H_{18} + 25O_2 \longrightarrow 16CO_2 + 18H_2O$
olefin series	C_nH_{2n}	$2C_nH_{2n} + 3nO_2 \longrightarrow 2nCO_2 + 2nH_2O$
paraffin series	C_nH_{2n+2}	$2C_nH_{2n+2} + (3n+1)O_2 \longrightarrow 2nCO_2 + (2n+2)H_2O$

(Multiply oxygen volumes by 3.773 to get nitrogen volumes.)

26. STOICHIOMETRIC REACTIONS

Stoichiometric quantities (*ideal quantities*) are the exact quantities of reactants that are needed to complete a combustion reaction with no reactants left over. Table 24.7 contains some of the more common chemical reactions. Stoichiometric volumes and masses can always be determined from the balanced chemical reaction equation. Table 24.8 can be used to quickly determine stoichiometric amounts for some fuels.

27. STOICHIOMETRIC AIR

Stoichiometric air (*ideal air*) is the air necessary to provide the exact amount of oxygen for complete combustion of a fuel. Stoichiometric air includes atmospheric nitrogen. For each volume of oxygen, 3.773 volumes of nitrogen pass unchanged through the reaction.[22]

[22]The only major change in the nitrogen gas is its increase in temperature. Dissociation of nitrogen and formation of nitrogen compounds can occur but are essentially insignificant.

Stoichiometric air can be stated in units of mass (pounds or kilograms of air) for solid and liquid fuels, and in units of volume (cubic feet or cubic meters of air) for gaseous fuels. When stated in terms of mass, the stoichiometric ratio of air to fuel masses is known as the ideal *air/fuel ratio*, $R_{a/f}$.

$$R_{a/f,\text{ideal}} = \frac{m_{\text{air,ideal}}}{m_{\text{fuel}}} \qquad 24.5$$

The ideal air/fuel ratio can always be determined from the combustion reaction equation. It can also be determined by adding the oxygen and nitrogen amounts from Table 24.8.

For fuels whose ultimate analysis is known, the approximate stoichiometric air (oxygen and nitrogen) requirement in pounds of air per pound of fuel (kilograms of air per kilogram of fuel) can be quickly calculated from Eq. 24.6.[23] All oxygen in the fuel is assumed to be free moisture. All of the reported oxygen is assumed to be locked up in the form of water. Any free oxygen (i.e., oxygen dissolved in liquid fuels) is subtracted from the oxygen requirements.

$$R_{a/f,\text{ideal}} = (34.5)\left(\frac{G_C}{3} + G_H - \frac{G_O}{8} + \frac{G_S}{8}\right) \quad \text{[solid fuels]} \qquad 24.6$$

For fuels consisting of a mixture of gases, Eq. 24.7 and the constants J_i from Table 24.9 can be used to quickly determine the stoichiometric air requirements.

$$R_{a/f,\text{ideal}} = \sum J_i G_i \quad \text{[gaseous fuels]} \qquad 24.7$$

For fuels consisting of a mixture of gases, the air/fuel ratio can also be expressed in volumes of air per volume of fuel.

$$\text{volumetric air/fuel ratio} = \sum K_i B_i \quad \text{[gaseous fuels]} \qquad 24.8$$

[23]This is a "compromise" equation. Variations in the atomic weights will affect the coefficients slightly. The coefficient 34.5 is reported as 34.43 in some older books. 34.5 is the exact value needed for carbon and hydrogen, which constitute the bulk of the fuel. 34.43 is the correct value for sulfur, but the error is small and is disregarded in this equation.

Table 24.8 *Consolidated Combustion Data*[a,b,c,d]

for 1 mole of fuel						for 1 ft^3 of fuel[e]				for 1 lbm of fuel					
	air		other products			air		other products		air		other products

(Multiply lbm/ft^3 by 0.06243 to obtain kg/m^3.)

[a]Rounding of molecular weights and air composition may introduce slight inconsistencies in the table values. This table is based on atomic weights with at least four significant digits, a ratio of 3.773 volumes of nitrogen per volume of oxygen, and 379.5 ft^3 per mole at 1 atm and 60°F.

[b]Volumes per unit mass are at 1 atm and 60°F (16°C). To obtain volumes at other temperatures, multiply by (T°F + 460)/520 or (T°C + 283)/289.

[c]The volume of water applies only when the combustion products are at such high temperatures that all of the water is in vapor form.

[d]This table can be used to directly determine some SI ratios. For kg/kg ratios, the values are the same as lbm/lbm. For L/L or m^3/m^3, use ft^3/ft^3. For mol/mol, use mole/mole. For mixed units (e.g., ft^3/lbm), conversions are required.

[e]Sulfur is not used in gaseous form.

Table 24.9 *Approximate Air/Fuel Ratio Coefficients for Components of Natural Gas*[a]

fuel component	J (gravimetric)	K (volumetric)
acetylene, C_2H_2	13.25	11.945
butane, C_4H_{10}	15.43	31.06
carbon monoxide, CO	2.463	2.389
ethane, C_2H_6	16.06	16.723
ethylene, C_2H_4	14.76	14.33
hydrogen, H_2	34.23	2.389
hydrogen sulfide, H_2S	6.074	7.167
methane, CH_4	17.20	9.556
oxygen, O_2	−4.320	−4.773
propane, C_3H_8	15.65	23.89

[a]Rounding of molecular weights and air composition may introduce slight inconsistencies in the table values. This table is based on atomic weights with at least four significant digits and a ratio of 3.773 volumes of nitrogen per volume of oxygen.

Example 24.2

Use Table 24.8 to determine the theoretical volume of 90°F (32°C) air required to burn 1 volume of 60°F (16°C) carbon monoxide to carbon dioxide.

Solution

From Table 24.8, 0.5 volumes of oxygen are required to burn 1 volume of carbon monoxide to carbon dioxide. 1.887 volumes of nitrogen accompany the oxygen. The total amount of air at the temperature of the fuel is 0.5 + 1.887 = 2.387 volumes.

This volume will expand at the higher temperature. The volume at the higher temperature is

$$\frac{(90°\text{F} + 460)(2.387 \text{ volumes})}{60°\text{F} + 460} = 2.53 \text{ volumes}$$

Example 24.3

How much air is required for the ideal combustion of (a) coal with an ultimate analysis of 93.5% carbon, 2.6% hydrogen, 2.3% oxygen, 0.9% nitrogen, and 0.7% sulfur, (b) fuel oil with a gravimetric analysis of 84% carbon, 15.3% hydrogen, 0.4% nitrogen, and 0.3% sulfur, and (c) natural gas with a volumetric analysis of 86.92% methane, 7.95% ethane, 2.81% nitrogen, 2.16% propane, and 0.16% butane?

Solution

(a) Use Eq. 24.6.

$$\begin{aligned} R_{a/f,\text{ideal}} &= (34.5)\left(\frac{G_C}{3} + G_H - \frac{G_O}{8} + \frac{G_S}{8}\right) \\ &= (34.5)\left(\frac{0.935}{3} + 0.026 - \frac{0.023}{8} + \frac{0.007}{8}\right) \\ &= 11.58 \text{ lbm/lbm (kg/kg)} \end{aligned}$$

(b) Use Eq. 24.6.

$$\begin{aligned} R_{a/f,\text{ideal}} &= (34.5)\left(\frac{G_C}{3} + G_H + \frac{G_S}{8}\right) \\ &= (34.5)\left(\frac{0.84}{3} + 0.153 + \frac{0.003}{8}\right) \\ &= 14.95 \text{ lbm/lbm (kg/kg)} \end{aligned}$$

(c) Use Eq. 24.8 and the coefficients from Table 24.9.

$$\begin{aligned} \text{volumetric air/fuel ratio} &= \sum K_i B_i \\ &= (0.8692)(9.556) + (0.0795)(16.723) \\ &\quad + (0.0216)(23.89) + (0.0016)(31.06) \\ &= 10.20 \text{ ft}^3/\text{ft}^3 \text{ (m}^3/\text{m}^3) \end{aligned}$$

28. INCOMPLETE COMBUSTION

Incomplete combustion occurs when there is insufficient oxygen to burn all of the hydrogen, carbon, and sulfur in the fuel. Without enough available oxygen, carbon burns to carbon monoxide.[24] Carbon monoxide in the flue gas indicates incomplete and inefficient combustion. Incomplete combustion is caused by cold furnaces, low combustion temperatures, poor air supply, smothering from improperly vented stacks, and insufficient mixing of air and fuel.

29. FLUE GAS ANALYSIS

Combustion products that pass through a furnace's exhaust system are known as *flue gases* (*stack gases*). Flue gases are almost all nitrogen.[25] (Nitrogen oxides are not present in large enough amounts to be included separately in combustion reactions.)

The actual composition of flue gases can be obtained in a number of ways, including by electronic detectors, less expensive "length-of-stain" detectors, and direct sampling with an Orsat apparatus.

The *Orsat apparatus* determines the volumetric percentages of CO_2, CO, O_2, and N_2 in a flue gas. The sampled flue gas passes through a series of chemical compounds. The first compound absorbs only CO_2, the next only O_2, and the third only CO. The unabsorbed gas is assumed to be N_2 and is found by subtracting the volumetric percentages of all other components from 100%. An Orsat analysis is a dry analysis; the percentage of water vapor is not usually determined. A wet volumetric analysis (needed to compute the dew-point temperature) can be derived if the volume of water vapor is added to the Orsat volumes.

[24]Toxic alcohols, ketones, and aldehydes may also be formed during incomplete combustion.

[25]This assumption is helpful in making quick determinations of the thermodynamic properties of flue gases.

Modern electronic detectors can determine free oxygen (and other gases) independently of the other gases. Because the relationship between oxygen and excess air is relatively insensitive to fuel composition, oxygen measurements are replacing standard carbon dioxide measurements in determining combustion efficiency.

30. ACTUAL AND EXCESS AIR

Complete combustion occurs when all of the fuel is burned. Usually, *excess air* is required to achieve complete combustion. Excess air is expressed as a percentage of the theoretical air requirements. Different fuel types burn more efficiently with different amounts of excess air. Coal-fired boilers need approximately 30 to 35% excess air, oil-based units need about 15%, and natural gas burners need about 10%.

The actual air/fuel ratio for dry, solid fuels with no unburned carbon can be estimated from the flue gas analysis and the fraction of carbon in the fuel.

$$R_{a/f,\text{actual}} = \frac{m_{\text{air,actual}}}{m_{\text{fuel}}} = \frac{3.04B_{N_2}\left(G_C + \frac{G_S}{1.833}\right)}{B_{CO_2} + B_{CO}} \quad [24.9]$$

Too much free oxygen or too little carbon dioxide in the flue gas is indicative of excess air. The relationship between excess air and oxygen in the flue gases is not highly affected by fuel composition.[26] The relationship between excess air and the volumetric fraction of oxygen in the flue gas is given in Table 24.10.

Reducing the air/fuel ratio will have several results. (a) The furnace temperature will increase due to a reduction in cooling air. (b) The flue gas will decrease in quantity. (c) The heat loss will decrease. (d) The furnace efficiency will increase. (e) Pollutants will (usually) decrease.

With a properly adjusted furnace and good mixing, the flue gas will contain no carbon monoxide, and the amount of carbon dioxide will be maximized. The stoichiometric amount of carbon dioxide in the flue gas is known as the *ultimate CO_2*. The air/fuel mixture should be adjusted until the maximum level of carbon dioxide is attained.

Table 24.10 *Approximate Volumetric Percentage of Oxygen in Stack Gas*

	excess air							
fuel[a]	0%	1%	5%	10%	20%	50%	100%	200%
fuel oils, no. 2–6	0	0.22	1.06	2.02	3.69	7.29	10.8	14.2
natural gas	0	0.25	1.18	2.23	4.04	7.83	11.4	14.7
propane	0	0.23	1.08	2.06	3.75	7.38	10.9	14.3

[a]Values for coal are only marginally lower than the values for fuel oils.

[26]The relationship between excess air and CO_2 is much more dependent on fuel type and composition.

Example 24.4

Propane (C_3H_8) is burned completely with 20% excess air. What is the volumetric fraction of carbon dioxide in the flue gas?

Solution

The balanced chemical reaction equation is

$$C_3H_8 + 5O_2 \longrightarrow 3CO_2 + 4H_2O$$

With 20% excess air, the oxygen volume is $(1.2)(5) = 6$.

$$C_3H_8 + 6O_2 \longrightarrow 3CO_2 + 4H_2O + O_2$$

From Table 24.6, there are 3.773 volumes of nitrogen for every volume of oxygen.

$$(6)(3.773) = 22.6$$

$$C_3H_8 + 6O_2 + 22.6N_2 \longrightarrow 3CO_2 + 4H_2O + O_2 + 22.6N_2$$

For gases, the coefficients can be interpreted as volumes. The volumetric fraction of carbon dioxide is

$$B_{CO_2} = \frac{3}{3+4+1+22.6} = 0.0980\ (9.8\%)$$

31. CALCULATIONS BASED ON FLUE GAS ANALYSIS

Equation 24.10 gives the approximate percentage (by volume) of actual excess air.

$$\text{actual excess air, \% by volume} = \frac{(100\%)(B_{O_2} - 0.5B_{CO})}{0.264B_{N_2} - B_{O_2} + 0.5B_{CO}} \quad [24.10]$$

The ultimate CO_2 (i.e., the maximum theoretical carbon dioxide) can be determined from Eq. 24.11.

$$\text{ultimate } CO_2\text{, \% by volume} = \frac{(100\%)B_{CO_2,\text{actual}}}{1 - 4.773B_{O_2,\text{actual}}} \quad [24.11]$$

The mass ratio of dry flue gases to solid fuel is given by Eq. 24.12.

$$\frac{\text{mass of flue gas}}{\text{mass of solid fuel}} = \frac{\left(11B_{CO_2} + 8B_{O_2} + 7(B_{CO} + B_{N_2})\right)\left(G_C + \frac{G_S}{1.833}\right)}{3(B_{CO_2} + B_{CO})} \quad [24.12]$$

Example 24.5

A coal has a proximate analysis of 75% carbon. The volumetric analysis of the flue gas is 80.2% nitrogen, 12.6% carbon dioxide, 6.2% oxygen, and 1.0% carbon monoxide. Find the (a) actual air/fuel ratio, (b) percentage excess air, (c) ultimate carbon dioxide, and (d) mass of flue gas per mass of fuel.

Solution

(a) Use Eq. 24.9.

$$R_{a/f,\text{actual}} = \frac{3.04B_{N_2}G_C}{B_{CO_2} + B_{CO}}$$

$$= \frac{(3.04)(0.802)(0.75)}{0.126 + 0.01}$$

$$= 13.4 \text{ lbm air/lbm fuel (kg air/kg fuel)}$$

(b) Use Eq. 24.10.

$$\text{actual excess air} = \frac{(100\%)(B_{O_2} - 0.5B_{CO})}{0.264B_{N_2} - B_{O_2} + 0.5B_{CO}}$$

$$= \frac{(100\%)\big((0.062 - (0.5)(0.01)\big)}{(0.264)(0.802) - 0.062 + (0.5)(0.01)}$$

$$= 36.8\% \text{ by volume}$$

(c) Use Eq. 24.11.

$$\text{ultimate } CO_2 = \frac{(100\%)B_{CO_2,\text{actual}}}{1 - 4.773B_{O_2,\text{actual}}}$$

$$= \frac{(100\%)(0.126)}{1 - (4.773)(0.062)}$$

$$= 17.9\% \text{ by volume}$$

(d) Use Eq. 24.12.

$$\frac{\text{mass of flue gas}}{\text{mass of solid fuel}} = \frac{\begin{pmatrix}11B_{CO_2} + 8B_{O_2} \\ +7(B_{CO} + B_{N_2})\end{pmatrix}\left(G_C + \frac{G_S}{1.833}\right)}{3(B_{CO_2} + B_{CO})}$$

$$= \frac{\begin{pmatrix}((11)(0.126) + (8)(0.062) \\ +(7)(0.01 + 0.802)\end{pmatrix}(0.75)}{(3)(0.126 + 0.01)}$$

$$= 13.9 \text{ lbm flue gas/lbm fuel (kg flue gas/kg fuel)}$$

32. TEMPERATURE OF FLUE GAS

The temperature of the gas at the furnace outlet—before the gas reaches any other equipment—should be approximately 550°F (300°C). Overly low temperatures mean there is too much excess air. Overly high temperatures—above 750°F (400°C)—mean that heat is being wasted to the atmosphere and indicate other problems (ineffective heat transfer surfaces, overfiring, defective combustion chamber, etc.).

The *net stack temperature* is the difference between the stack and local environment temperatures. The net stack temperature should be as low as possible without causing corrosion of the low end.

33. SMOKE

The amount of smoke can be used as an indicator of combustion cleanliness. Smoky combustion may indicate improper air/fuel ratio, insufficient draft, leaks, insufficient preheat, or misadjustment of the fuel system.

Smoke measurements are made in a variety of ways, with the standards depending on the equipment used. Photoelectric sensors in the stack may be used to continuously monitor smoke. The *smoke spot number* (SSN) and ASTM smoke scale are used with continuous stack monitors. For coal-fired furnaces, the maximum desirable smoke number is SSN 4. For grade 2 fuel oil, the SSN should be less than 1; for grade 4, SSN 4; for grades 5L, 5H, and low-sulfur residual fuels, SSN 3; for grade 6, SSN 4.

The *Ringelman scale* is a subjective method in which the smoke density is visually compared to five standardized white-black grids. Ringelman chart no. 0 is solid white; chart no. 5 is solid black. Ringelman chart no. 1, which is 20% black, is the preferred operating point for most power plants.

34. DEW POINT OF FLUE GAS MOISTURE

The *dew point* is the temperature at which the water vapor in the flue gas begins to condense in a constant pressure process. To avoid condensation and corrosion in the stack, the temperature of the flue gases must be above the dew point.

Dalton's law predicts the dew point of moisture in the flue gas. The partial pressure of the water vapor depends on the mole fraction (i.e., the volumetric fraction) of water vapor. The higher the water vapor pressure, the higher the dew point. Air entering a furnace can also contribute to moisture in the flue gas. This moisture should be added to the water vapor from combustion when calculating the mole fraction.

$$\text{partial pressure} = (\text{water vapor mole fraction}) \times (\text{flue gas pressure}) \qquad 24.13$$

Once the water vapor's partial pressure is known, the dew point can be found from steam tables as the saturation temperature corresponding to the partial pressure.

When there is no sulfur in the fuel, the dew point is typically around 100°F (40°C). The presence of sulfur in virtually any quantity increases the actual dew point to approximately 300°F (150°C).[27]

[27]The theoretical dew point is even higher—up to 350 to 400°F (175 to 200°C). For complex reasons, the theoretical value is not attained.

35. HEAT OF COMBUSTION

The *heating value* of a fuel can be determined experimentally in a *bomb calorimeter*, or it can be estimated from the fuel's chemical analysis. The *higher heating value*, HHV (or *gross heating value*), of a fuel includes the heat of vaporization (condensation) of the water vapor formed from hydrogen during combustion. The *lower heating value*, LHV (or *net heating value*), assumes that all the products of combustion remain gaseous. The LHV is generally the value to use in calculations of thermal energy generated, since the heat of vaporization is not recovered in the stack system.

Traditionally, heating values have been reported on an HHV basis for coal-fired systems but on an LHV basis for natural gas-fired combustion turbines. There is an 11% difference between HHV and LHV thermal efficiencies for gas-fired systems and a 4% difference for coal-fired systems, approximately.

The HHV can be calculated from the LHV if the enthalpy of vaporization, h_{fg}, is known at the pressure of the water vapor.[28] In Eq. 24.14, m_{water} is the mass of water produced per unit (lbm, mole, m^3, etc.) of fuel.

$$\text{HHV} = \text{LHV} + m_{\text{water}} h_{fg} \qquad 24.14$$

Only the hydrogen that is not locked up with oxygen in the form of water is combustible. This is known as the *available hydrogen*. The correct percentage of combustible hydrogen, $G_{\text{H,available}}$, is calculated from the hydrogen and oxygen fraction. Equation 24.15 assumes that all of the oxygen is present in the form of water.

$$G_{\text{H,available}} = G_{\text{H,total}} - \frac{G_{\text{O}}}{8} \qquad 24.15$$

Dulong's formula calculates the higher heating value of coals and coke with a 2 to 3% accuracy for moisture contents below approximately 10%.[29] The gravimetric or volumetric analysis percentages for each combustible element (including sulfur) are multiplied by the heating value per unit (mass or volume) from App. 24.A and summed.

$$\text{HHV}_{\text{MJ/kg}} = 32.78 G_{\text{C}} + 141.8 \left(G_{\text{H}} - \frac{G_{\text{O}}}{8} \right) + 9.264 G_{\text{S}}$$

[SI] 24.16(a)

$$\text{HHV}_{\text{Btu/lbm}} = 14{,}093 G_{\text{C}} + 60{,}958 \left(G_{\text{H}} - \frac{G_{\text{O}}}{8} \right) + 3983 G_{\text{S}}$$

[U.S.] 24.16(b)

[28]For the purpose of initial studies, the heat of vaporization is usually assumed to be 1040 Btu/lbm (2.42 kJ/kg). This corresponds to a partial pressure of approximately 1 psia (7 kPa) and a dew point of 100°F (38°C).

[29]The coefficients in Eq. 24.16 are slightly different from the coefficients originally proposed by Dulong. Equation 24.16 reflects currently accepted heating values that were unavailable when Dulong developed his formula. Equation 24.16 makes the following assumptions: (1) None of the oxygen is in carbonate form. (2) There is no free oxygen. (3) The hydrogen and carbon are not combined as hydrocarbons. (4) Carbon is amorphous, not graphitic. (5) Sulfur is not in sulfate form. (6) Sulfur burns to sulfur dioxide.

The higher heating value of gasoline can be approximated from the Baumé specific gravity.

$$\text{HHV}_{\text{gasoline,MJ/kg}} = 42.61 + 0.093(^\circ\text{Baumé} - 10)$$

[SI] 24.17(a)

$$\text{HHV}_{\text{gasoline,Btu/lbm}} = 18{,}320 + 40(^\circ\text{Baumé} - 10)$$

[U.S.] 24.17(b)

The heating value of petroleum oils (including diesel fuel) can also be approximately determined from the oil's specific gravity. The values derived from Eq. 24.18 may not exactly agree with values for specific oils because the equation does not account for refining methods and sulfur content. Equation 24.18 was originally intended for combustion at constant volume, as in a gasoline engine. However, variations in heating values for different oils are very small, and Eq. 24.18 is widely used as an approximation for all types of combustion, including constant pressure combustion in industrial boilers.

$$\text{HHV}_{\text{fuel oil,MJ/kg}} = 51.92 - 8.792(\text{SG})^2$$

[SI] 24.18(a)

$$\text{HHV}_{\text{fuel oil,Btu/lbm}} = 22{,}320 - 3780(\text{SG})^2$$

[U.S.] 24.18(b)

Example 24.6

A coal has an ultimate analysis of 93.9% carbon, 2.1% hydrogen, 2.3% oxygen, 0.3% nitrogen, and 1.4% ash. What are its (a) higher and (b) lower heating values in Btu/lbm?

Solution

(a) The noncombustible ash, oxygen, and nitrogen do not contribute to heating value. Some of the hydrogen is in the form of water. From Eq. 24.2, the available hydrogen is

$$G_{\text{H,available}} = G_{\text{H,total}} - \frac{G_{\text{O}}}{8}$$

$$= 2.1\% - \frac{2.3\%}{8} = 1.8\%$$

From App. 24.A, the higher heating values of carbon and hydrogen are 14,093 Btu/lbm and 60,958 Btu/lbm, respectively. From Eq. 24.16, the total heating value per pound of coal is

$$\text{HHV} = (0.939) \left(14{,}093 \frac{\text{Btu}}{\text{lbm}} \right) + (0.018) \left(60{,}958 \frac{\text{Btu}}{\text{lbm}} \right)$$

$$= 14{,}331 \text{ Btu/lbm}$$

(b) All of the combustible hydrogen forms water vapor. The mass of water produced is equal to the hydrogen mass plus eight times as much oxygen.

$$\begin{aligned} m_{\text{water}} &= m_{\text{H,available}} + m_{\text{oxygen}} \\ &= 0.018 + (8)(0.018) \\ &= 0.162 \text{ lbm water/lbm coal} \end{aligned}$$

Assume that the partial pressure of the water vapor is approximately 1 psia (7 kPa). Then, from steam tables, the heat of condensation will be 1040 Btu/lbm. From Eq. 24.14, the lower heating value is approximately

$$\begin{aligned} \text{LHV} &= \text{HHV} - m_{\text{water}} h_{fg} \\ &= 14{,}331 \frac{\text{Btu}}{\text{lbm}} - \left(0.162 \frac{\text{lbm}}{\text{lbm}}\right)\left(1040 \frac{\text{Btu}}{\text{lbm}}\right) \\ &= 14{,}163 \text{ Btu/lbm} \end{aligned}$$

Alternatively, the lower heating value of the coal can be calculated from Eq. 24.16 by substituting the lower (net) hydrogen heating value from App. 24.A, 51,623 Btu/lbm, for the gross heating value of 60,598 Btu/lbm. This yields 14,160 Btu/lbm.

36. MAXIMUM THEORETICAL COMBUSTION (FLAME) TEMPERATURE

It can be assumed that the maximum theoretical increase in flue gas temperature will occur if all of the combustion energy is absorbed adiabatically by the combustion products. This provides a method of estimating the *maximum theoretical combustion temperature*, also sometimes called the *maximum flame temperature* or *adiabatic flame temperature*.[30]

In Eq. 24.19, the mass of the products is the sum of the fuel, oxygen, and nitrogen masses for stoichiometric combustion. The mean specific heat is a gravimetrically weighted average of the values of c_p for all combustion gases. (Since nitrogen comprises the majority of the combustion gases, the mixture's specific heat will be approximately that of nitrogen.) The heat of combustion can be found either from the lower heating value, LHV, or from a difference in air enthalpies across the furnace.

$$T_{\max} = T_i + \frac{\text{lower heat of combustion}}{m_{\text{products}} c_{p,\text{mean}}} \qquad 24.19$$

Actual flame temperatures are always lower than the theoretical temperature. Most fuels produce flame temperatures in the range of 3350 to 3800°F (1850 to 2100°C).

37. COMBUSTION LOSSES

A portion of the combustion energy is lost in heating the dry flue gases, dfg.[31] This is known as *dry flue gas loss*. In Eq. 24.20, $m_{\text{flue gas}}$ is the mass of dry flue gas per pound of fuel. It can be estimated from Eq. 24.9. Although the full temperature difference is used, the specific heat should be evaluated at the average temperature of the flue gas. For quick estimates, the dry flue gas can be assumed to be pure nitrogen.

$$q_1 = m_{\text{flue gas}} c_p (T_{\text{flue gas}} - T_{\text{incoming air}}) \qquad 24.20$$

Heat is lost in the vapor formed during the combustion of hydrogen. In Eq. 24.21, m_{vapor} is the mass of vapor per pound of fuel. G_{H} is the gravimetric fraction of hydrogen in the fuel. h_g is the enthalpy of superheated steam at the flue gas temperature and the partial pressure of the water vapor. h_f is the enthalpy of saturated liquid at the air's entrance temperature.

$$q_2 = m_{\text{vapor}}(h_g - h_f) = 8.94 G_{\text{H}}(h_g - h_f) \qquad 24.21$$

Heat is lost when it is absorbed by moisture originally in the combustion air (and by free moisture in the fuel, if any). In Eq. 24.22, $m_{\text{combustion air}}$ is the mass of combustion air per pound of fuel. ω is the humidity ratio. h'_g is the enthalpy of superheated steam at the air's entrance temperature and partial pressure of the water vapor.

$$\begin{aligned} q_3 &= m_{\text{atmospheric water vapor}}(h_g - h'_g) \\ &= \omega m_{\text{combustion air}}(h_g - h'_g) \end{aligned} \qquad 24.22$$

When carbon monoxide appears in the flue gas, potential energy is lost in incomplete combustion. The difference in the two heating values in Eq. 24.23 is 9746 Btu/lbm (24.67 MJ/kg).[32]

$$q_4 = \frac{(\text{HHV}_{\text{C}} - \text{HHV}_{\text{CO}}) G_{\text{C}} B_{\text{CO}}}{B_{\text{CO}_2} + B_{\text{CO}}} \qquad 24.23$$

For solid fuels, potential energy is lost in unburned carbon in the ash. (Some carbon may be carried away in the flue gas, as well.) This is known as *combustible loss* or *unburned fuel loss*. In Eq. 24.24, m_{ash} is the mass of ash produced per pound of fuel consumed. $G_{\text{C,ash}}$ is the gravimetric fraction of carbon in the ash. The heating value of carbon is 14,093 Btu/lbm (32.8 MJ/kg).

$$q_5 = \text{HHV}_{\text{C}} m_{\text{ash}} G_{\text{C,ash}} \qquad 24.24$$

Energy is also lost through radiation from boiler surfaces. This can be calculated if enough information is known. The *radiation loss* is fairly insensitive to different firing rates, and once calculated it can be considered constant for different conditions.

Other conditions where energy can be lost include air leaks, poor pulverizer operation, excessive blowdown, steam leaks, missing or loose insulation, and excessive soot-blower operation. Losses due to these sources must be evaluated on a case-by-case basis.

[30] Flame temperature is limited by the dissociation of common reaction products (CO_2, N_2, etc.). At high enough temperatures (3400 to 3800°F; 1880 to 2090°C), the endothermic dissociation process reabsorbs combustion heat and the temperature stops increasing. The temperature at which this occurs is known as the *maximum flame temperature*. This definition of flame temperature is not a function of heating values and flow rates.

[31] The abbreviation "dfg" for dry flue gas is peculiar to the combustion industry. It may not be recognized outside of that field.

[32] Obsolete values of 10,150 Btu/lbm (23.61 MJ/kg) and 10,190 Btu/lbm (23.70 MJ/kg) are still encountered for the difference in heating values between carbon and carbon monoxide.

38. COMBUSTION EFFICIENCY

The *combustion efficiency* (also referred to as *boiler efficiency, furnace efficiency,* and *thermal efficiency*) is the overall thermal efficiency of the combustion reaction. Coal and fuel oil furnaces with air heaters and economizers have 75 to 85% efficiencies. Gas furnaces have 75 to 80% efficiencies.

In Eq. 24.25, m_{steam} is the mass of steam produced per pound of fuel burned. The useful heat may also be determined from the boiler rating. One *boiler horsepower* is equal to approximately 33,475 Btu/hr (9.808 kW).[33]

$$\eta = \frac{\text{useful heat extracted}}{\text{heating value}} = \frac{m_{\text{steam}}(h_{\text{steam}} - h_{\text{feedwater}})}{\text{HHV}} \qquad 24.25$$

Calculating the efficiency by subtracting all known losses is known as the *loss method.* Minor sources of thermal energy such as the entering air and feedwater are essentially disregarded.

$$\eta = \frac{\text{HHV} - q_1 - q_2 - q_3 - q_4 - q_5 - \text{radiation}}{\text{HHV}} \qquad 24.26$$

Combustion efficiency can be improved by decreasing either the temperature or the volume of the flue gas or both. Since the latent heat of moisture is a loss, and since the amount of moisture generated corresponds to the hydrogen content of the fuel, a minimum efficiency loss due to moisture formation cannot be eliminated. This minimum loss is approximately 13% for natural gas, 8% for oil, and 6% for coal.

PRACTICE PROBLEMS

1. Methane (MW = 16.043) with a higher heating value of 24,000 Btu/lbm (55.8 MJ/kg) is burned in a furnace with a 50% efficiency based on the higher heating value. How much water can be heated from 60 to 200°F (15 to 95°C) when 7 ft^3 (200 L) at 60°F and 14.73 psia are burned?

(A) 25 lbm (11 kg)
(B) 35 lbm (16 kg)
(C) 50 lbm (23 kg)
(D) 95 lbm (43 kg)

The answer is (A).

2. 15 lbm/hr (6.8 kg/h) of propane (C_3H_8, MW = 44.097) are burned stoichiometrically in air. What volume of dry carbon dioxide (CO_2) is formed after cooling to 70°F (21°C) and 14.7 psia (101 kPa)?

(A) 180 ft^3/hr (5.0 m^3/h)
(B) 270 ft^3/hr (7.6 m^3/h)
(C) 390 ft^3/hr (11 m^3/h)
(D) 450 ft^3/hr (13 m^3/h)

The answer is (C).

3. In a particular installation, 30% excess air at 15 psia (103 kPa) and 100°F (40°C) is needed for the combustion of methane. How much nitrogen (MW = 28.016) passes through the furnace if methane at the same conditions is burned at the rate of 4000 ft^3/hr (31 L/s)?

(A) 270 lbm/hr (0.33 kg/s)
(B) 930 lbm/hr (0.11 kg/s)
(C) 1800 lbm/hr (0.22 kg/s)
(D) 2700 lbm/hr (0.34 kg/s)

The answer is (D).

4. Propane (C_3H_8) is burned with 20% excess air. What is the gravimetric percentage of carbon dioxide in the flue gas?

(A) 8%
(B) 12%
(C) 15%
(D) 22%

The answer is (C).

5. (*Time limit: one hour*) A natural gas is 93% methbreak ane, 3.73% nitrogen, 1.82% hydrogen, 0.45% carbon monoxide, 0.35% oxygen, 0.25% ethylene, 0.22% carbon dioxide, and 0.18% hydrogen sulfide by volume. The gas is burned with 40% excess air. Atmospheric air is 60°F and at standard atmospheric pressure.

(a) What is the gas density?

(A) 0.017 lbm/ft^3
(B) 0.043 lbm/ft^3
(C) 0.069 lbm/ft^3
(D) 0.110 lbm/ft^3

The answer is (B).

(b) What are the theoretical air requirements?

(A) 5 ft^3 air/ft^3 fuel
(B) 7 ft^3 air/ft^3 fuel
(C) 9 ft^3 air/ft^3 fuel
(D) 13 ft^3 air/ft^3 fuel

The answer is (C).

[33]Boiler horsepower is sometimes equated with a gross heating rate of 44,633 Btu/hr (13.08 kW). However, this is the total incoming heating value assuming a standardized 75% combustion efficiency.

(c) What is the percentage of CO_2 in the flue gas (wet basis)?

(A) 6.9%
(B) 7.7%
(C) 8.1%
(D) 11%

The answer is (A).

(d) What is the percentage of CO_2 in the flue gas (dry basis)?

(A) 6.9%
(B) 7.7%
(C) 8.1%
(D) 11%

The answer is (C).

6. (*Time limit: one hour*) A utility boiler burns coal with an ultimate analysis of 76.56% carbon, 7.7% oxygen, 6.1% silicon, 5.5% hydrogen, 2.44% sulfur, and 1.7% nitrogen. 410 lbm/hr of refuse are removed with a composition of 30% carbon and 0% sulfur. All the sulfur and the remaining carbon is burned. The power plant has the following characteristics.

- coal feed rate: 15,300 lbm/hr
- electric power rating: 17 MW
- generator efficiency: 95%
- steam generator efficiency: 86%
- cooling water rate: 225 ft^3/sec

(a) What is the emission rate of solid particulates in lbm/hr?

(A) 23 lbm/hr
(B) 150 lbm/hr
(C) 810 lbm/hr
(D) 1700 lbm/hr

The answer is (D).

(b) How much sulfur dioxide is produced per hour?

(A) 220 lbm/hr
(B) 340 lbm/hr
(C) 750 lbm/hr
(D) 1100 lbm/hr

The answer is (C).

(c) What is the temperature rise of the cooling water?

(A) 2.4°F
(B) 6.5°C
(C) 9.8°F
(D) 13°F

The answer is (A).

(d) What efficiency must the flue gas particulate collectors have in order to meet a limit of 0.1 lbm of particulates per million Btu per hour (0.155 kg/MW)?

(A) 93.1%
(B) 97.4%
(C) 98.8%
(D) 99.1%

The answer is (C).

Nomenclature

Ca	calcium	mg/L $CaCO_3$
H	total hardness	mg/L $CaCO_3$
L	free lime	mg/L $CaCO_3$
M	alkalinity	mg/L $CaCO_3$
N	normality	gEW/L
O	hydroxides	mg/L $CaCO_3$
P	phenolphthalein alkalinity	mg/L $CaCO_3$
S	sulfate	mg/L $CaCO_3$
T	total alkalinity	mg/L $CaCO_3$
V	volume	mL

1. CATIONS AND ANIONS IN NEUTRAL SOLUTIONS

Equivalency concepts provide a useful check on the accuracy of water analyses. For the water to be electrically neutral, the sum of anion equivalents must equal the sum of cation equivalents.

Concentrations of dissolved compounds in water are usually expressed in mg/L, not equivalents. However, anionic and cationic substances can be converted to their equivalent concentrations in milliequivalents per liter (meq/L) by dividing their concentrations in mg/L by their equivalent weights.

Example 25.1

A water analysis reveals the following ionic components in solution. Verify that the analysis is reasonably accurate.

Solution

Use the equivalent weights in App. 22.C to complete the following table.

compound	concentration (mg/L)	equivalent weight	meq/L
cations			
Ca^{++}	29.0	20.0	1.45
Mg^{++}	16.4	12.2	1.34
Na^{+}	23.0	23.0	1.00
K^{+}	17.5	39.1	0.45
			total 4.24
anions			
HCO_3^-	171	61.0	2.81
SO_4^{--}	36.0	48.0	0.75
Cl^-	24.0	35.5	0.68
			total 4.24

The sums of the cation equivalents and anion equivalents are equal. The analysis is presumed to be reasonably accurate.

2. ACIDITY

Acidity is a measure of acids in solution. Acidity in surface water is caused by formation of carbonic acid (H_2CO_3) from carbon dioxide in the air (Eq. 25.1). Carbonic acid is aggressive and must be neutralized to eliminate a cause of water pipe corrosion. If the pH of water is greater than 4.5, carbonic acid ionizes to form bicarbonate (Eq. 25.2). If the pH is greater than 8.3, carbonate ions form (Eq. 25.3).

$$CO_2 + H_2O \rightarrow H_2CO_3 \qquad 25.1$$

$$H_2CO_3 + H_2O \rightarrow HCO_3^- + H_3O^+ \quad (pH > 4.5) \qquad 25.2$$

$$HCO_3^- + H_2O \rightarrow CO_3^{--} + H_3O^+ \quad (pH > 8.3) \qquad 25.3$$

Measurement of acidity is done by titration with a standard basic measuring solution. Acidity in water is typically given in terms of the $CaCO_3$ equivalent that would neutralize the acid. The constant 50,000 in Eq. 25.4 is the product of the equivalent weight of $CaCO_3$ (50 g) and 1000 mg/g.

$$\text{acidity (mg/L of } CaCO_3) = \frac{(V_{\text{titrant,mL}})(N_{\text{titrant}})(50{,}000)}{V_{\text{sample,mL}}} \qquad 25.4$$

The standard titration procedure for determining acidity measures the amount of titrant needed to raise the pH to 3.7 plus the amount needed to raise the pH to 8.3. The total of these two is used in Eq. 25.4. Most water samples, unless grossly polluted with industrial wastes, will exist at a pH greater than 3.7, so the titration will be a one-step process.

3. ALKALINITY

Alkalinity is a measure of the ability of a water to neutralize acids (i.e., to absorb hydrogen ions without significant pH change). The principal alkaline ions are OH^-, CO_3^{--}, and HCO_3^-. Other radicals, such as NO_3^-, also contribute to alkalinity, but their presence is rare. The measure of alkalinity is the sum of concentrations of each of the substances measured as equivalent $CaCO_3$.

The standard titration method for determining alkalinity measures the amount of acidic titrant needed to lower the pH to 8.3 plus the amount needed to lower the pH to 4.5. Therefore, alkalinity is the sum of all titratable base concentrations down to a pH of 4.5. The constant 50,000 in Eq. 25.5 is the product of the equivalent weight of $CaCO_3$ (50 g) and 1000 mg/g.

$$M \text{ (mg/L of } CaCO_3) = \frac{(V_{\text{titrant,mL}})(N_{\text{titrant}})(50{,}000)}{V_{\text{sample,mL}}} \qquad 25.5$$

Example 25.2

Water from a city well is analyzed and found to contain 20 mg/L as substance of HCO_3^- and 40 mg/L as substance of CO_3^{--}. What is the alkalinity of the water?

Solution

From App. 22.C, the equivalent weight of HCO_3^- is 61 g/mol, the equivalent weight of CO_3^{--} is 30 g/mol, and the equivalent weight of $CaCO_3$ is 50 g/mol.

Use Eq. 25.5.

$$M \text{ (mg/L of } CaCO_3) = \left(20 \frac{\text{mg}}{\text{L}}\right)\left(\frac{50 \frac{\text{g}}{\text{mol}}}{61 \frac{\text{g}}{\text{mol}}}\right) + \left(40 \frac{\text{mg}}{\text{L}}\right)\left(\frac{50 \frac{\text{g}}{\text{mol}}}{30 \frac{\text{g}}{\text{mol}}}\right)$$
$$= 83.1 \text{ mg/L as } CaCO_3$$

4. INDICATOR SOLUTIONS

End points for acidity and alkalinity titrations are determined by color changes in indicator dyes that are pH sensitive. Several commonly used indicators are listed in Table 25.1.

Table 25.1 *Indicator Solutions Commonly Used in Water Chemistry*

indicator	titration	end point pH	color change
bromophenol blue	acidity	3.7	yellow to blue
phenolphthalein	acidity	8.3	colorless to red-violet
phenolphthalein	alkalinity	8.3	red-violet to colorless
mixed bromocresol/ green-methyl red	alkalinity	4.5	grayish to orange-red

Depending on pH, alkaline samples can contain hydroxide alone, hydroxide and carbonate, carbonate alone, carbonate and bicarbonate, or bicarbonate alone. Samples containing hydroxide or hydroxide and carbonate have a high pH, usually greater than 10. If the titration is complete at the phenolphthalein end point (i.e., the mixed bromocresol green-methyl red indicator does not change color), the alkalinity is hydroxide alone. Samples containing carbonate and bicarbonate alkalinity have a pH greater than 8.3, and the titration to the phenolphthalein end point represents stoichiometrically one-half of the carbonate alkalinity. If the volume of phenolphthalein titrant equals the volume of titrant needed to reach the mixed bromocresol green-methyl red end point, all of the alkalinity is in the form of carbonate.

If abbreviations of P for the measured phenolphthalein alkalinity and M for the total alkalinity are used, the following relationships define the possible alkalinity states of the sample. In sequence, the relationships can be used to determine the actual state of a sample.

(state I)	hydroxide $= P = M$
(state II)	hydroxide $= 2P - M$ and carbonate $= 2(M - P)$
(state III)	carbonate $= 2P = M$
(state IV)	carbonate $= 2P$ and bicarbonate $= M - 2P$
(state V)	bicarbonate $= M$

Example 25.3

A 100 mL sample is titrated for alkalinity by using 0.02 N sulfuric acid solution. To reach the phenolphthalein end point requires 3.0 mL of the acid solution, and an additional 12.0 mL is added to reach the mixed bromocresol green-methyl red end point. Calculate the (a) phenolphthalein alkalinity and (b) total alkalinity. (c) What are the ionic forms of alkalinity present?

Solution

(a) Use Eq. 25.5.

$$P = \frac{(V_{\text{titrant,mL}})(N_{\text{titrant}})(50{,}000)}{V_{\text{sample,mL}}}$$

$$= \frac{(3.0\text{ mL})\left(0.02\ \frac{\text{gEW}}{\text{L}}\right)\left(50{,}000\ \frac{\text{mg}}{\text{gEW}}\right)}{100\text{ mL}}$$

$$= 30\text{ mg/L (as } CaCO_3\text{)}$$

(b) Use Eq. 25.5.

$$M = \frac{(V_{\text{titrant,mL}})(N_{\text{titrant}})(50{,}000)}{V_{\text{sample,mL}}}$$

$$= \frac{(3.0\text{ mL} + 12.0\text{ mL}) \times \left(0.02\ \frac{\text{gEW}}{\text{L}}\right)\left(50{,}000\ \frac{\text{mg}}{\text{gEW}}\right)}{100\text{ mL}}$$

$$= 150\text{ mg/L (as } CaCO_3\text{)}$$

(c) Test the state relationships in sequence.

(I) hydroxide $= P = M$:

$30\text{ mg/L} \neq 150\text{ mg/L}$

(invalid: $P \neq M$)

(II) hydroxide $= 2P - M$:

$$(2)\left(30\ \frac{\text{mg}}{\text{L}}\right) - 150\ \frac{\text{mg}}{\text{L}}$$

$$= 60\ \frac{\text{mg}}{\text{L}} - 150\ \frac{\text{mg}}{\text{L}} = -90\text{ mg/L}$$

(invalid: negative value)

(III) carbonate $= 2P = M$:

$$(2)\left(30\ \frac{\text{mg}}{\text{L}}\right) \neq 150\text{ mg/L}$$

(invalid: $2P \neq M$)

(IV) carbonate $= 2P$:

$$(2)\left(30\ \frac{\text{mg}}{\text{L}}\right) = 60\text{ mg/L}$$

bicarbonate $= M - 2P$:

$$150\ \frac{\text{mg}}{\text{L}} - (2)\left(30\ \frac{\text{mg}}{\text{L}}\right) = 90\text{ mg/L}$$

The process ends at (IV) since a valid answer is obtained. It is not necessary to check relationship (V), as (IV) gives consistent results. The alkalinity is composed of 60 mg/L as $CaCO_3$ of carbonate and 90 mg/L as $CaCO_3$ of bicarbonate.

5. HARDNESS

Hardness in natural water is caused by the presence of any polyvalent (but not singly charged) metallic cations. Principal cations causing hardness in water and the major anions associated with them are presented in Table 25.2. Because the most prevalent of these species are the divalent cations of calcium and magnesium, total hardness is typically defined as the sum of the concentration of these two elements and is expressed in terms of milligrams per liter as $CaCO_3$. (Hardness is occasionally expressed in units of *grains per gallon*, where 7000 grains are equal to a pound.)

Carbonate hardness is caused by cations from the dissolution of calcium or magnesium carbonate and bicarbonate in the water. Carbonate hardness is hardness that is chemically equivalent to alkalinity, where most of the alkalinity in natural water is caused by the bicarbonate and carbonate ions.

Noncarbonate hardness is caused by cations from calcium and magnesium compounds of sulfate, chloride, or silicate that are dissolved in the water. Noncarbonate hardness is equal to the total hardness minus the carbonate hardness.

Table 25.2 *Principal Cations and Anions Indicating Hardness*

cations	anions
Ca^{++}	HCO_3^-
Mg^{++}	SO_4^{--}
Sr^{++}	Cl^-
Fe^{++}	NO_3^-
Mn^{++}	SiO_3^{--}

Hardness can be classified as shown in Table 25.3. Although high values of hardness do not present a health risk, they have an impact on the aesthetic acceptability of water for domestic use. (Hardness reacts with soap to reduce its cleansing effectiveness and to form scum on the water surface.) Where feasible, carbonate hardness in potable water should be reduced to the 25 to 40 mg/L range and total hardness reduced to the 50 to 75 mg/L range.

Table 25.3 *Relationship of Hardness Concentration to Classification*

hardness (mg/L as $CaCO_3$)	classification
0 to 60	soft
61 to 120	moderately hard
121 to 180	hard
181 to 350	very hard
> 350	saline; brackish

Water containing bicarbonate (HCO_3^-) can be heated to precipitate carbonate (CO_3^{--}) as a scale. Water used in steam-producing equipment (e.g., boilers) must be essentially hardness-free to avoid deposit of scale.

$$Ca^{++} + 2HCO_3^- + \text{heat} \rightarrow CaCO_3 \downarrow + CO_2 + H_2O \quad 25.6$$

$$Mg^{++} + 2HCO_3^- + \text{heat} \rightarrow MgCO_3 \downarrow + CO_2 + H_2O \quad 25.7$$

Noncarbonate hardness, also called *permanent hardness*, cannot be removed by heating. It can be removed by precipitation softening processes (typically the lime-soda ash process) or by ion exchange processes using resins selective for ions causing hardness.

Hardness is measured in the laboratory by titrating the sample using a standardized solution of ethylenediaminetetraacetic acid (EDTA) and an indicator dye such as Eriochrome Black T. The sample is titrated at a pH of approximately 10 until the dye color changes from red to blue. The standardized solution of EDTA is usually prepared such that 1 mL of EDTA is equivalent to 1 mg/L of hardness, but Eq. 25.8 can be used to determine hardness with any strength EDTA solution.

$$H \text{ (as mg/L } CaCO_3) = \frac{V_{\text{titrant,mL}}(CaCO_3 \text{ equivalent of EDTA})(1000)}{V_{\text{sample,mL}}} \quad 25.8$$

Example 25.4

A water sample is found to contain sodium (Na^+, 15 mg/L), magnesium (Mg^{++}, 70 mg/L), and calcium (Ca^{++}, 40 mg/L). What is the hardness?

Solution

Sodium is singly charged, so it does not contribute to hardness. The necessary approximate equivalent weights are found in App. 22.C.

Mg: 12.2 g/mol

Ca: 20.0 g/mol

$CaCO_3$: 50 g/mol

The equivalent hardness is

$$H = \left(70 \frac{\text{mg}}{\text{L}}\right)\left(\frac{50 \frac{\text{g}}{\text{mol}}}{12.2 \frac{\text{g}}{\text{mol}}}\right) + \left(40 \frac{\text{mg}}{\text{L}}\right)\left(\frac{50 \frac{\text{g}}{\text{mol}}}{20 \frac{\text{g}}{\text{mol}}}\right)$$

$$= 387 \text{ mg/L as } CaCO_3$$

Example 25.5

A 75 mL water sample was titrated using 8.1 mL of an EDTA solution formulated such that 1 mL of EDTA is equivalent to 0.8 mg/L of $CaCO_3$. What is the hardness of the sample, measured in terms of mg/L of $CaCO_3$?

Solution

Use Eq. 25.8.

$$H = \frac{V_{\text{titrant,mL}}(CaCO_3 \text{ equivalent of EDTA})(1000)}{V_{\text{sample,mL}}}$$

$$= \frac{(8.1 \text{ mL})\left(0.8 \frac{\text{gEW}}{\text{L}}\right)\left(1000 \frac{\text{mg}}{\text{gEW}}\right)}{75 \text{ mL}}$$

$$= 86.4 \text{ mg/L as } CaCO_3$$

6. HARDNESS AND ALKALINITY

Hardness is caused by multi-positive ions. Alkalinity is caused by negative ions. Both positive and negative ions are present simultaneously. Therefore, an alkaline water can also be hard.

With some assumptions and minimal information about the water composition, it is possible to determine the ions in the water from the hardness and alkalinity. For example, Fe^{++} is an unlikely ion in most water supplies, and it is often neglected. Figure 25.1 can be used to quickly deduce the compounds in the water from hardness and alkalinity.

If hardness and alkalinity (both as $CaCO_3$) are the same, then there are no SO_4^{--}, Cl^-, or NO_3^- ions present. That is, there is no noncarbonate (permanent) hardness. If hardness is greater than the alkalinity, however, then noncarbonate hardness is present, and the carbonate (temporary) hardness is equal to the alkalinity. If hardness is less than the alkalinity, then all hardness is carbonate hardness, and the extra HCO_3^- comes from other sources (such as $NaHCO_3$).

Example 25.6

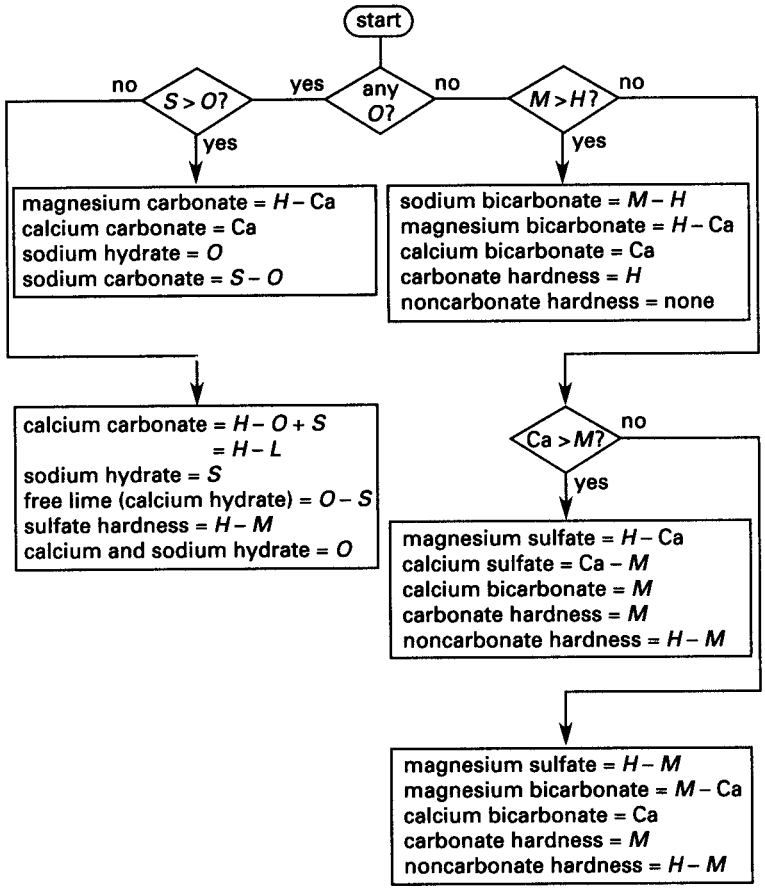
An analysis of a sample of water results in the following: alkalinity, 220 mg/L; hardness, 180 mg/L; Ca^{++}, 140 mg/L; OH^-, insignificant. All concentrations are expressed as $CaCO_3$. (a) What is the noncarbonate hardness? (b) What is the Mg^{++} content in mg/L as substance?

Solution

(a) Use Fig. 25.1 with $M > H$ (alkalinity greater than hardness).

$$[NaHCO_3] = M - H = 220 \frac{\text{mg}}{\text{L}} - 180 \frac{\text{mg}}{\text{L}}$$

$$= 40 \text{ mg/L as } CaCO_3$$



$$[Mg(HCO_3)_2] = H - Ca = 180 \frac{\text{mg}}{\text{L}} - 140 \frac{\text{mg}}{\text{L}}$$

$$= 40 \text{ mg/L as } CaCO_3$$

$$Ca(HCO_3)_2 = Ca = 140 \text{ mg/L as } CaCO_3$$

$$\text{carbonate hardness} = H = 180 \text{ mg/L as } CaCO_3$$

$$\text{noncarbonate hardness} = 0$$

[a]Refer to the chapter nomenclature.
[b]All concentrations are expressed as $CaCO_3$.

Figure 25.1 *Hardness and Alkalinity*[a,b]

(b) The Mg^{++} ion content as $CaCO_3$ is equal to the $Mg(HCO_3)_2$ content as $CaCO_3$. Use App. 22.C to convert $CaCO_3$ equivalents to amounts as substance. The factor that converts Mg^{++} as $CaCO_3$ to Mg^{++} as substance is 4.1.

$$Mg^{++} = \frac{40\ \frac{mg}{L}}{4.1} = 9.8\ mg/L\ as\ substance$$

7. NATIONAL PRIMARY DRINKING WATER STANDARDS

Following passage of the Safe Drinking Water Act in the United States, the Environmental Protection Agency (EPA) established minimum primary drinking water standards. These standards set limits on the amount of various substances in drinking water. Every public water supply serving at least 15 service connections or 25 or more people must ensure that its water meets these minimum standards.

Accordingly, the EPA has established the National Primary Drinking Water Standards and the National Secondary Drinking Water Standards. The primary standards establish *maximum contaminant levels* (MCL) and *maximum contaminant level goals* (MCLG) for materials that are known or suspected health hazards. The MCL is the enforceable level that the water supplier must not exceed, while the MCLG is an unenforceable health goal equal to the maximum level of a contaminant that is not expected to cause any adverse health effects over a lifetime of exposure.

8. NATIONAL SECONDARY DRINKING WATER STANDARDS

The national secondary drinking water standards are not designed to protect public health. Instead, they are intended to protect "public welfare" by providing helpful guidelines regarding the taste, odor, color, and other aesthetic aspects of drinking water.

Table 25.4 *National Primary Drinking Water Standards*[a]

contaminant	MCLG (mg/L)	MCL (mg/L)	potential health effect

[b]threshold odor number

9. IRON

Even at low concentrations, iron is objectionable because it stains porcelain bathroom fixtures, causes a brown color in laundered clothing, and can be tasted. Typically, iron is a problem in groundwater pumped from anaerobic aquifers in contact with iron compounds. Soluble ferrous ions can be formed under these conditions, which, when exposed to atmospheric air at the surface or to dissolved oxygen in the water system, are oxidized to the insoluble ferric state, causing the color and staining problems mentioned. Iron determinations are made through colorimetric analysis.

10. MANGANESE

Manganese ions are similar in formation, effect, and measurement to iron ions.

11. FLUORIDE

Natural fluoride is found in groundwaters as a result of dissolution from geologic formations. Surface waters generally contain much smaller concentrations of fluoride. An absence or low concentration of ingested fluoride causes the formation of tooth enamel less resistant to decay, resulting in a high incidence of dental cavities in children's teeth. Excessive concentration of fluoride causes *fluorosis*, a brownish discoloration of dental enamel. The MCL of 4.0 mg/L established by the EPA is to prevent unsightly fluorosis.

Communities with water supplies deficient in natural fluoride chemically add fluoride during the treatment process. Since water consumption is influenced by climate, the recommended optimum concentrations listed in Table 25.6 are based on the annual average of the maximum air temperatures based on a minimum of 5 years of records.

Compounds commonly used as fluoride sources in water treatment are listed in Table 25.7.

Table 25.6 *Recommended Optimum Concentrations of Fluoride in Drinking Water*

average air temperature range (°F)	recommended optimum concentration (mg/L)
53.7 and below	1.2
53.8 to 58.3	1.1
58.4 to 63.8	1.0
63.9 to 70.6	0.9
70.7 to 79.2	0.8
79.3 to 90.5	0.7

Table 25.7 *Fluoridation Chemicals*

compound	formula	percentage F^- ion (%)
sodium fluoride	NaF	45
sodium silicofluoride	Na_2SiF_6	61
hydrofluosilicic acid	H_2SiF_6	79
ammonium silicofluoride[a]	$(NH_4)_2SiF_6$	64

[a]used in conjunction with chlorine disinfection where it is desired to maintain a chloramine residual in the distribution system.

Example 25.7

A liquid feeder adds a 4.0% saturated sodium fluoride solution to a water supply, increasing the fluoride concentration from the natural fluoride level of 0.4 mg/L to 1.0 mg/L. The commercial NaF powder used to prepare the NaF solution contains 45% fluoride by weight. (a) How many pounds (kilograms) of NaF are required per million gallons (liters) treated? (b) What volume of 4% NaF solution is used per million gallons (liters)?

SI Solution

(a) $$m_{NaF} = \frac{1.0\ \frac{mg}{L} - 0.4\ \frac{mg}{L}}{0.45}$$
$$= 1.33\ kg/ML \quad \text{(kg per million liters)}$$

(b) A 4% NaF solution contains 40 000 mg NaF per liter.

$$\left(40\,000\ \frac{\text{mg}}{\text{L}}\right)(0.45) = 18\,000\ \text{mg/L}$$

$$V = \frac{\left(1.0 \times 10^6\ \frac{\text{L}}{\text{ML}}\right) \times \left(1.0\ \frac{\text{mg}}{\text{L}} - 0.4\ \frac{\text{mg}}{\text{L}}\right)}{18\,000\ \frac{\text{mg}}{\text{L}}}$$

$$= 33.3\ \text{L/ML}$$

Customary U.S. Solution

$$\text{(a)}\quad m_{\text{NaF}} = \left(\frac{1.0\ \frac{\text{mg}}{\text{L}} - 0.4\ \frac{\text{mg}}{\text{L}}}{0.45}\right)\left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right)$$

$$= 11.1\ \text{lbm/MG}\quad \text{(lbm per million gallons)}$$

(b) A 4% NaF solution contains 40,000 mg NaF per liter.

$$\left(40{,}000\ \frac{\text{mg}}{\text{L}}\right)(0.45) = 18{,}000\ \text{mg/L}$$

$$V = \frac{\left(1.0 \times 10^6\ \frac{\text{gal}}{\text{MG}}\right) \times \left(1.0\ \frac{\text{mg}}{\text{L}} - 0.4\ \frac{\text{mg}}{\text{L}}\right)}{18{,}000\ \frac{\text{mg}}{\text{L}}}$$

$$= 33.3\ \text{gal/MG}$$

12. PHOSPHOROUS

Phosphate content is more of a concern in wastewater treatment than in supply water, although phosphorus can enter water supplies in large amounts from runoff. Excessive phosphate discharge contributes to aquatic plant (phytoplankton, algae, and macrophytes) growth and subsequent *eutrophication.* (Eutrophication is an "over-fertilization" of receiving waters.)

Phosphorous is of considerable interest in the management of lakes and reservoirs because phosphorous is a nutrient that has a major effect on aquatic plant growth. Algae normally have a phosphorous content of 0.1 to 1% of dry weight. The molar N:P ratio for ideal algae growth is 16:1.

Phosphorus exists in several forms in aquatic environments. Soluble phosphorus occurs as *orthophosphate,* as condensed *polyphosphates* (from detergents), and as various organic species. Orthophosphates ($H_2PO_4^-$, HPO_4^{--}, and PO_4^{---}) and polyphosphates (such as $Na_3(PO_3)_6$) result from the use of synthetic detergents (*syndets*). A sizable fraction of the soluble phosphorous is in the organic form, originating from the decay or excretion of nucleic acids and algal storage products. Particulate phosphorus occurs in the organic form as a part of living organisms and detritus as well as in the inorganic form of minerals such as apatite.

Phosphorous is normally measured by colorimetric or digestion methods. The results are reported in terms of mg/L of phosphorous (e.g., "mg/L of P" or "mg/L of total P"), although the tests actually measure the concentration of orthophosphate. The concentration of a particular compound is found by multiplying the concentration as P by the molecular weight of the compound and dividing by the atomic weight of phosphorous (30.97).

A substantial amount of the phosphorus that enters lakes is probably not available to aquatic plants. Bioavailable species include orthophosphates, polyphosphates, most soluble organic phosphorus, and a portion of the particulate fraction. Studies have indicated that bioavailable phosphorous generally does not exceed 60% of the total phosphorous.

In aquatic systems, phosphorus does not enter into any redox reactions, nor are any common species volatile. Therefore, lakes retain a significant portion of the entering phosphorus. The main mechanism for retaining phosphorus is simple sedimentation of particles containing the phosphorous. Particulate phosphorus can originate from the watershed (*allochthonous material*) or can be formed within the lake (*autochthonous material*).

Much of the phosphorus that enters a lake is recycled, and a large fraction of the recycling occurs at the sediment-water interface. Recycling of phosphorus is linked to iron and manganese recycling. Soluble phosphorus in the water column is removed by adsorption onto iron and manganese hydroxides, which precipitate under aerobic conditions. However, when the *hypolimnion* (i.e., the lower part of the lake that is essentially stagnant) becomes anaerobic, the iron (or manganese) is reduced, freeing up phosphorus. This is consistent with a fairly general observation that phosphorous release rates are nearly an order of magnitude higher under anaerobic conditions than under aerobic conditions.

Factors that control phosphorus recycling rates are not well understood, although it is clear that oxygen status, phosphorus speciation, temperature, and pH are important variables. Phosphorus release from sediments is usually considered to be constant (usually less than 1 $mg/m^2/day$ under aerobic conditions).

In addition to direct regeneration from sediments, *macrophytes* (large aquatic plants) often play a significant role in phosphorus recycling. Macrophytes with highly developed root systems derive most of their phosphorus from the sediments. Regeneration to the water column can occur by excretion or through decay, effectively "pumping" phosphorus from the sediments. The internal loading generated by recycling is particularly

important in shallow, eutrophic lakes. In several cases where phosphorus inputs have been reduced to control algal blooms, regeneration of phosphorus from phosphorous-rich sediments has slowed the rate of recovery.

13. NITROGEN

Compounds containing nitrogen are not abundant in virgin surface waters. However, nitrogen can reach large concentrations in ground waters that have been contaminated with barnyard runoff or that have percolated through heavily fertilized fields. Sources of surface water contamination include agricultural runoff and discharge from sewage treatment facilities.

Of greatest interest, in order of decreasing oxidation state, are nitrates (NO_3^-), nitrites (NO_2^-), ammonia (NH_3), and organic nitrogen. These three compounds are reported as *total nitrogen*, with units of "mg/L of N" or "mg/L of total N." The concentration of a particular compound is found by multiplying the concentration as N by the molecular weight of the compound and dividing by the atomic weight of nitrogen (14.01).

Excessive amounts of nitrate in water can contribute to the illness in infants known as *methemoglobinemia* ("blue baby" syndrome). As with phosphorous, nitrogen stimulates aquatic plant growth.

Un-ionized ammonia is a colorless gas at standard temperature and pressure. A pungent odor is detectable at levels above 50 mg/L. Ammonia is very soluble in water at low pH.

Ammonia levels in zero-salinity surface water increase with increasing pH and temperature (see Table 25.8). At low pH and temperature, ammonia combines with water to produce ammonium ion (NH_4^+) and hydroxide (OH^-) ions. The ammonium ion is nontoxic to aquatic life and not of great concern. The un-ionized ammonia (NH_3), however, can easily cross cell membranes and have a toxic effect on a wide variety of fish. The EPA has established the following criteria for fresh- and saltwater fish.

freshwater	0.002 mg/L un-ionized ammonia
saltwater	
acute (1 hr average)	0.233 mg/L un-ionized ammonia
chronic (4 hr average)	0.035 mg/L un-ionized ammonia

Table 25.8 *Percent of Total Ammonia Present in Toxic, Un-Ionized Form*

temp	pH								
(°C)	6.0	6.5	7.0	7.5	8.0	8.5	9.0	9.5	10.0
5	0.013	0.040	0.12	0.39	1.2	3.8	11	28	56
10	0.019	0.059	0.19	0.59	1.8	5.6	16	37	65
15	0.027	0.087	0.27	0.86	2.7	8.0	21	46	73
20	0.040	0.13	0.40	1.2	3.8	11	28	56	80
25	0.057	0.18	0.57	1.8	5.4	15	36	64	85
30	0.080	0.25	0.80	2.5	7.5	20	45	72	89

Ammonia is usually measured by a distillation and titration technique or with an ammonia-selective electrode. The results are reported as ammonia nitrogen. Nitrites are measured by a colorimetric method. The results are reported as nitrite nitrogen. Nitrates are measured by ultraviolet spectrophotometry, selective electrode, or reduction methods. The results are reported as nitrate nitrogen. Organic nitrogen is determined by a digestion process that identifies organic and ammonia nitrogen combined. Organic nitrogen is found by subtracting the ammonia nitrogen value from the digestion results.

14. COLOR

Color in water is caused by substances in solution, known as *true color*, and by substances in suspension, mostly organics, known as *apparent* or *organic color*. Iron, copper, manganese, and industrial wastes all can cause color. Color is aesthetically undesirable, and it stains fabrics and porcelain bathroom fixtures.

Water color is determined by comparison with standard platinum/cobalt solutions or by spectrophotometric methods. The standard color scales range from 0 (clear) to 70. Water samples with more intense color can be evaluated using a dilution technique.

15. TURBIDITY

Turbidity is a measure of the light-transmitting properties of water and is comprised of suspended and colloidal material. Turbidity is expressed in *nephelometric turbidity units* (NTU). Viruses and bacteria become attached to these particles, where they can be protected from the bactericidal and viricidal effects of chlorine, ozone, and other disinfecting agents. The organic material included in turbidity has also been identified as a potential precursor to carcinogenic disinfection by-products.

Turbidity in excess of 5 NTU is noticeable by visual observation. Turbidity in a typical clear lake is approximately 25 NTU, and muddy water exceeds 100 NTU. Turbidity is measured using an electronic instrument called a nephelometer, which detects light scattered by the particles when a focused light beam is shown through the sample.

16. SOLIDS

Solids present in a sample of water can be classified in several ways.

- *total solids* (TS): Total solids are the material residue left in the vessel after the evaporation of the sample at 103 to 105°C. Total solids include total suspended solids and total dissolved solids.
- *total suspended solids* (TSS): The material retained on a standard glass-fiber filter disk is defined as the suspended solids in a sample. The

filter is weighed before filtration, dried at 103 to 105°C, and weighed again. The gain in weight is the amount of suspended solids. Suspended solids can also be categorized into *volatile suspended solids* (VSS) and *fixed suspended solids* (FSS).

- *total dissolved solids* (TDS): These solids are in solution and pass through the pores of the standard glass-fiber filter. Dissolved solids are determined by passing the sample through a filter, collecting the filtrate in a weighed drying dish, and evaporating the liquid at 180°C. The gain in weight represents the dissolved solids. Dissolved solids can be categorized into *volatile dissolved solids* (VDS) and *fixed dissolved solids* (FDS).
- *total volatile solids* (TVS): The residue from one of the three previous determinations is ignited to constant weight in an electric muffle furnace at 550°C. The loss in weight during the ignition process represents the volatile solids.
- *total fixed solids* (TFS): The weight of solids that remain after the ignition used to determine volatile solids represents the fixed solids.
- *settleable solids*: The volume (mL/L) of settleable solids is measured by allowing a sample to settle for one hour in a graduated conical container (*Imhoff cone*).

The following relationships exist:

$$TS = TSS + TDS = TVS + TFS \quad 25.9$$

$$TSS = VSS + FSS \quad 25.10$$

$$TDS = VDS + FDS \quad 25.11$$

$$TVS = VSS + VDS \quad 25.12$$

$$TFS = FSS + FDS \quad 25.13$$

Waters with high concentrations of suspended solids are classified as *turbid waters*. Waters with high concentrations of dissolved solids often can be tasted. Therefore, a limit of 500 mg/L has been established as the suggested level for dissolved solids.

17. CHLORINE AND CHLORAMINES

Chlorine is the most common disinfectant used in water treatment. It is a strong oxidizer that deactivates microorganisms. Its oxidizing capability also makes it useful in removing soluble iron and manganese ions.

Chlorine gas in water forms *hydrochloric* and *hypochlorous acids*. At a pH greater than 9, hypochlorous acid dissociates to hydrogen and hypochlorite ions, as shown in Eq. 25.14.

$$Cl_2 + H_2O \underset{pH<4}{\overset{pH>4}{\longleftrightarrow}} HCl + HOCl \underset{pH<9}{\overset{pH>9}{\longleftrightarrow}} H^+ + OCL^- \quad 25.14$$

Free chlorine, hypochlorous acid, and hypochlorite ions left in water after treatment are known as *free chlorine residuals*. Hypochlorous acid reacts with ammonia (if it is present) to form *chloramines*. Chloramines are known as *combined residuals*. Chloramines are more stable than free residuals, but their disinfecting ability is less.

$$HOCl + NH_3 \rightarrow H_2O + NH_2Cl \quad \text{(monochloramine)} \quad 25.15$$

$$HOCl + NH_2Cl \rightarrow H_2O + NHCl_2 \quad \text{(dichloramine)} \quad 25.16$$

$$HOCl + NHCl_2 \rightarrow H_2O + NCl_3 \quad \text{(trichloramine)} \quad 25.17$$

Free and combined residual chlorine can be determined by color comparison, by titration, and with chlorine-sensitive electrodes. Color comparison is the most common field method.

18. HALOGENATED COMPOUNDS

Halogenated compounds have become a subject of concern in the treatment of water due to their potential as carcinogens. The use of chlorine as a disinfectant in water treatment generates these compounds by reacting with organic substances in the water. (For this reason there are circumstances under which chlorine may not be the most appropriate disinfectant.)

The organic substances, called *precursors*, are not in themselves harmful, but the chlorinated end products, known by the term *disinfection by-products* (DBPs) raise serious health concerns. Typical precursors are decay by-products such as humic and fulvic acids. Several of the DBPs contain bromine, which is found in low concentrations in most surface waters and can also occur as an impurity in commercial chlorine gas.

The DBPs can take a variety of forms depending on the precursors present, the concentration of free chlorine, the contact time, the pH, and the temperature. The most common ones are the trihalomethanes (THMs), haloacetic acids (HAAs), dihaloacetonitriles (DHANs), and various trichlorophenol isomers.

19. TRIHALOMETHANES

Only four trihalomethane (THM) compounds are normally found in chlorinated waters.

$CHCl_3$	trichloromethane (chloroform)
$CHBrCl_2$	bromodichloromethane
$CHBr_2Cl$	dibromochloromethane
$CHBr_3$	tribromomethane (bromoform)

The trihalomethanes are the only DBPs currently regulated by the EPA under the National Primary Drinking Water Standards. Because of this, there is a trend toward using treatment and disinfection processes that are designed to minimize the formation of THMs.

20. HALOACETIC ACIDS

The haloacetic acids (HAAs) exist in tri-, di-, and monoforms, abbreviated as THAAs, DHAAs, and MHAAs. All of the haloacetic acids are toxic and are suspected or proven carcinogens. Maximum concentration limits have not been established by the EPA for HAAs.

$C_2HCl_3O_2$	trichloroacetic acid	(TCAA)
$C_2HBrCl_2O_2$	bromodichloroacetic acid	(BDCAA)
$C_2HBr_2ClO_2$	dibromochloroacetic acid	(DBCAA)
$C_2HBr_3O_2$	tribromoacetic acid	(TBAA)
$C_2H_2Cl_2O_2$	dichloroacetic acid	(DCAA)
$C_2H_2BrClO_2$	bromochloroacetic acid	(BCAA)
$C_2H_2Br_2O_2$	dibromoacetic acid	(DBAA)
$C_2H_3ClO_2$	monochloroacetic acid	(MCAA)
$C_2H_3BrO_2$	monobromoacetic acid	(MBAA)

21. DIHALOACETONITRILES

The dihaloacetonitriles (DHANs) are formed when acetonitrile (methyl cyanide: C_2H_3N (structurally H_3CCN)) is exposed to chlorine. All are toxic and suspected carcinogens. Maximum concentration limits have not been established by the EPA for DHANs.

C_2HCl_2N	dichloroacetonitrile	(DCAN)
$C_2HBrClN$	bromochloroacetonitrile	(BCAN)
C_2HBr_2N	dibromoacetonitrile	(DBAN)

22. TRICHLOROPHENOL

Trichlorophenol can exist in six isomeric forms, with varying potential toxicities. As with all halogenated organics, they are potential carcinogens.

2,3,4-trichlorophenol	
2,3,5-trichlorophenol	
2,3,6-trichlorophenol	
2,4,5-trichlorophenol	irritant
2,4,6-trichlorophenol	fungicide, bactericide
3,4,5-trichlorophenol	

23. AVOIDANCE OF DISINFECTION BY-PRODUCTS

Reduction of DBPs can best be achieved by avoiding their production in the first place. The best strategy dictates using source water with few or no precursors.

Often source water choices are limited, necessitating tailoring treatment processes to produce the desired result. This entails removing the precursors prior to the application of chlorine, applying chlorine at certain points in the treatment process that minimize production of DBPs, using disinfectants that do not produce significant DBPs, or a combination of these techniques.

Removal of precursors is achieved by preventing growth of vegetative material (algae, plankton, etc.) in the source water and by collecting source water at various depths to avoid concentrations of precursors. Oxidizers such as potassium permanganate and chlorine dioxide can often reduce the concentration of the precursors without forming the DBPs. Under some instances, application of powdered activated carbon or a pH-adjustment process can reduce the impact of chlorination.

Chlorine application should be delayed if possible until after the flocculation, coagulation, settling, and filtration processes have been completed. In this manner, turbidity and common precursors will be reduced. If it is necessary to chlorinate early to facilitate treatment processes, chlorination can be followed by dechlorination to reduce contact time. Granular activated carbon has been used to some extent to remove DBPs after they form, but the carbon needs frequent regeneration.

Alternative disinfectants include ozone, chloramines, chlorine dioxide, potassium permanganate, and ultraviolet radiation. A combination of ozone and chloramines seems to be the most practical for control of THMs. However, ozone creates other DBPs, including aldehydes, hydrogen peroxide, carboxylic acids, ketones, and phenols. When ozone is used as the primary disinfectant, a secondary disinfectant such as chlorine or chloramine must be used to provide an active residual that can be measured within the distribution system.

PRACTICE PROBLEMS

Phosphorous

1. (*Time limit: one hour*) In a study of a small pond to determine phosphorous impact, the following information was collected.

pond size: 12 ac-ft (14.8×10^6 L)
watershed area: 4 ac (grassland)
average annual rainfall: 5 in
bioavailable P in runoff: 0.01 mg/L
runoff coefficient: 0.1

Biological processes in the pond biota convert phosphorous to a nonbioavailable form at the rate of 22% per year. Recycling of sediment phosphorous by rooted plants and by anaerobic conditions in the hypolimnion converts 12% per year of the nonbioavailable phosphorous back to bioavailable forms.

Runoff into the pond evaporates during the year, so no change in pond volume occurs.

(a) Starting from an initial condition of 0.1 mg/L bioavailable P, what is the P concentration after five annual cycles?

(A) 0.06 mg/L
(B) 0.11 mg/L
(C) 0.13 mg/L
(D) 0.18 mg/L

The answer is (A).

(b) What can be done to reduce the P accumulation?

(A) Add chemicals to precipitate phosphorous in the pond.

(B) Add chemicals to combine with phosphorous in the pond.

(C) Reduce use of phosphorous-based fertilizers in the surrounding fields.

(D) Use natural-based soaps and detergents in the home.

The answer is (C).

Alkalinity

2. (*Time limit: one hour*) Groundwater is used for a water supply. It is taken from the ground at 25°C. The initial properties of the water are as follows.

CO_2	60 mg/L (as $CaCO_3$)
alkalinity	200 mg/L (as $CaCO_3$)
pH	7.1

The water is treated for CO_2 removal by spraying into the atmosphere through a nozzle. The final CO_2 concentration is 5.6 mg/L (as $CaCO_3$) at 25°C. The first ionization constant of carbonic acid is 4.45×10^{-7}. What is the final pH of the water after spraying and recovery, assuming the alkalinity is unchanged in the process?

(A) 7.3

(B) 7.9

(C) 8.4

(D) 8.8

The answer is (B).

Solids

3. (*Time limit: one hour*) The solids content of a stream water sample is to be determined. The total solids content is determined by placing a portion of the sample into a porcelain evaporating dish, drying the sample at 105°C, and igniting the residue by placing the dried sample in a muffle furnace at 550°C. The following masses are recorded.

mass of empty dish: 50.326 g
mass of dish and sample: 118.400 g
mass of dish and dry solids: 50.437 g
mass of dish and ignited solids: 50.383 g

(a) The total solids content is

(A) 900 mg/L

(B) 1000 mg/L

(C) 1100 mg/L

(D) 1600 mg/L

The answer is (D).

(b) The total volatile solids content is

(A) 630 mg/L

(B) 710 mg/L

(C) 790 mg/L

(D) 830 mg/L

The answer is (C).

(c) The total fixed solids content is

(A) 270 mg/L

(B) 300 mg/L

(C) 420 mg/L

(D) 840 mg/L

The answer is (D).

The suspended solids content is determined by filtering a portion of the sample through a glass-fiber filter disk, drying the disk at 105°C, and igniting the residue by placing the dried sample in a muffle furnace at 550°C. The follow masses are recorded.

volume of sample: 30 mL
mass of filter disk: 0.1170 g
mass of disk and dry solids: 0.1278 g
mass of disk and ignited solids: 0.1248 g

(d) The total suspended solids content is

(A) 240 mg/L

(B) 360 mg/L

(C) 370 mg/L

(D) 820 mg/L

The answer is (B).

(e) The volatile suspended solids content is

(A) 100 mg/L

(B) 120 mg/L

(C) 230 mg/L

(D) 640 mg/L

The answer is (A).

(f) The fixed suspended solids content is

(A) 120 mg/L

(B) 180 mg/L

(C) 240 mg/L

(D) 260 mg/L

The answer is (D).

The dissolved solids content is determined by filtering a portion of the sample through a glass-fiber filter disk into a porcelain evaporating dish, drying the sample at 105°C, and igniting the residue by placing the dried sample in a muffle furnace at 550°C. The following masses are recorded.

volume of sample: 25 mL
mass of empty dish: 51.494 g
mass of dish and dry solids: 51.524 g
mass of dish and ignited solids: 51.506 g

(g) The total dissolved solids content is

(A) 1000 mg/L

(B) 1100 mg/L

(C) 1200 mg/L

(D) 1400 mg/L

The answer is (C).

(h) The volatile dissolved solids content is
(A) 680 mg/L
(B) 720 mg/L
(C) 810 mg/L
(D) 900 mg/L

The answer is (B).

(i) The fixed dissolved solids content is
(A) 230 mg/L
(B) 300 mg/L
(C) 410 mg/L
(D) 480 mg/L

The answer is (D).

(j) We would expect the total solids determined in part (a) to be equal to the sum of the total suspended solids determined in (d) plus the total dissolved solids determined in (g). Does the total solids content equal the sum of the suspended and dissolved solids?
(A) yes
(B) no, probably due to poor laboratory technique
(C) no, probably due to rounding of measured values
(D) no, probably because the samples were representative but not identical

The answer is (D).

Hardness

4. (*Time limit: one hour*) The laboratory analysis of a water sample is as follows. All concentrations are "as substance."

Ca^{++}	74.0 mg/L
Mg^{++}	18.3 mg/L
Na^{+}	27.6 mg/L
K^{+}	39.1 mg/L
pH	7.8
HCO_3^{-}	274.5 mg/L
SO_4^{--}	72.0 mg/L
Cl^{-}	49.7 mg/L

(a) The hardness of the water in terms of mg/L of calcium carbonate equivalent is
(A) 1.3 mg/L as $CaCO_3$
(B) 4.7 mg/L as $CaCO_3$
(C) 66 mg/L as $CaCO_3$
(D) 260 mg/L as $CaCO_3$

The answer is (D).

(b) Based on the laboratory analysis, which of the following can be said?
(A) It is surprising that no carbonates were found in the sample.
(B) The cations in solution, when converted to milliequivalents, will equal the anions, when converted to milliequivalents.
(C) The large amount of bicarbonate in the solution tends to make the water acidic.
(D) None of the above can be said.

The answer is (B).

(c) Assuming that hypothetical compounds are formed proportionally to the relative concentrations of ions, the hypothetical concentration of calcium bicarbonate in the sample is
(A) 3.7 meq/L
(B) 4.5 meq/L
(C) 4.7 meq/L
(D) 74 meq/L

The answer is (A).

(d) The hypothetical concentration of magnesium bicarbonate is
(A) 0.8 meq/L
(B) 1.5 meq/L
(C) 1.6 meq/L
(D) 5.2 meq/L

The answer is (A).

(e) The hypothetical concentration of magnesium sulfate is
(A) 0.7 meq/L
(B) 1.5 meq/L
(C) 4.5 meq/L
(D) 5.2 meq/L

The answer is (A).

(f) The hypothetical concentration of sodium sulfate is
(A) 0.8 meq/L
(B) 1.2 meq/L
(C) 1.5 meq/L
(D) 6.4 meq/L

The answer is (A).

(g) The hypothetical concentration of sodium chloride is
(A) 0.2 meq/L
(B) 0.4 meq/L
(C) 1.2 meq/L
(D) 1.4 meq/L

The answer is (B).

(h) The amount of lime (CaO) necessary in a lime softening process to remove the hardness caused by calcium bicarbonate is
(A) 17 mg/L
(B) 28 mg/L
(C) 95 mg/L
(D) 100 mg/L

The answer is (D).

(i) To remove hardness caused by magnesium bicarbonate, it is necessary to raise the pH by adding 35 mg/L of CaO in excess of the stoichiometric requirements. The amount of lime (CaO) necessary to remove the carbonate hardness caused by magnesium bicarbonate is

(A) 12 mg/L
(B) 45 mg/L
(C) 56 mg/L
(D) 80 mg/L

The answer is (D).

(j) The water is subsequently recarbonated to reduce the pH. Assume that by this softening process calcium hardness can be reduced to 30 mg/L and magnesium hardness can be reduced to 10 mg/L, both measured in terms of equivalent calcium carbonate. The amount of hardness that remains in the water is

(A) 10 mg/L as $CaCO_3$
(B) 30 mg/L as $CaCO_3$
(C) 45 mg/L as $CaCO_3$
(D) 75 mg/L as $CaCO_3$

The answer is (D).

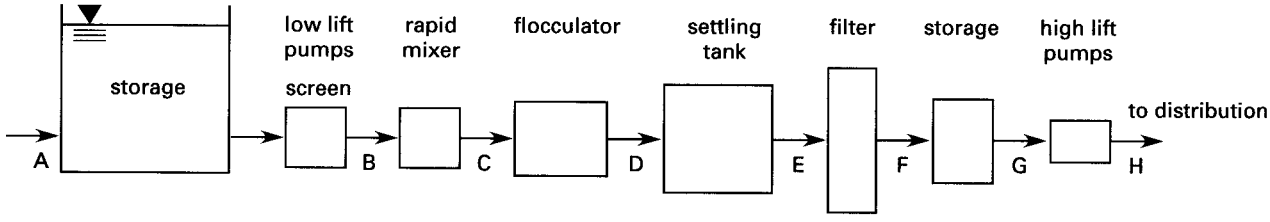
1. WATER TREATMENT PLANT LOCATION

The location chosen for a water treatment plant is influenced by many factors. The most common factors include availability of resources such as (a) local water, (b) power, and (c) sewerage services; economic factors such as (d) land cost and (e) annual taxes; and environmental factors such as (f) traffic and (g) other concerns that would be identified on an environmental impact report.

It is imperative to locate water treatment plants (a) above the flood plain and (b) where a 15 to 20 ft (4.5 to 6 m) elevation difference exists. This latter requirement will eliminate the need to pump the water between processes. Traditional treatment requires a total head of approximately 15 ft (4.5 m), whereas advanced processes such as granular activated charcoal and ozonation increase the total head required to approximately 20 ft (6 m).

The average operational life of equipment and facilities is determined by economics. However, it is unlikely that a lifetime of less than 50 yr would be economically viable. Equipment lifetimes of 25 to 30 yr are typical.



2. PROCESS INTEGRATION

The processes and sequences used in a water treatment plant depend on the characteristics of the incoming water. However, some sequences are more appropriate than others due to economic and hydraulic considerations. *Conventional filtration*, also referred to as *complete filtration*, is a term used to describe the traditional sequence of adding coagulation chemicals, flash mixing, coagulation-flocculation, sedimentation, and subsequent filtration. Coagulants, chlorine (or an alternative disinfectant), fluoride, and other chemicals are added at various points along the path, as indicated by Fig. 26.1. Conventional filtration is still the best choice when incoming water has high color, turbidity, or other impurities.

Direct filtration refers to a modern sequence of adding coagulation chemicals, flash mixing, minimal flocculation, and subsequent filtration. In direct filtration, the physical chemical reactions of flocculation occur to some extent, but special flocculation and sedimentation facilities are eliminated. This reduces the amount of sludge that has to be treated and disposed of. Direct filtration is applicable when the incoming water is of high initial quality.

In-line filtration refers to another modern sequence that starts with adding coagulation chemicals at the filter inlet pipe. Mixing occurs during the turbulent flow toward a filter, which is commonly of the pressure-filter variety. As with direct filtration, flocculation and sedimentation facilities are not used.

Table 26.1 provides guidelines based on incoming water characteristics for choosing processes required to achieve satisfactory quality.

typical flow diagram of water treatment plant

category of chemicals	possible points of application

Note: E = essential, O = optional

[a]Superchlorination shall be followed by dechlorination.

[b]As an alternative, dilute with low chloride water.

[c]Double settling shall be provided for coliform exceeding 20,000 most probably number/100 mL[5].

[d]For extremely muddy water, presedimentation by plain settling may be provided.

[e]mpn = most probable number

3. PRETREATMENT

Preliminary treatment is a general term that usually includes all processes prior to the first flocculation operation (i.e, pretreatment, screening, presedimentation, microstraining, aeration, and chlorination). Flow measurement is usually considered to be part of the pretreatment sequence.

4. SCREENING

Screens are used to protect pumps and mixing equipment from large objects. The degree of screening required will depend on the nature of solids expected. Screens can be either manually or automatically cleaned.

5. MICROSTRAINING

Microstrainers are effective at removing 50 to 95% of the algae in incoming water. Microstrainers are constructed from woven stainless steel fabric mounted on a hollow drum that rotates at 4 to 7 rpm. Flow is usually radially outward through the drum. The accumulated filter cake is removed by backwashing.

6. ALGAE PRETREATMENT

Biological growth in water from impounding reservoirs, lakes, storage reservoirs, and settling basins can be prevented or eliminated with an *algicide* such as copper sulfate. Such growth can produce unwanted taste and odors, clog fine-mesh filters, and contribute to the build-up of slime.

Typical dosages vary from 1.4 to 5.4 lbm/ac-ft (0.5 to 2.0 mg/L), with the lower dose usually being adequate for waters that are soft or have alkalinities less than 50 mg/L as $CaCO_3$. Since it is toxic, copper sulfate should not be used without considering and monitoring the effects on aquatic life (e.g., fish).

7. PRECHLORINATION

A prechlorination process was traditionally employed in most water treatment plants. Many plants have now eliminated all or part of the prechlorination due to the formation of THMs. In so doing, benefits such as algae control have been eliminated. Alternative disinfection chemicals (e.g., ozone and potassium permanganate) can be used. Otherwise, coagulant doses must be increased.

8. PRESEDIMENTATION

The purpose of presedimentation is to remove easily settled sand and grit. This can be accomplished by using pure sedimentation basins, sand and grit chambers, and various passive cyclone degritters. *Trash racks* may be integrated into sedimentation basins to remove leaves and other floating debris.

9. FLOW MEASUREMENT

Flow measurement is incorporated into the treatment process whenever the water is conditioned enough to be compatible with the measurement equipment. Flow measurement devices should not be exposed to scour from grit or highly corrosive chemicals (e.g., chlorine).

Flow measurement often takes place in a Parshall flume. Chemicals may be added in the flume to take advantage of the turbulent mixing that occurs at that point. All of the traditional fluid measurement devices are also applicable, including venturi meters, orifice plates, propeller and turbine meters, and modern passive devices such as magnetic and ultrasonic flowmeters.

10. AERATION

Aeration is used to reduce taste- and odor-causing compounds, to reduce dissolved gases (e.g., hydrogen sulfide), to increase dissolved CO_2 (i.e., recarbonation) or decrease CO_2, to reduce iron and manganese, and to increase dissolved oxygen.

Various types of aerators are used. The best transfer efficiencies are achieved when the air-water contact area is large, the air is changed rapidly, and the aeration period is long. *Force draft air injection* is common. The release depth varies from 10 to 25 ft (3 to 7.5 m). The ideal compression power required to aerate water with a simple air injector depends on the air flow rate, Q, and head (i.e., which must be greater than the release depth), h, at the point where the air is injected. Motor-compression-distribution efficiencies are typically around 75%.

$$P_{\text{kW}} = \frac{Q_{\text{L/s}} h_{\text{m}}}{100} \quad \text{[SI]} \qquad 26.1(a)$$

$$P_{\text{hp}} = \frac{Q_{\text{cfm}} h_{\text{ft}}}{528} \quad \text{[U.S.]} \qquad 26.1(b)$$

Diffused air systems with compressed air at 5 to 10 psig (35 to 70 kPa) are the most efficient methods of aerating water. The air injection rate is 0.2 to 0.3 ft^3/gal. However, the equipment required to produce and deliver compressed air is more complex than with simple injectors. The *transfer efficiency* of a diffused air system varies with depth and bubble size. If coarse bubbles are produced, only 4 to 8% of the available oxygen will be transferred to the water. With medium-sized bubbles, the efficiency can be 6 to 15%, and it can approach 10 to 30% with fine bubble systems.

11. SEDIMENTATION PHYSICS

Water containing suspended sediment can be held in a *plain sedimentation tank* (basin) that allows the particles to settle out.[1] Settling velocity and settling time for sediment depends on the water temperature (i.e., viscosity), particle size, and particle specific gravity. (The specific gravity of sand is usually taken as 2.65.) Typical settling velocities are: gravel, 1 m/s; coarse sand, 0.1 m/s; fine sand, 0.01 m/s; and silt, 0.0001 m/s. Bacteria and colloidal particles are generally considered to be nonsettleable during the detention periods available in water treatment facilities.

Settlement time can be calculated from the settling velocity and the depth of the tank. If it is necessary to determine the settling velocity of a particle with diameter D, the following procedure can be used.[2]

step 1: Assume a settling velocity, v_s.

step 2: Calculate the settling Reynolds number, Re.

$$\text{Re} = \frac{\text{v}_s D}{\nu} \qquad 26.2$$

step 3(a): If Re < 1, use *Stokes' law.*

$$\text{v}_{s,\text{m/s}} = \frac{(\rho_{\text{particle}} - \rho_{\text{water}}) D_{\text{m}}^2 g}{18\mu} = \frac{(\text{SG}_{\text{particle}} - 1) D_{\text{m}}^2 g}{18\nu} \quad \text{[SI]} \qquad 26.3(a)$$

$$\text{v}_{s,\text{ft/sec}} = \frac{(\rho_{\text{particle}} - \rho_{\text{water}}) D_{\text{ft}}^2 g}{18\mu g_c} = \frac{(\text{SG}_{\text{particle}} - 1) D_{\text{ft}}^2 g}{18\nu} \quad \text{[U.S.]} \qquad 26.3(b)$$

[1]The term "plain" refers to the fact that no chemicals are used as coagulants.

[2]This calculation procedure is appropriate for the *Type I settling* that describes sand, sediment, and grit particle performance. It is not appropriate for *Type II settling*, which describes floc and other particles that grow as they settle.

step 3(b): If $1 < \text{Re} < 2000$, use Fig. 26.2, which gives theoretical settling velocities in 68°F (20°C) water for spherical particles with specific gravities of 1.05, 1.2, and 2.65. Actual settling velocities will be much less than shown because particles are not actually spherical.

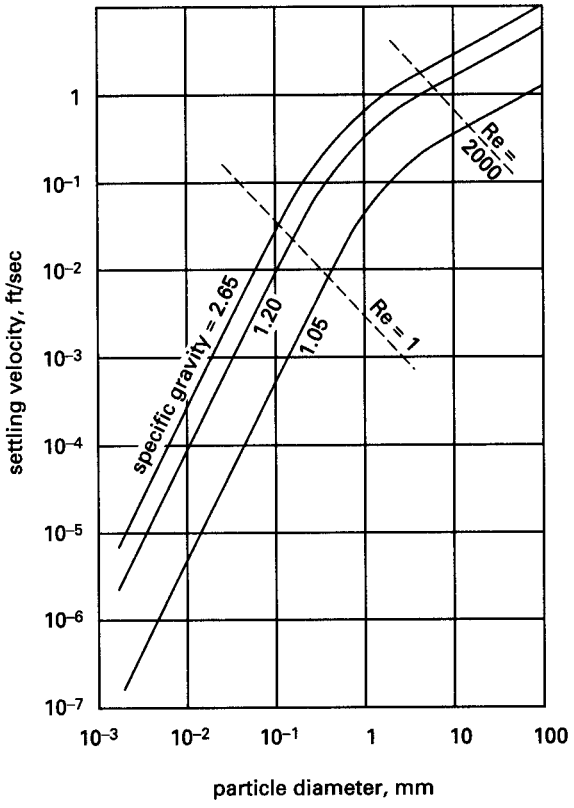

Figure 26.2 *Settling Velocities, 68°F (20°C)*

step 3(c): If $\text{Re} > 2000$, use *Newton's first law of motion* and balance the weight of the particle against the buoyant and drag forces. A spherical shape is often assumed in determining the drag coefficient, C_D.

$$v_s = \sqrt{\frac{4gD(\text{SG}_{\text{particle}} - 1)}{3C_D}} \qquad 26.4$$

12. SEDIMENTATION TANKS

Sedimentation tanks are usually concrete, rectangular, or circular in plan, and are equipped with scrapers or raking arms to periodically remove accumulated sediment. Steel should be used only for small or temporary installations. Where steel parts in unavoidable, as in the case of some rotor parts, adequate corrosion resistance is necessary.

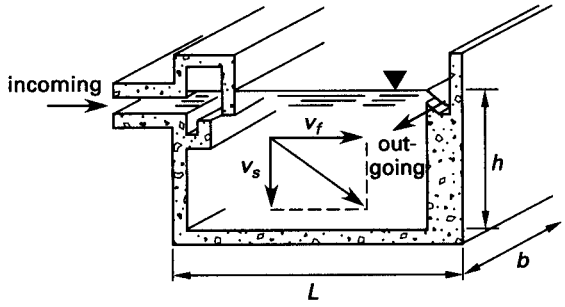

Figure 26.3 *Sedimentation Basin*

Water flows through the tank at the average *flow-through velocity*, v_f. The flow-through velocity can be found by injecting a colored dye into the tank. It should not exceed 1 ft/min (0.5 cm/sec). The time that water spends in the tank depends on the flow-through velocity and the tank length, L, typically 100 to 200 ft (30 to 60 m).

The minimum settling time depends on the tank depth, h, typically 6 to 15 ft (1.8 to 4.5 m).

$$t_{\text{settling}} = \frac{h}{v_s} \qquad 26.5$$

The time that water remains in the basin is known as the *detention time* (*retention time, detention period*, etc.). Typical detention times are 2 to 6 hr, although periods from 1 to 12 hr are used depending on the size of particles. All particles will be removed whose t_{settling} is less than t_d.

$$t_d = \frac{V_{\text{tank}}}{Q} = \frac{Ah}{Q} \qquad 26.6$$

Rectangular basins are preferred. Rectangular basins should be constructed with aspect ratios greater than 3:1, and preferably greater than 4:1. The bottom should be sloped toward the drain at no less than 1%. Multiple inlet ports along the entire inlet wall should be used. If there are fewer than four inlet ports, an inlet baffle should be provided.

Square or circular basins are appropriate only when space is limited. The slope toward the drain should be greater, typically 8%. A baffled center inlet should be provided. For radial-flow basins, the diameter is on the order of 100 ft (30 m).

Basin efficiency can approach 80% for fine sediments. Virtually all of the coarse particles are removed. Theoretically, all particles with settling velocities greater than the *overflow rate*, v^*, also known as the *surface loading* or *critical velocity*, will be removed. In Eq. 26.7, b is the tank width, typically 30 to 40 ft (9 to 12 m). At least two basins should be constructed (both normally operating) so that one can be out of service for cleaning without interrupting plant operation. Therefore, Q_{filter} in Eq. 26.7 should be calculated by dividing the total plant flow by 2 or more. The overflow rate

is typically 600 to 1000 gpd/ft^2 (24 to 40 kL/day·m^2) for rectangular tanks. For square and circular basins, the range is approximately 500 to 750 gpd/ft^2 (20 to 30 kL/day·m^2).

$$v^* = \frac{Q_{\text{filter}}}{A_{\text{surface}}} = \frac{Q_{\text{filter}}}{bL} \qquad 26.7$$

In some modern designs, sedimentation has been enhanced by the installation of vertically inclined *laminar tubes* at the tank bottom. These passive tubes, typically about 2 in (50 mm) in diameter, allow the particles to fall only a short distance in more turbulent water before entering the tube in which the flow is laminar. Incoming solids settle to the lower surface of the tube, slide downward, exit the tube, and settle to the sedimentation basin floor.

The *weir loading* is the daily flow rate divided by the total effluent weir length. Weir loading is commonly specified as 15,000 to 20,000 gal/day-ft (190 to 250 kL/day·m), but certainly less than 50,000 gal/day-ft (630 kL/day·m).

The accumulated sediment is referred to as *sludge*. It is removed either periodically or on a continual basis, when it has reached a concentration of 25 mg/L or is organic. Various methods of removing the sludge are used, including scrapers and pumps. The linear velocity of sludge scrapers should be 15 ft/min (7.5 cm/sec) or higher.

13. COAGULANTS

Various chemicals can be added to remove fine solids. There are two main categories of coagulating chemicals: hydrolyzing metal ions (based on either aluminum or iron) and ionic polymers. Since the chemicals work by agglomerating particles in the water to form floc, they are known as *coagulants*. *Floc* is the precipitate that forms when the coagulant allows the colloidal particles to agglomerate.

Common *hydrolyzing metal ion* coagulants are aluminum sulfate ($Al_2(SO_4)_3 \cdot 14.3H_2O$, commonly referred to as "alum"), ferrous sulfate ($FeSO_4 \cdot 7H_2O$, sometimes referred to as "copperas"), and chlorinated copperas (a mixture of ferrous sulfate and ferric chloride).

Alum is, by far, the most common compound used in water treatment.[3] Alum provides the positive charges needed to attract and neutralize negative colloidal particles. It reacts with alkalinity in the water to form gelatinous aluminum hydroxide ($Al(OH)_3$) in the proportion of 1 mg/L alum:½ mg/L alkalinity. The aluminum hydroxide forms the nucleus for floc agglomeration.

For alum coagulation to be effective, the following requirements must be met: (a) Enough alum must be used to neutralize all of the incoming negative particles. (b) Enough alkalinity must be present to permit as complete as possible a conversion of the aluminum sulfate to aluminum hydroxide. (c) The pH must be maintained between 6 and 7 during flocculation.

Alum reacts with natural alkalinity in the water according to the following reaction. (X is the number of waters of hydration, approximately 14.3.)

$$\begin{aligned} Al_2(SO_4)_3 \cdot XH_2O + 3Ca(HCO_3)_2 \\ \rightarrow 2Al(OH)_3 \downarrow \\ + 3CaSO_4 + 6CO_2 + XH_2O \end{aligned} \qquad 26.8$$

Since alum is naturally acidic, if the water is not sufficiently alkaline, lime (CaO) and soda ash ("caustic soda," Na_2CO_3) can be added for preliminary pH adjustment.[4] If there is inadequate alkalinity and lime is added, the reaction is

$$\begin{aligned} Al_2(SO_4)_3 \cdot XH_2O + 3Ca(OH)_2 \\ \rightarrow 2Al(OH)_3 \downarrow \\ + 3CaSO_4 + XH_2O \end{aligned} \qquad 26.9$$

Alum reacts with soda ash according to

$$\begin{aligned} Al_2(SO_4)_3 \cdot XH_2O + 3Na_2CO_3 + 3H_2O \\ \rightarrow 2Al(OH)_3 \downarrow \\ + 3Na_2SO_4 + 3CO_2 + XH_2O \end{aligned} \qquad 26.10$$

If alkalinity is high, then it may be necessary to use hydrochloric or sulfuric acid for pH control rather than adding lime. The iron salts are effective above a pH of 7, so they may be advantageous in alkaline waters.[5]

Polymers are chains or groups of repeating identical molecules (*mers*) with many available active adsorption sites. Their molecular weights range from several hundred to several million. Polymers can be positively charged (cationic polymers), negatively charged (anionic polymers), or neutral (nonionic polymers). The charge can vary with pH. *Organic polymers* (*polylelectrolytes*) such as starches and polysaccarides and *synthetic polymers* such as polysacylimides are used.

Polymers are useful in specialized situations, such as when particular metallic ions are to be removed. For example, conventional alum will not remove positive iron ions. However, an anionic polymer will combine with the iron. Polymers are effective in narrow ranges of turbidity and alkalinity. In some cases, it may be necessary to artificially seed the water with clay or alum (to produce floc).

14. FLOCCULATION ADDITIVES

Flocculation additives improve the coagulation efficiency by changing the floc size. Additives include *weighting*

[3]Lime is the second most-used compound.

[4]The cost of soda ash used for pH adjustment is about three times that of lime. Also, soda ash leaves sodium ions in solution, an increasingly undesirable contaminant for people with hypertension.

[5]Optimum pH for ferric floc is approximately 7.5. However, iron salts are active over the pH range of 3.8 to 10.

agents (e.g., bentonite clays), *adsorbents* (e.g., powdered activated carbon), and *oxidants* (chlorine). Polymers are also used in conjunction with metallic ion coagulants.

15. COAGULANT DOSES

Feed rate, F, of a compound with purity or fractional availability P can be calculated from the *dose equation*, Eq. 26.11. Doses in mg/L and ppm are the same. Coagulant doses may be given in terms of grains per gallon. There are 7000 grains per pound.

$$F_{\text{kg/day}} = \frac{D_{\text{mg/L}} Q_{\text{ML/day}}}{P} \qquad \text{[SI]} \quad 26.11(a)$$

$$F_{\text{lbm/day}} = \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left(8.345 \frac{\text{lbm-L}}{\text{mg·MG}}\right)}{P} \qquad \text{[U.S.]} \quad 26.11(b)$$

Alum dosage is generally 5 to 50 mg/L, depending on the turbidity. Alum floc is effective within a pH range of 5.5 to 8.0. However, the hydrolysis of the aluminum ion depends on pH and other factors in complex ways, and stoichiometric relationships rarely tell the entire picture.

Ferrous sulfate ($FeSO_4 \cdot 7H_2O$) reacts with slaked lime ($Ca(OH)_2$) to flocculate ferric hydroxide ($Fe(OH)_3$). This is an effective method of clarifying turbid water at higher pH.

Ferric sulfate ($Fe_2(SO_4)_3$) reacts with natural alkalinity and lime. It can also be used for color removal at low pH. At high pH, it is useful for iron and manganese removal, as well as a coagulant with precipitation softening.

Example 26.1

Incoming water contains 2.5 mg/L as a substance of natural alkalinity (HCO_3^-). The flow rate is 2.5 MGD (9.5 ML/day). (a) What feed rate is required if the alum dose is 7 mg/L? (b) How much lime in the form of $Ca(OH)_2$ is required to react completely with the alum?

SI Solution

(a) The dose is specifically in terms of mg/L of alum. Therefore, Eq. 26.11 can be used. Assume $P = 100\%$.

$$F_{\text{kg/day}} = \frac{D_{\text{mg/L}} Q_{\text{ML/day}}}{P} = \frac{\left(7 \frac{\text{mg}}{\text{L}}\right)\left(9.5 \frac{\text{ML}}{\text{day}}\right)}{1.0} = 66.5 \text{ kg/day}$$

The amount calculated should also be adjusted for purity of the alum.

(b) From Eq. 26.8, each alum molecule reacts with six ions of alkalinity.

	$Al_2(SO_4)_3$	+ $6HCO_3^- \rightarrow$
MW:	342	(6)(61)
mg/L:	X	2.5

By simple proportion, the amount of alum used to counteract the natural alkalinity is

$$X = \frac{\left(2.5 \frac{\text{mg}}{\text{L}}\right)(342)}{(6)(61)} = 2.33 \text{ mg/L}$$

The alum remaining is

$$7 \frac{\text{mg}}{\text{L}} - 2.33 \frac{\text{mg}}{\text{L}} = 4.7 \text{ mg/L}$$

From Eq. 26.8, one alum molecule reacts with three slaked lime molecules.

	$Al_2(SO_4)_3$	+ $3Ca(OH)_2 \rightarrow$
MW:	342	(3)(74)
mg/L:	4.7	X

By simple proportion, the amount of lime needed is

$$X = \frac{\left(4.7 \frac{\text{mg}}{\text{L}}\right)(3)(74)}{342} = 3.05 \text{ mg/L}$$

Using Eq. 26.11 and assuming the lime purity is 100%,

$$F_{\text{kg/day}} = \frac{D_{\text{mg/L}} Q_{\text{ML/day}}}{P} = \left(3.05 \frac{\text{mg}}{\text{L}}\right)\left(9.5 \frac{\text{ML}}{\text{day}}\right) = 29.0 \text{ kg/day}$$

Customary U.S. Solution

(a) The dose is specifically in terms of mg/L of alum. Therefore, Eq. 26.11 can be used. Assume $P = 100\%$.

$$F_{\text{lbm/day}} = \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{P} = \frac{\left(7 \frac{\text{mg}}{\text{L}}\right)(2.5 \text{ MGD})\left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{1.0} = 146 \text{ lbm/day}$$

The amount calculated should also be adjusted for purity of the alum.

(b) From Eq. 26.8, each alum molecule reacts with six ions of alkalinity.

	$Al_2(SO_4)_3$	+ $6HCO_3^- \rightarrow$
MW:	342	(6)(61)
mg/L:	X	2.5

By simple proportion, the amount of alum used to counteract the natural alkalinity is

$$X = \frac{\left(2.5\ \frac{\text{mg}}{\text{L}}\right)(342)}{(6)(61)} = 2.33\ \text{mg/L}$$

The alum remaining is

$$7\ \frac{\text{mg}}{\text{L}} - 2.33\ \frac{\text{mg}}{\text{L}} = 4.7\ \text{mg/L}$$

From Eq. 26.8, one alum molecule reacts with three lime molecules.

	$Al_2(SO_4)_3$	+ $3Ca(OH)_2$	→
MW:	342	(3)(74)	
mg/L:	4.7	X	

By simple proportion, the amount of lime needed is

$$X = \frac{\left(4.7\ \frac{\text{mg}}{\text{L}}\right)(3)(74)}{342} = 3.05\ \text{mg/L}$$

Using Eq. 26.11 and assuming the lime purity is 100%,

$$\begin{aligned} F_{\text{lbm/day}} &= \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{P} \\ &= \left(3.05\ \frac{\text{mg}}{\text{L}}\right)(2.5\ \text{MGD})\left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right) \\ &= 63.6\ \text{lbm/day} \end{aligned}$$

16. MIXERS AND MIXING KINETICS

Coagulants and other water treatment chemicals are added in *mixers*. If the mixer adds a coagulant for the removal of colloidal sediment, it may be known as a *flocculator*.

There are two basic models: plug flow mixing and complete mixing. The *complete mixing* model is appropriate when the chemical is distributed throughout by impellers or paddles. If the basin volume is small, so that time for mixing is low, the tank is known as a *flash mixer, rapid mixer*, or *quick mixer*. The volume of flash mixers is seldom greater than 300 ft^3 (8 m^3), and flash mixer detention time is usually 30 to 60 sec. Flash mixing kinetics are described by the complete mixing model.

Flash mixers are usually concrete tanks, square in horizontal cross section, and fitted with vertical shaft impellers. The size of a mixing basin can be determined from various combinations of dimensions that satisfy the volume-flow rate relationship.

$$V = tQ \qquad 26.12$$

The detention time required for complete mixing in a tank of volume V depends on the *mixing rate constant*, K.

$$t_{\text{complete}} = \frac{V}{Q} = \frac{1}{K}\left(\frac{C_i}{C_o} - 1\right) \qquad 26.13$$

The *plug flow mixing* model is appropriate when the water flows through a long narrow chamber, the chemical is added at the entrance, and there is no mechanical agitation. All of the molecules remain in the plug flow mixer for the same amount of time as they flow through. For any mixer, the maximum chemical conversion will occur with plug flow, since all of the molecules have the maximum opportunity to react. The detention time in a plug flow mixer of length L is

$$\begin{aligned} t_{\text{plug flow}} &= \frac{V}{Q} \\ &= \frac{L}{\text{v}_{\text{flow through}}} = \frac{1}{K}\ln\left(\frac{C_i}{C_o}\right) \end{aligned} \qquad 26.14$$

17. MIXING PHYSICS

The drag force on a paddle is given by the standard fluid drag force equation. For flat plates, the coefficient of drag, C_D, is approximately 1.8.

$$F_D = \frac{C_D A \rho g \text{v}^2}{2} \qquad \text{[SI]} \quad 26.15(a)$$

$$F_D = \frac{C_D A \rho g \text{v}^2}{2g_c} = \frac{C_D A \gamma \text{v}^2}{2g} \qquad \text{[U.S.]} \quad 26.15(b)$$

The power required is calculated from the drag force and the mixing velocity. The average *mixing velocity*, v_{mixing}, also known as the *relative paddle velocity*, is the difference in paddle and average water velocities. The mixing velocity is approximately 0.7 to 0.8 times the tip speed.

$$\text{v}_{\text{paddle,ft/sec}} = \frac{2\pi R n_{\text{rpm}}}{60\ \frac{\text{sec}}{\text{min}}} \qquad 26.16$$

$$\text{v}_{\text{mixing}} = \text{v}_{\text{paddle}} - \text{v}_{\text{water}} \qquad 26.17$$

$$P_{\text{kW}} = \frac{F_D \text{v}}{1000\ \frac{\text{W}}{\text{kW}}} \qquad 26.18$$

$$= \frac{C_D A \rho g \text{v}^3}{2\left(1000\ \frac{\text{W}}{\text{kW}}\right)} \qquad \text{[SI]} \quad 26.19(a)$$

$$P_{\text{hp}} = \frac{F_D \text{v}}{550\ \frac{\text{ft-lbf}}{\text{hp-sec}}}$$

$$= \frac{C_D A \gamma \text{v}^3}{2g\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)} \qquad \text{[U.S.]} \quad 26.19(b)$$

For slow-moving paddle mixers, the *velocity gradient*, G, varies from 20 to 75 sec^{-1} for a 15 to 30 minute mixing period. Typical units in Eq. 26.20 are ft-lbf/sec for power (multiply hp by 550 to obtain ft-lbf/sec), lbf-sec/ft^2 for μ, and ft^3 for volume. In the SI system, power in kW is multiplied by 1000 to obtain W, viscosity is in Pa·s, and volume is in m^3. (Multiply viscosity in cP by 0.001 to obtain Pa·s.)

$$G = \sqrt{\frac{P}{\mu V_{\text{tank}}}} \qquad 26.20$$

Equation 26.20 can also be used for rapid mixers, in which case the mean velocity gradient is much higher: approximately 500 to 1000 for 10 to 30 sec mixing period, or 3000 to 5000 for a 0.5 to 1.0 sec mixing period in an in-line blender configuration.

Equation 26.20 can be rearranged to calculate the power requirement. Power is typically 0.5 to 1.5 hp/MGD for rapid mixers.

$$P = \mu G^2 V_{\text{tank}} \qquad 26.21$$

The dimensionless product, Gt_d, of the velocity gradient and detention time is known as the *mixing opportunity parameter*. Typical values range from 10^4 to 10^5.

$$Gt_d = \frac{V_{\text{tank}}}{G}\sqrt{\frac{P}{\mu V_{\text{tank}}}} = \frac{1}{Q}\sqrt{\frac{PV_{\text{tank}}}{\mu}} \qquad 26.22$$

18. IMPELLER CHARACTERISTICS

Mixing equipment uses rotating impellers on rotating shafts. The blades of *radial-flow impellers* (paddle-type impellers, turbine impellers, etc.) are parallel to the drive shaft. *Axial-flow impellers* (propellers, pitched-blade impellers, etc.) have blades inclined with respect to the drive shaft. Axial-flow impellers are better at keeping materials (e.g., water softening chemicals) in suspension.

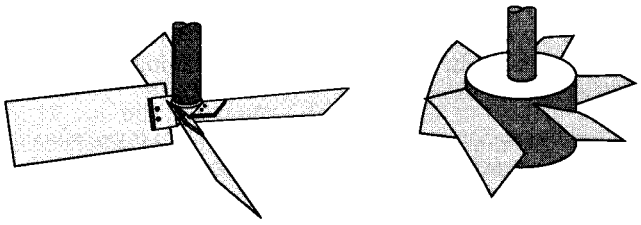

Figure 26.4 *Typical Axial Flow Mixing Impellers*

The *mixing Reynolds number* depends on the impeller diameter, D, suspension specific gravity, SG, liquid viscosity, μ, and rotational speed, n, in rps. Flow is in transition for $10 < \text{Re} < 10{,}000$, is laminar below 10, and is turbulent above 10,000.

$$\text{Re} = \frac{D^2 n \rho}{\mu} \qquad \text{[SI]} \quad 26.23(a)$$

$$\text{Re} = \frac{D^2 n \rho}{g_c \mu} \qquad \text{[U.S.]} \quad 26.23(b)$$

The dimensionless *power number*, N_P, of the impeller is defined implicitly by the power required to drive the impeller. (For any given level of suspension, Eqs. 26.24 through 26.27 apply to geometrically similar impellers and turbulent flow.

$$P = N_P n^3 D^5 \rho \qquad \text{[SI]} \quad 26.24(a)$$

$$P = \frac{N_P n^3 D^5 \rho}{g_c} \qquad \text{[U.S.]} \quad 26.24(b)$$

$$P = \rho g Q h_{\text{v}} \qquad \text{[SI]} \quad 26.25(a)$$

$$P = \frac{\rho g Q h_{\text{v}}}{g_c} \qquad \text{[U.S.]} \quad 26.25(b)$$

The impeller's dimensionless *flow number*, N_Q, is defined implicitly by the *flow rate equation*.

$$Q = N_Q n D^3 \qquad 26.26$$

The velocity head can be calculated from a combination of the power and flow numbers.

$$h_{\text{v}} = \frac{N_P n^2 D^2}{N_Q g} \qquad 26.27$$

Vibration near the critical speed can be a major problem with modern, high-efficiency, high-speed impellers. Mixing speed should be well below the first critical speed of the shaft. Other important design factors include tip speed and shaft bending moment.

19. FLOCCULATION

After flash mixing, the floc is allowed to form during a 20 to 60 min period of gentle mixing. Flocculation is enhanced by the gentle agitation, but the floc disintegrates with violent agitation. During this period, the flow-through velocity should be limited to 0.5 to 1.5 ft/min (0.25 to 0.75 cm/s). The peripheral speed of mixing paddles should vary approximately from 0.5 ft/sec (0.15 m/s) for fragile, cold-water floc to 3.0 ft/sec (0.9 m/s) for warm-water floc.

Many modern designs make use of *tapered flocculation*, also known as *tapered energy*, a process in which the amount (severity) of flocculation gradually decreases as the treated water progresses through the flocculation.

Flocculation is followed by sedimentation for 2 to 8 hr (4 hr typical) in a low-velocity portion of the basin.

(The flocculation time is determined from settling column data.) A good settling process will remove 90% of the settleable solids. Poor design, usually resulting in some form of *short-circuiting* of the flow path, will reduce the effective time in which particles have to settle.

20. FLOCCULATOR-CLARIFIERS

A *flocculator-clarifier* combines mixing, flocculation, and sedimentation into a single tank. Such units are called *solid contact units* and *upflow tanks.* They are generally round in construction, with mixing and flocculation taking place near the central hub and sedimentation occurring at the periphery. Flocculator-clarifiers are most suitable when combined with softening, since the precipitated solids help seed the floc.

Typical operational characteristics of flocculator-clarifiers are as follows.

typical flocculation and mixing time	20 to 60 min
minimum detention time	1.5 to 2.0 hr
maximum weir loading	10 gpm/ft (2 L/s·m)
upflow rate	0.8 to 1.7 gpm/ft^2; 1.0 gpm/ft^2 typical (0.54 to 1.2 L/s·m^2; 0.68 L/s·m^2 typical)
maximum sludge formation rate	5% of water flow

21. SLUDGE QUANTITIES

Sludge is the watery waste that carries off the settled floc and water softening precipitates. The sludge volume produced is given by Eq. 26.28, in which G is the gravimetric fraction of solids. The gravimetric solids fraction for coagulation sludge is generally less than 0.02. For water softening sludge, it is on the order of 0.10. In Eq. 26.28, m_{sludge} can be either a specific quantity or a rate of production per unit time.

$$V_{\text{sludge}} = \frac{m_{\text{sludge}}}{\rho_{\text{water}}(\text{SG})_{\text{sludge}} G} \qquad 26.28$$

The most accurate way to calculate the mass of sludge is to extrapolate from jar or pilot test data. There is no absolute correlation between the mass generated and other water quality measurements. However, a few generalizations are possible. (a) Each unit mass (lbm, mg/L, etc.) of alum produces 0.46 unit mass of floc.[6] (b) 100% of the reduction in suspended solids (expressed as substance) shows up as floc. (c) 100% of any supplemental flocculation aids is recovered in the sludge.

Suspended solids in water may be reported in turbidity units. There is no easy way to calculate total suspended solids (TSS) in mg/L from turbidity in NTU. The ratio of TSS to NTU normally varies from 1.0 to 2.0, and can be as high as 10. A value of 1 or 1.5 is generally appropriate.

The rate of sludge production from coagulation processes can be estimated from Eq. 26.29. M is an extra factor that accounts for the use of any miscellaneous inorganic additives such as clay.

$$m_{\text{sludge,kg/day}} = \frac{\left(86{,}400\ \frac{\text{s}}{\text{day}}\right)(Q_{\text{m}^3/\text{s}})\left(1000\ \frac{\text{L}}{\text{m}^3}\right) \times (0.46 D_{\text{alum,mg/L}} + \Delta\text{TSS}_{\text{mg/L}} + M_{\text{mg/L}})}{1000\ \frac{\text{mg}}{\text{kg}}} \qquad \text{[SI]} \quad 26.29(a)$$

$$m_{\text{sludge,lbm/day}} = \left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right) \times (\text{Q}_{\text{MGD}})(0.46 D_{\text{alum,mg/L}} + \Delta\text{TSS}_{\text{mg/L}} + M_{\text{mg/L}}) \qquad \text{[U.S.]} \quad 26.29(b)$$

After a sludge dewatering process from sludge solids constant G_1 to G_2, the resulting volume will be

$$V_{2,\text{sludge}} \approx V_{1,\text{sludge}}\left(\frac{G_1}{G_2}\right) \qquad 26.30$$

22. FILTRATION

Nonsettling floc, algae, suspended precipitates from softening, and metallic ions (iron and manganese) are removed by filtering. *Sand filters* are commonly used for this purpose. Sand filters are beds of gravel, sand, and other granulated materials.[7]

Although filter box heights are on the order of 10 ft (3 m) to provide for expansion and freeboard during backwashing, the almost-universal specification used before 1960 for a single-media filter was 24 to 30 in (610 to 760 mm) of sand or ground coal. Filters are usually square or nearly square in plan, and they operate with a hydraulic head of 1 to 8 ft (0.3 to 2.4 m).

Although most plants have six or more filters, there should be at least three filters so that two can be operational when one is being cleaned. Cleaning of multiple filters should be staged.

Filter operation is enhanced when the top layer of sand is slightly more coarse than the deeper sand. During backwashing, however, the finest sand rises to the top. Various *dual-layer* and *multi-layer* (also known as *dual-media* and *multi-media*) filter designs using layers of coal

[6] Some researchers report other ratios, including 0.26. However, 0.456 is the stoichiometric ratio, as determined from Eq. 26.8.

[7] Most sand filter beds were designed when a turbidity level of 5 NTU was acceptable. With the U.S. federal MCL at 1 NTU, some states at 0.5 NTU, and planning "on the horizon" for 0.2 NTU, these conventional filters are clearly inadequate.

("anthrafilt") and (more recently) granular activated carbon, alone or in conjunction with sand, overcome this problem. Since coal has a lower specific gravity than sand, media particle size is larger, as is pore space.

Historically, the *loading rate* (*flow rate*) was set at 2 to 3 gpm/ft^2 (1.4 to 2.0 L/s·m^2) for *rapid sand filters.* 4 to 6 gpm/ft^2 (2.7 to 4.1 L/s·m^2) is a reasonable minimum rate for dual-media filters. Multi-media filters operate at 5 to 10 gpm/ft^2 (3.4 to 6.8 L/s·m^2) and above.[8] The filter loading rate is

$$\text{loading rate} = \frac{Q}{A} \qquad 26.31$$

Filters discharge into a storage reservoir known as a *clearwell.* The *hydraulic head* (the distance between the water surfaces in the filter and clearwell) is usually 9 to 12 ft (2.7 to 3.6 m). This allows for a substantial decrease in available head prior to backwashing. Clearwell storage volume is 30 to 60% of the daily filter output, with a minimum capacity of 12 hr of the maximum daily demand so that demand can be satisfied from the clearwell while the filter is being cleaned or serviced.

23. FILTER BACKWASHING

The most common type of service needed by filters is backwashing, which is needed when the pores between the filter particles clog up. Typically, this occurs after 1 to 3 days of operation, when the head loss reaches 6 to 8 ft (1.6 to 2.4 m). There are two parameters that can trigger backwashing: head loss and turbidity. Head loss increases almost linearly with time, while turbidity remains constant for several days before suddenly increasing. The point of sudden increase is known as *breakthrough.*[9] Since head loss is more easily monitored than turbidity, it is desired to have head loss trigger the backwashing cycle.

Backwashing with filtered water pumped back through the filter from the bottom to the top expands the sand layer 30 to 50%, which dislodges trapped material. Backwashing for 3 to 5 min at 8 to 15 gpm/ft^2 (5.4 to 10 L/s·m^2) is a typical specification.[10] The head loss is reduced to approximately 1 ft (0.3 m) after washing.

Experience has shown that supplementary agitation of the filter media is necessary to prevent "caking" and "mudballs" in almost all installations. Prior to backwashing, the filter material may be expanded by an *air prewash* volume of 1 to 8 (2 to 5 typical) times the sand filter volume per minute for 2 to 10 (3 to 5 typical) min. Alternatively, turbulence in the filter material may be encouraged during backwashing with an *air wash* or with rotating hydraulic surface jets.

During backwashing, the rate at which the water rises in the filter housing will be 1 to 3 ft/min (0.5 to 1.5 cm/s). This rise should not exceed the settling velocity of the smallest particle that is to be retained in the filter. The wash water, which is collected in troughs for disposal, constitutes approximately 1 to 5% of the total processed water. The total water used is approximately 75 to 100 gal/ft^2 (3 to 4 kL/m^2). The actual amount of backwash water is

$$Q = t_{\text{backwash}} A_{\text{filter}} (\text{rate of rise}) \qquad 26.32$$

The temperature of the water used in backwashing is important since the density changes. 40°F (4°C) water is significantly more dense than 70°F (21°C) water. Media particles, therefore, may be expanded to the same extent using lower upflow rates at the lower backwash temperature.

24. OTHER FILTRATION METHODS

Pressure filters operate similarly to rapid sand filters except that incoming water is pressurized up to 25 ft (0.75 m) gage. Filter rates are 2 to 4 gpm/ft^2 (1.4 to 2.7 L/s·m^2). Pressure filters are not used in large installations.

Ultrafilters are membranes that act as sieves to retain turbidity, microorganisms, and large organic molecules that are THM precursors, while allowing water, salts, and small molecules to pass through. Ultrafiltration is effective in removing particles ranging in size of 0.001 to 10 μm.[11] A pressure of 15 to 75 psig (100 to 500 kPa) is required to drive the water through the membrane.

Biofilm filtration (*biofilm process*) uses microorganisms to remove selected contaminants (e.g., aromatics and other hydrocarbons). Operation of biofilters is similar to trickling filters used in wastewater processing. Sand filter facilities are relatively easy to modify—sand is replaced with gravel in the 4 to 14 mm size range, application rates are decreased, and exposure to chlorine from incoming and backwash water is eliminated.

Slow sand filters are primarily of historical interest, though there are some similarities with modern biomethods used to remediate toxic spills. Slow sand filters operate similarly to rapid sand filters except that the exposed surface (loading) area is much larger and the flow rate is much lower (0.05 to 0.1 gpm/ft^2; 0.03 to 0.07 L/s·m^2). Slow sand filters are limited to low turbidity applications not requiring chemical treatment and where large rural areas are available to spread out the facilities. Slow sand filters can be operated as biofilm processes if a layer of biological slime is allowed to form on the top of the filter medium.[12] Slow filter cleaning usually involves removing a few inches of sand.

[8] Recent testing has demonstrated that deep-bed, uniformly graded anthracite filters can operate at 10 to 15 gpm/ft^2 (7 to 10 L/s·m^2), although this requires high-efficiency preozonation and microflocculation.

[9] Technically, *breakthrough* is the point at which the turbidity rises above the MCL permitted. With low MCLs, this occurs very soon after the beginning of filter performance degradation.

[10] While the maximum may never be used, a maximum backwash rate of 20 gpm/ft^2 (14 L/s·m^2) should be provided for.

[11] A μm is the same as a micron.

[12] The biological slime is called *schmutzdecke.*

25. ADSORPTION

Many dissolved organic molecules and inorganic ions can be removed by adsorption processes. *Adsorption* is not a filtration process, but occurs when contaminants are trapped on the surface or interior of the adsorption particles.

Granular activated carbon (GAC) is considered to be the best available technology for removal of THMs and synthetic organic chemicals from water. GAC is also useful in removing compounds that contribute to taste, color, and odor. Activated carbon can be used in the form of powder (which must be subsequently removed) or granules. GAC can be integrated into the design of sand filters.[13]

Eventually, the GAC becomes saturated and must be removed and reactivated. In such dual-media filters, the reactivation interval for GAC is approximately 1 to 2 yr.

26. FLUORIDATION

Fluoridation can occur any time after filtering and can involve solid compounds or liquid solutions. Small utilities may manufacturer their own liquid solution on-site from sodium silicofluoride (Na_2SiF_6, typically 22 to 30% purity) or sodium fluoride (NaF, typically 90 to 98% purity) for use with a volumetric metering system. Larger utilities use gravimetric dry feeders with sodium silicofluoride (Na_2SiF_6, typically 98 to 99% purity) or solution feeders with fluorsilic acid (H_2SiF_6).

[13]For example, an 80 inch GAC layer may be placed on top of a 40 inch sand layer.

Assuming 100% ionization, the application rate, F (in pounds per day), of a compound with fluoride gravimetric fraction, G, and a fractional purity, P, needed to obtain a final concentration, C, of fluoride is

$$F_{\text{kg/day}} = \frac{C_{\text{mg/L}} Q_{\text{L/d}}}{PG} \qquad \text{[SI]} \quad 26.33(a)$$

$$F_{\text{lbm/day}} = \frac{C_{\text{mg/L}} Q_{\text{MGD}} \left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{PG} \qquad \text{[U.S.]} \quad 26.33(b)$$

27. IRON AND MANGANESE REMOVAL

Several methods can be used to remove iron and manganese. Most involve aeration with chemical oxidation since manganese is not easily removed by aeration alone. These processes are described in Table 26.2.

28. TASTE AND ODOR CONTROL

A number of different processes affect taste and odor. Some are more effective and appropriate than others. *Microstraining*, using a 35 μm or finer metal cloth, can be used to reduce the number of algae and other organisms in the water, since these are sources of subsequent tastes and odors. Microstraining does not remove dissolved or colloidal organic material, however.

Table 26.2 *Processes for Iron and Manganese Removal*

processes	iron and/or manganese removed	pH required	remarks
aeration, settling, and filtration	ferrous bicarbonate	7.5	provide aeration unless incoming water contains adequate dissolved oxygen
	ferrous sulfate	8.0	
	manganous bicarbonate	10.3	
	manganous sulfate	10.0	
aeration, free residual chlorination, settling, and filtration	ferrous bicarbonate	5.0	provide aeration unless incoming water contains adequate dissolved oxygen
	manganous bicarbonate	9.0	
aeration, lime softening, settling, and filtration	ferrous bicarbonate	8.5–9.6	
	manganous bicarbonate		
aeration, coagulation, lime softening, settling, and filtration	colloidal or organic iron	8.5–9.6	require lime, and alum or iron coagulant
	colloidal or organic manganese	10.0	
ion exchange	ferrous bicarbonate	≈ 6.5	water must be devoid of oxygen
	manganous bicarbonate		iron and managanese in raw water not to exceed 2.0 mg/L
			consult manufacturers for type of ion exchange resin to be used

Aeration can be used when dissolved oxygen is low or when hydrogen sulfide is present. Aeration has little effect on most other tastes and odors.

Chlorination improves taste and reduces odors caused by organic matter and industrial wastes. Normally, the dosage required will be several times greater than those for ordinary disinfection, and the term *superchlorination* is used to describe applying enough chlorine to maintain an excessively large residual. Subsequent dechlorination will be required to remove the excess chlorine. Similar results will be obtained with chlorine dioxide and other disinfection products.

Activated charcoal removes more tastes and odors, as well as a wide variety of chemical contaminants.

29. PRECIPITATION SOFTENING

Precipitation softening using the *lime-soda ash process* adds lime (CaO), also known as *quicklime*, and soda ash (Na_2CO_3) to remove calcium and magnesium from hard water.[14] Granular quicklime is available with a minimum purity of 90%, and soda ash is available with a 98% purity.

Lime forms *slaked lime* (also known as *hydrated lime*), $Ca(OH)_2$, in an exothermic reaction when added to feed water. The slaked lime is delivered to the water supply as a *milk of lime* suspension.

$$CaO + H_2O \rightarrow Ca(OH)_2 + \text{heat} \qquad 26.34$$

Slaked lime reacts first with any carbon dioxide dissolved in the water, as in Eq. 26.35. No softening occurs, but the carbon dioxide demand must be satisfied before any reactions involving calcium or magnesium can occur.

carbon dioxide removal:

$$CO_2 + Ca(OH)_2 \rightarrow CaCO_3\downarrow + H_2O \qquad 26.35$$

Lime next reacts with any carbonate hardness, precipitating calcium carbonate and magnesium hydroxide as shown in Eqs. 26.36 and 26.37. Note that removal of carbonate hardness caused by magnesium (characterized by magnesium bicarbonate in Eq. 26.37) requires two molecules of calcium hydroxide to precipitate calcium carbonate and magnesium hydroxide.

calcium carbonate hardness removal:

$$Ca(HCO_3)_2 + Ca(OH)_2 \rightarrow 2CaCO_3\downarrow + 2H_2O \qquad 26.36$$

magnesium carbonate hardness removal:

$$Mg(HCO_3)_2 + 2Ca(OH)_2 \rightarrow 2CaCO_3\downarrow + Mg(OH)_2\downarrow + 2H_2O \qquad 26.37$$

[14]Soda ash does not always need to be used. When lime alone is used, the process may be referred to as *lime softening*.

To remove noncarbonate hardness (characterized by magnesium sulfate in Eq. 26.39), it is necessary to add soda ash. The sodium sulfate that remains in solution does not contribute to hardness, for sodium is a single-valent ion (i.e., Na^+).

magnesium noncarbonate hardness removal:

$$MgSO_4 + Ca(OH)_2 \rightarrow Mg(OH)_2\downarrow + CaSO_4 \qquad 26.38$$

calcium noncarbonate hardness removal:

$$CaSO_4 + Na_2CO_3 \rightarrow CaCO_3\downarrow + Na_2SO_4 \qquad 26.39$$

The calcium ion can be effectively reduced by the lime addition shown in the previous equations, raising the pH of the water to approximately 10.3. (Thus, the lime added removes itself.) Precipitation of the magnesium ion, however, demands a higher pH and the presence of excess lime in the amount of about 35 mg/L of CaO or 50 mg/L of $Ca(OH)_2$ above the stoichiometric requirements. The practical limits of precipitation softening are 30 to 40 mg/L of $CaCO_3$ and 10 mg/L of $Mg(OH)_2$, both as $CaCO_3$.

After softening, the water must be recarbonated to lower its pH and to reduce its scale-forming potential. This is accomplished by bubbling carbon dioxide gas through the water.

$$Ca(OH)_2 + CO_2 \rightarrow CaCO_3\downarrow + H_2O \qquad 26.40$$

The treatment process could be designed such that all of these reactions take place sequentially. That is, first slaked lime would be added (Eqs. 26.36 and 26.37), then the water would be recarbonated (Eq. 26.40), then excess lime would be added to raise the pH, followed by soda ash treatment and recarbonation. In fact, essentially such a sequence is used in a *double-stage process:* two chemical application points and two recarbonation points.

A *split process* can be used to reduce the amount of lime that is neutralized in recarbonation. The excess lime needed to raise the pH is added prior to the first flocculator/clarifier stage. The soda ash is added to the first stage effluent, prior to the second flocculator/clarifier stage. Recarbonation, if used, is applied to the effluent of the second stage. A portion of the flow is bypassed (i.e., is not softened) and is later recombined with softened water to obtain the desired hardness.

Example 26.2

Water contains 130 mg/L of calcium bicarbonate ($Ca(HCO_3)_2$) as $CaCO_3$. How much slaked lime ($Ca(OH)_2$) is required to remove the hardness?

Solution

The hardness is given as a $CaCO_3$ equivalent. Therefore, the amount of slaked lime is implicitly the same: 130 mg/L as $CaCO_3$. Appendix 22.C can be used to convert the quantity to an "as substance" measurement. From App. 22.C, the conversion factor for $Ca(OH)_2$ is 1.35.

$$\text{Ca(OH)}_2: \quad \frac{130\ \frac{\text{mg}}{\text{L}}}{1.35} = 96.3\ \text{mg/L as substance}$$

Example 26.3

Water is received with the following characteristics.

total hardness	250 mg/L as $CaCO_3$
alkalinity	150 mg/L as $CaCO_3$
carbon dioxide	5 mg/L as substance

The water is to be treated with precipitation hardening and recarbonation. Lime (90% pure) and soda ash (98% pure) are available.

What stoichiometric amounts (as substance) of slaked lime, soda ash, and carbon dioxide are required to reduce the hardness of the water to zero?

Solution

First, convert the carbon dioxide concentration to a $CaCO_3$ equivalent. From App. 22.C, the factor is 2.27.

$$\text{CO}_2: \quad \left(5\ \frac{\text{mg}}{\text{L}}\right)(2.27) = 11.35\ \text{mg/L as CaCO}_3$$

Since the alkalinity is less than the hardness and no hydroxides or calcium are reported, it is concluded that the carbonate hardness is equal to the alkalinity, and the noncarbonate hardness is equal to the difference in total hardness and alkalinity.

Since the alkalinity is reported as a $CaCO_3$ equivalent, the first-state treatment to remove carbon dioxide and carbonate hardness requires lime in the amount of

$$\text{Ca(OH)}_2: \quad 11.35\ \frac{\text{mg}}{\text{L}} + 150\ \frac{\text{mg}}{\text{L}} = 161.35\ \text{mg/L as CaCO}_3$$

Approximately 35 mg/L are added to raise the pH so that the noncarbonate hardness can be removed.

$$\text{Ca(OH)}_2: \quad 161.35\ \frac{\text{mg}}{\text{L}} + 35\ \frac{\text{mg}}{\text{L}} = 196.35\ \text{mg/L as CaCO}_3$$

Use the 90% fractional purity and App. 22.C to convert to quantity as substance.

$$\text{Ca(OH)}_2: \quad \frac{196.35\ \frac{\text{mg}}{\text{L}}}{(1.35)(0.9)} = 161.6\ \text{mg/L as substance}$$

The noncarbonate hardness is

$$250\ \frac{\text{mg}}{\text{L}} - 150\ \frac{\text{mg}}{\text{L}} = 100\ \text{mg/L as CaCO}_3$$

The soda ash requirement is

$$\text{Na}_2\text{CO}_3: \quad \frac{100\ \frac{\text{mg}}{\text{L}}}{(0.94)(0.98)} = 108.6\ \text{mg/L as substance}$$

The recarbonation required to lower the pH depends on the amount of excess lime added.

$$\text{CO}_2: \quad \frac{35\ \frac{\text{mg}}{\text{L}}}{2.27} = 15.42\ \text{mg/L}$$

30. ADVANTAGES AND DISADVANTAGES OF PRECIPITATION SOFTENING

Precipitation softening is relatively inexpensive for large quantities of water. Both alkalinity and total solids are reduced. The high pH and lime help disinfect the water.

However, the process produces large quantities of sludge that constitute a disposal problem. The intrinsic solubility of some of the compounds means that complete softening cannot be achieved. Flow rates and chemical feed rates must be closely monitored.

31. WATER SOFTENING BY ION EXCHANGE

In the *ion exchange process* (also known as the *zeolite process* and the *base exchange method*), water is passed through a filter bed of exchange material. Ions in the insoluble exchange material are displaced by ions in the water. The processed water leaves with zero hardness. However, since there is no need for water with zero hardness, some of the water is typically bypassed around the process.

If dissolved solids or sodium concentration of the water are issues, then ion exchange may not be suitable.

There are several types of ion exchange materials. *Green sand* (*glauconite*) is a natural substance that is mined and treated with manganese dioxide. Green sand is not used commercially.

Synthetic zeolites have historically been the workhorses for water softening and demineralization. Porosity through continuous-phase *gelular resins* is low, and dry contact surface areas of 500 ft^2/lbm (0.1 m^2/g) or less is common. This makes gel-based zeolites suitable only for small volumes.

Synthetic *macroporous resins* (*macroreticular resins*) are suitable for use in large-volume water processing systems, when chemical resistance is required, and when specific ions are to be removed. These are discontinuous, three-dimensional copolymer beads in a rigid-sponge

type formation.[15] Each bead is made up of thousands of microspheres of the resin. Porosity is much higher than with gelular resins, and dry contact surface areas are approximately 270,000 to 320,000 ft^2/lbm (55 to 65 m^2/g).

There are four primary resin families: strong acid, strong base, weak acid, and weak base. Each family has different resistances to fouling by organic and inorganic chemicals, stabilities, and lifetimes. For example, strong acid resins can last for 20 years. Strong base resins, on the other hand, may have lifetimes of only 3 years. Each family can be used in either gelular or macroporous forms.

During operation, calcium and magnesium ions in hard water are removed according to the following reaction in which R is the zeolite anion. The resulting sodium compounds are soluble.

$$\left\{\begin{matrix}\text{Ca}\\\text{Mg}\end{matrix}\right\}\left\{\begin{matrix}(HCO_3)_2\\SO_4\\Cl_2\end{matrix}\right\} + Na_2R \rightarrow Na_2\left\{\begin{matrix}(HCO_3)_2\\SO_4\\Cl_2\end{matrix}\right\} + \left\{\begin{matrix}\text{Ca}\\\text{Mg}\end{matrix}\right\}R \qquad 26.41$$

Typical saturation capacities of synthetic resins are 1.0 to 1.5 meq/mL for anion exchange resins and 1.7 to 1.9 meq/mL for cation exchange resins. However, working capacities are more realistic measures than saturation capacities. The specific working capacity for zeolites is approximately 3 to 11 kilograins/ft^3 (6.9 to 25 kg/m^3) of hardness before regeneration.[16] For synthetic resins, the specific working capacity is approximately 10 to 15 kilograins/ft^3 (23 to 35 kg/m^3) of hardness.

The volume of water that can be softened per cycle (between regenerations) is

$$V_{\text{water}} = \frac{(\text{specific working capacity})(V_{\text{exchange material}})}{\text{hardness}} \qquad 26.42$$

Flow rates are typically 1 to 6 gpm/ft^3 (2 to 13 L/s·m^3) of resin volume. The flow rate across the exposed surface will depend on the geometry of the bed, but values of 3 to 15 gpm/ft^2 (2 to 10 L/s·m^2) are typical.

Example 26.4

A municipal plant processes water with a total initial hardness of 200 mg/L. The desired discharge hardness is 50 mg/L. If an ion exchange process is used, what is the bypass factor?

Solution

The water passing through the ion exchange unit is reduced to zero hardness. If x is the water fraction bypassed around the zeolite bed,

$$(1-x)(0) + x\left(200\ \frac{\text{mg}}{\text{L}}\right) = 50\ \text{mg/L}$$

$$x = 0.25$$

32. REGENERATION OF ION EXCHANGE RESINS

Ion exchange material has a finite capacity for ion removal. When the zeolite approaches saturation, it is regenerated (rejuvenated). Standard ion exchange units are regenerated when the alkalinity of their effluent increases to the *set point.* Most units that collect *crud* are operated to a pressure-drop endpoint.[17] The pressure drop through the ion exchange unit is primarily dependent on the amount of crud collected.

Regeneration of synthetic ion exchange resins is accomplished by passing a *regenerating solution* over/through the resin. Although regeneration can occur in the ion exchange unit itself, external regeneration is becoming common. This involves removing the bed contents hydraulically, backwashing to separate the components (for mixed beds), regenerating the bed components separately, washing, and then recombining and transferring the bed components back into service. For complete regeneration, a contact time of 30 to 45 minutes may be required.

Common regeneration compounds are NaCl (for water hardness removal units), H_2SO_4 (for cation exchange resins), and NaOH (for anion exchange resins). The amount of regeneration solution depends on the resin's degree of saturation. A rule of thumb is to expect to use 5 to 25 pounds of regeneration compound per cubic foot of resin (80 to 400 kilograms per cubic meter). Alternatively, dosage of the regeneration compound may be specified in terms of hardness removed (e.g., 0.4 lbm of salt per 1000 grains of hardness removed.)

The salt requirement per regeneration cycle is

$$m_{\text{salt}} = (\text{specific working capacity})(V_{\text{exchange material}}) \times (\text{salt requirement}) \qquad 26.43$$

33. STABILIZATION

Stabilization treatment is used to eliminate or reduce the potential for scaling and corrosion in pipes after the treated water is distributed. Various factors influence the stability of water, including temperature, dissolved

[15]The differences in structure between gel polymers and macroporous polymers occur during the polymerization step. Either can be obtained from the same zeolite.

[16]There are 7000 grains in a pound. 1000 grains of hardness (i.e., 1/7 of a pound) is known as a *kilograin.* It should not be confused with a kilogram. Other conversions are 1 grain = 64.8 mg and 1 grain/gal = 17.12 mg/L.

[17]Since water has been filtered before reaching the zeolite bed, *crud* consists primarily of iron-corrosion products ranging from dissolved to particulate matter.

oxygen, dissolved solids, pH, and alkalinity. Different pipe materials are more susceptible to corrosion than others, as are combinations of pipe fitting materials.[18]

Stability is a general term used to describe the water's tendency to be corrosive. Three indices are commonly used to quantify water stability: the *Langelier index*, LI (or *Langelier saturation index*, SI), the *Ryznar index*, and the *aggressive index*. Table 26.3 describes water stability in terms of these indices.

Table 26.3 *Stability of Water*

characteristics	Langelier index	aggressive index	Ryznar index
highly aggressive	< -2	< 10	> 10
moderately aggressive	-2 to 0	10 to 12	6 to 10
nonaggressive	> 0	> 12	< 6

In Eq. 26.44, pH_{sat} is the saturation pH (i.e., the pH at $CaCO_3$ saturation), M is the alkalinity in mg/L as $CaCO_3$, and Ca is the calcium ion content in mg/L as $CaCO_3$. If the Langelier stability index is positive, the water will continue to deposit $CaCO_3$ in the water lines downstream. A corrosive water will have a negative stability index.

$$LI = pH - pH_{sat} \qquad 26.44$$

$$pH_{sat} = (pK_2 - pK_1) + pCa + pM$$
$$= -\log\left(\frac{K_2}{K_1}\right)[Ca^{++}][M] \qquad 26.45$$

K_2 is the second ionization constant for H_2CO_3, and K_1 is the solubility product constant for $CaCO_3$. The quantity $(pK_2 - pK_1)$ depends in a complex manner on the total ion strength (or total dissolved solids) and the water temperature.

The Ryznar index, RI, is similar.

$$RI = 2pH_{sat} - pH \qquad 26.46$$

The main stabilization processes are pH and alkalinity adjustment using lime or soda ash (if the pH is too low), and with carbon dioxide, sulfuric acid, or hydrochloric acid if the pH is too high. When lime is used for pH adjustment, care must be exercised that unreacted lime does not form *clinker* particles that can be carried out into the water distribution system.

Corrosion and scaling can also be prevented within the treatment plant by use of protective pipe linings and coatings. Various inhibitors and sequestering agents can be used.[19]

[18]The galvanic series is useful in predicting the likelihood of corrosion between pipe fittings of different materials.

[19]A *sequestering agent* is a compound that is useful in corrosion control. Such agents work by sequestering normally positive ions in a complex negative ion.

34. DISINFECTION

Chlorination is commonly used for disinfection. Chlorine can be added as a gas or as a liquid. (If it is added to the water as a gas, it is stored as a liquid which vaporizes around $-31°F$ ($-35°C$). Liquid chlorine is the primary form used since it is less expensive than calcium hypochlorite solid ($Ca(OCl)_2$) and sodium hypochlorite ($NaOCl$).

Chlorine is corrosive and toxic. Special safety and handling procedures must be followed with its use.

35. CHLORINATION CHEMISTRY

When chlorine gas dissolves in water, it forms hydrochloric acid (HCl) and hypochlorous acid (HOCl).

$$Cl_2 + H_2O \rightarrow HCl + HOCL \qquad 26.47$$

$$HCl \rightarrow H^+ + Cl^- \qquad 26.48$$

$$HOCl \leftrightarrow H^+ + OCl^- \qquad 26.49$$

The fraction of HOCl ionized into H^+ and OCl^- depends on the pH and can be determined from Fig. 26.5.

When calcium hypochlorite solid is added to water, the ionization reaction is

$$Ca(OCl)_2 \rightarrow Ca^{++} + 2OCl^- \qquad 26.50$$

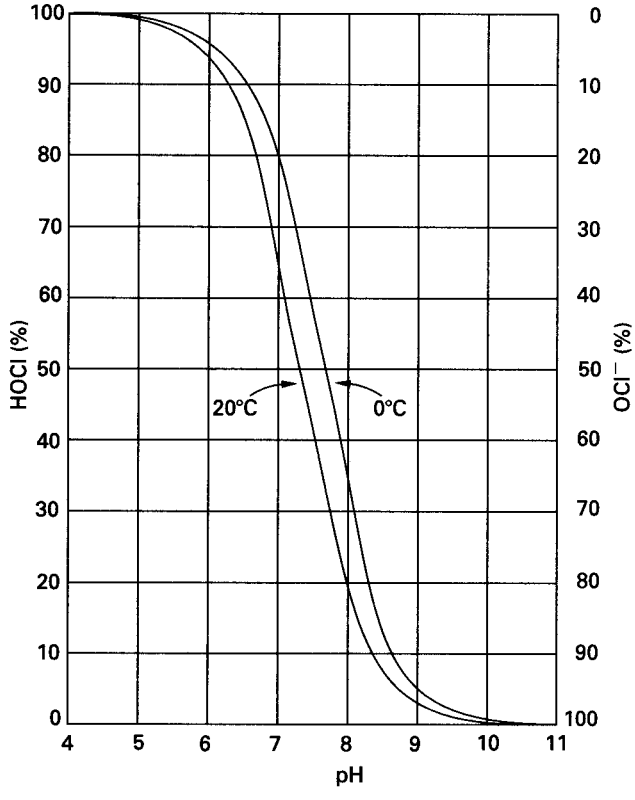

Figure 26.5 *Ionized HOCl Fraction vs. pH*

36. CHLORINE DOSE

Figure 26.6 illustrates a breakpoint chlorination curve. Basically, the concept of *breakpoint chlorination* is to continue adding chlorine until the desired quantity of free residuals appears. This cannot occur until after the demand for combined residuals has been satisfied.

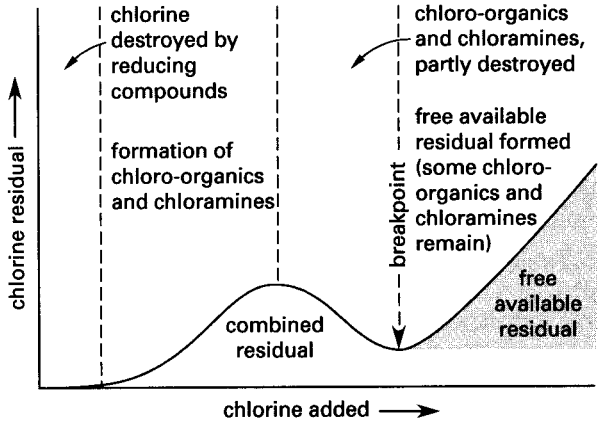

Figure 26.6 *Breakpoint Chlorination Curve*

The amount of chlorine necessary for disinfection varies with the organic and inorganic material present in the water, the pH, the temperature, and the contact time. Thirty minutes of chlorine contact time are generally sufficient to deactivate giardia cysts. Satisfactory results can generally be obtained if a free chlorine residual (consisting of hypochlorous acid and hypochlorite ions) of 0.2 to 0.5 mg/L can be maintained throughout the distribution system. Combined residuals, if use is approved by health authorities, should be 1.0 to 2.0 mg/L at distant points in the distribution system.

Excess chlorine can be removed with a reducing agent, usually referred to as *dechlor*. Sodium dioxide and sodium bisulfate (metabisulfate) are used for this purpose. Aeration also reduces chlorine content, as does contact with activated charcoal.

Example 26.5

The flow rate through a treatment plant is 2 MGD (7.5 ML/day). The hypochlorite ion (OCl^-) dose is 20 mg/L as substance. The purity of calcium hypochlorite, $Ca(OCl)_2$, is 97.5% as delivered. How many pounds of calcium hypochlorite are needed to treat the water?

SI Solution

The approximate molecular weights for the components of calcium hypochlorite are

Ca:			40.1
O:	(2)(16)	=	32.0
Cl:	(2)(35.5)	=	70.0
	total		142.1

The fraction of available chlorine in the form of the hypochlorite ion is

$$\frac{32.0 + 70.0}{142.1} = 0.718$$

Use the standard dose equation with adjustments for both purity and availability.

$$F_{\text{kg/day}} = \frac{D_{\text{mg/L}} Q_{\text{ML/day}}}{P}$$

$$= \frac{\left(20\ \frac{\text{mg}}{\text{L}}\right)\left(7.5\ \frac{\text{ML}}{\text{day}}\right)}{(0.975)(0.718)}$$

$$= 214\ \text{kg/day}$$

Customary U.S. Solution

The approximate molecular weights for the components of calcium hypochlorite are

Ca:			40.1
O:	(2)(16)	=	32.0
Cl:	(2)(35.5)	=	70.0
	total		142.1

The fraction of available chlorine in the form of the hypochlorite ion is

$$\frac{32.0 + 70.0}{142.1} = 0.718$$

Use the standard dose equation with adjustments for both purity and availability.

$$F_{\text{lbm/day}} = \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{P}$$

$$= \frac{\left(20\ \frac{\text{mg}}{\text{L}}\right)(2\ \text{MGD})\left(8.345\ \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{(0.975)(0.718)}$$

$$= 477\ \text{lbm/day}$$

37. ADVANCED OXIDATION PROCESSES

Alternatives to chlorination have become necessary since THMs were traced to the chlorination process. These alternatives are categorized as *advanced oxidation processes* (AOPs).

Both bromine and iodine have properties similar to chlorine and can be used for disinfection. They are seldom used because they are relatively costly and produce their own disinfection by-products.

Chlorine dioxide (ClO_2) is manufactured at the water treatment plant from chlorine and sodium chlorite. Its ionization by-products (chlorite and chlorate) and high cost have limited its use.

Ozone is used extensively throughout the world, though not in large quantities in the United States. Ozone is a more powerful disinfectant than chlorine. Ozone can be used alone or (in several developing technologies) in conjunction with hydrogen peroxide. Ozone is generated on-site by running high voltage electricity through dry air or pure oxygen. Gases (oxygen and unused ozone) developing during ozonation must be collected and destroyed in an ozone-destruct unit to ensure that no ozone escapes into the atmosphere.

Ultraviolet radiation is effective in disinfecting shallow (e.g., less than 10 cm) bodies of water. Its primary disadvantages are cost and the absence of any residual disinfection for downstream protection.

38. CHLORAMINATION

Before leaving the plant, treated water may be *chloraminated.* This step ensures lasting disinfection by providing a residual level of chloramines, protecting the water against bacteria regrowth as it travels through the distribution system.

39. DEMINERALIZATION AND DESALINATION

Demineralization and desalination (*salt water conversion*) are required when only brackish water supplies are available.[20] These processes are carried out in distillation, electrodialysis, ion exchange, and membrane processes.

Distillation is a process whereby the raw water is vaporized, leaving the salt and minerals behind. The water vapor is reclaimed by condensation. Distillation cannot be used to economically provide large quantities of water.

Reverse osmosis is the least costly and most attractive membrane demineralization process. A thin membrane separates two solutions of different concentrations. Pore size is smaller (0.0001 to 0.001 μm) than with ultrafilter membranes (Sec. 24), as salt ions are not permitted to pass through. Typical large-scale osmosis units operate at 150 to 500 psi (1.0 to 5.2 MPa).[21]

Nanofiltration is similar to ultrafiltration and reverse osmosis, with pore size (0.001 μm) and operating pressure (75 to 250 psig; 0.5 to 1.7 MPa) intermediate between the two. Nanofilters are commonly referred to as *softening membranes.*

In *electrodialysis*, positive and negative ions flow through selective membranes under the influence of an induced electrical current. Unlike pressure-driven filtration processes, however, the ions (not the water molecules) pass through the membrane. The ions removed from the water form a concentrate stream that is discarded.

The *ion exchange* (Sec. 31) process is an excellent solution to demineralization and desalination.

40. WATER DEMAND

Normal water demand is specified in gallons per capita day (gpcd)—the average number of gallons used by each person each day. This is referred to as *average annual daily flow* (AADF) if the average is taken over a period of a year. Residential (i.e., domestic), commercial, industrial, and public uses all contribute to normal water demand, as do waste and unavoidable loss.[22]

As Table 26.4 illustrates, an AADF of 165 gpcd (625 Lpcd) is a typical minimum for planning purposes. If large industries are present (e.g., canning, steel making, automobile production, and electronics), then their special demand requirements must be added.

Table 26.4 *Annual Average Water Requirements*[a]

	demand	
use	gpcd	Lpcd
residential	75 to 130	284 to 490
commercial and industrial	70 to 100	265 to 380
public	10 to 20	38 to 80
loss and waste	10 to 20	38 to 80
totals	165 to 270	625 to 1030

(Multiply gpcd by 3.79 to obtain Lpcd.)
[a]exclusive of fire fighting requirements

Water demand varies with the time of day and season. Each community will have its own demand distribution curve. Table 26.5 gives typical multipliers, M, that might be used to estimate instantaneous demand from the average daily flow.

$$Q_{\text{instantaneous}} = M(\text{AADF}) \qquad 26.51$$

Table 26.5 *Typical Demand Multipliers (to be used with average annual daily flow)*

period of usage	multiplier, M
maximum daily	1.5 to 1.8
maximum hourly	2.0 to 3.0
early morning	0.25 to 0.40
noon	1.5 to 2.0
winter	0.80
summer	1.30

[20]In the United States, Florida and Arizona are leaders in desalinization installations. Potable water is routinely made from sea water in the Middle East.

[21]Membrane processes operate in a *fixed flux condition.* In order to keep the yield constant over time, the pressure must be constantly increased in order to compensate for the effects of fouling and compaction. Fouling by inorganic substances and biofilms is the biggest problem with membranes.

[22]"Public" use includes washing streets, flushing water and sewer mains, flushing fire hydrants, filling public fountains, and fighting fires.

Per capita demand must be multiplied by the population to obtain the total system demand. Since a population can be expected to change in number, a supply system must be designed to handle the water demand for a reasonable amount of time into the future. Several methods can be used for estimating future demand, including mathematical, comparative, and correlative methods. Various assumptions can be made for mathematical predictions, including uniform growth rate (same as straight-line extrapolation) and constant percentage growth rate. (In the case of decreasing population, the "growth" rate would be negative.)

Economic aspects will dictate the number of years of future capacity that are installed. Excess capacities of 25% for large systems and 50% for small systems are typically built into the system initially.

41. FIRE FIGHTING DEMAND

The Insurance Services Office (ISO) has specified that the *needed fire flow* (NFF) for 1- and 2-family dwellings not exceeding 2 stories in height should be 1500 gpm (95 L/s) for house separations 10 ft (3 m) or less, 1000 gpm (63 L/s) for separations 11 to 30 ft (3.3 to 9 m), 750 gpm (47 L/s) for separations 31 to 100 ft (9 to 30 m), and 500 gpm (31 L/s) for separations over 100 ft (30 m). For any other single building, the NFF will vary between 500 gpm (31 L/s) and 12,000 gpm (760 L/s).[23] Locations with this capability are given favorable insurance ratings.

A municipality must continue to service its domestic, commercial, and industrial customers during a fire. ISO has recommended that a fire system should be able to operate with the potable water system operating at the maximum 24 hr average daily rate plus fire for a minimum of 2 to 3 hr.

The needed fire flow proposed by the ISO for a particular building depends on the construction type, occupancy, height, floor area, adjacent spaces (communication), and exposure. The basic needed fire flow for a particular building is given by Eq. 26.52. The needed fire flow is obtained from Eq. 26.52 after adjusting for occupancy, exposure, and communication.[24]

$$Q_{\text{gpm}} = 18F\sqrt{A_{\text{ft}^2}} \qquad 26.52$$

In Eq. 26.52, F is a constant that depends on construction: 1.5 for wood frame (Class 1), 1.0 for ordinary (joisted masonry) construction (Class 2), 0.8 for noncombustible (masonry) construction (Classes 3 and 4), and 0.6 for fire-resistant construction (Classes 5 and 6). The *effective area*, A, includes all stories in the building except for the basement. Special rules are used to find the area for multistory, fire-resistant structures, buildings with various fire loadings, and buildings with sprinkler systems. Q is rounded to the nearest 250 gpm (16 L/s), but it should not be less than 500 gpm (31 L/s) or more than 6000 gpm (380 L/s) for any single-story building or any Class 3, 4, 5, or 6 building, or 8000 gpm (500 L/s) for any Class 1 or 2 building.

In estimating the water requirements for fire fighting on a population basis, the American Insurance Association has recommended Eq. 26.53. The population, P, is expressed in thousands of people.

$$Q_{\text{gpm}} = 1020\sqrt{P}\left(1 - 0.01\sqrt{P}\right) \qquad 26.53$$

Fire hydrants are generally spaced at a distance of 1000 ft (300 m) or closer. They are ordinarily located near street corners where use from four directions is possible. The actual separation of hydrants can be specified in building codes, local ordinances, and other published standards.

42. STORAGE AND DISTRIBUTION

Water is stored to provide water pressure, equalize pumping rates, equalize supply and demand over periods of high consumption, provide surge relief, and furnish water during fires and other emergencies when power is disrupted. Storage may also serve as part of the treatment process, either by providing increased detention time or by blending water supplies to obtain a desired concentration.

Several methods are used to distribute water depending on terrain, economics, and other local conditions. *Gravity distribution* is used when a lake or reservoir is located significantly higher in elevation than the population.

Distribution from *pumped storage* is the most common option when gravity distribution cannot be used. Excess water is pumped during periods of low hydraulic and electrical demands (usually at night) into elevated storage. During periods of high consumption, water is drawn from the storage. With pumped storage, pumps are able to operate at a uniform rate and near their rated capacity most of the time.

Using pumps without storage to force water directly into the mains is the least desirable option. Without storage, pumps and motors will not always be able to run in their most efficient ranges since they must operate during low, average, and peak flows. In a power outage, all water supply will be lost unless a backup power source comes online quickly or water can be obtained by gravity flow.

Water is commonly stored in surface and elevated tanks. The elevation of the water surface in the tank directly determines the distribution pressure. This elevation is controlled by an *altitude valve* that operates on the differential in pressure between the height of the water and

[23] A standard 1.125 in (29 mm) diameter smooth fire nozzle discharges approximately 250 gpm (16 L/s) of water.

[24] Source: *Fire Suppression Rating Schedule*, Insurance Services Office, copyright © 1980.

an adjustable spring-loaded pilot on the valve. Altitude valves are installed at ground level and, when properly adjusted, can maintain the water levels to within 4 in. Tanks must be vented to the atmosphere. Otherwise, a rapid withdrawal of water will create a vacuum that could easily cause the tank to collapse inward.

The preferred location of an elevated tank is on the opposite side of the high-consumption district from the pumping station. During periods of high water use, the district will be fed from both sides, reducing the loss of head in the mains below what would occur without elevated storage.

Equalizing the pumping rate during the day ordinarily requires storage of at least 15 to 20% of the maximum daily use. Storage for fires and emergencies is more difficult to determine. Fire storage is essentially dictated by building ordinances and insurance (i.e., economic benefits to the public). Private on-site storage volume for large industries may be dictated by local codes and ordinances.

43. WATER PIPE

Several types of pipe are used in water distribution depending on the flow rate, installed location (i.e., above or below ground), depth of installation, and surface surcharge. Pipes must have adequate strength to withstand external loads from backfill, traffic, and earth movement. They must have high burst strength to withstand internal pressure, a smooth interior surface to reduce friction, corrosion resistance, and tight joints to minimize loss. Once all other requirements have been satisfied, the choice of pipe material can be made on the basis of economics.

Asbestos-cement pipe was used extensively in the past. It has a smooth inner surface and is immune to galvanic corrosion. However, it has low flexural strength. *Concrete pipe* is durable, watertight, has a smooth interior, and requires little maintenance. It is manufactured in plain and reinforced varieties. *Cast-iron pipe* (ductile and gray varieties) is strong, offers long life, and is impervious. However, it has a high initial cost and is heavy (i.e., difficult to transport and install). It may need to be coated on the exterior and interior to resist corrosion of various types. *Steel pipe* offers a smooth interior, high strength, and high ductility, but it is susceptible to corrosion inside and out. The exterior and interior may both need to be coated for protection. *Plastic pipe* (ABS and PVC) has a smooth interior and is chemically inert, corrosion resistant, and easily transported and installed. However, it has low strength.

44. SERVICE PRESSURE

For ordinary domestic use, the minimum water pressure at the tap should be 25 to 40 psig (170 to 280 kPa). A minimum of 60 psig (400 kPa) at the fire hydrant is usually adequate, since that allows for up to a 20 psig (140 kPa) pressure drop in fire hoses. 75 psig (500 kPa) and higher is common in commercial and industrial districts. *Pressure regulators* can be installed if delivery pressure is too high.

45. WATER MANAGEMENT

Unaccounted-for water is the potable water that is produced at the water treatment plant but is not accounted for in billing. It includes known unmetered uses (such as fire fighting and hydrant flushing) and all unknown uses (e.g., from leaks, broken meters, theft, and illegal connections).

Unaccounted-for water can be controlled with proper attention to meter selection, master metering, leak detection, quality control (installation and maintenance of meters), control of system pressures, and accurate data collection.

Since delivery is under pressure, infiltration of groundwater into pipe joints is not normally an issue with distribution.

PRACTICE PROBLEMS

Plain Sedimentation

1. A settling tank has an overflow rate of 100,000 gal/ft^2-day. Water carrying sediment of various sizes enters the tank. The sediment has the following distribution of settling velocities.

settling velocity (ft/min)	mass fraction remaining
10.0	0.54
5.0	0.45
2.0	0.35
1.0	0.20
0.75	0.10
0.50	0.03

What is the gravimetric percentage of sediment removed?

(A) 32%
(B) 39%
(C) 47%
(D) 55%

The answer is (C).

2. A spherical sand particle has a specific gravity of 2.6 and a diameter of 1 mm. What is the settling velocity?

(A) 0.2 ft/sec
(B) 0.7 ft/sec
(C) 1.1 ft/sec
(D) 1.6 ft/sec

The answer is (B).

3. A mechanically cleaned circular clarifier is to be designed with the following characteristics.

flow rate	2.8 MGD
detention period	2 hr
surface loading	700 gal/ft^2-day

(a) What is the approximate diameter?

(A) 45 ft
(B) 60 ft
(C) 70 ft
(D) 90 ft

The answer is (C).

(b) What is the approximate depth?

(A) 6 ft
(B) 8 ft
(C) 12 ft
(D) 15 ft

The answer is (B).

(c) If the initial flow rate is reduced to 1.1 MGD, what is the surface loading?

(A) 190 gal/day-ft^2
(B) 230 gal/day-ft^2
(C) 250 gal/day-ft^2
(D) 280 gal/day-ft^2

The answer is (D).

(d) If the initial flow rate is reduced to 1.1 MGD, what is the average detention period?

(A) 4 hr
(B) 5 hr
(C) 6 hr
(D) 8 hr

The answer is (B).

4. (*Time limit: one hour*) A water treatment plant is designed to handle a total flow rate of 1.5 MGD. The current design includes two identical sedimentation basins with the following characteristics.

plan area	90 ft × 16 ft
depth	12 ft
total weir length	48 ft per basin
three-month sustained average low	70% of the design average daily flow
three-month sustained average high	200% of the design average daily flow

The basins must meet the following government standards.

minimum retention time	4.0 hrs
maximum weir load	20,000 gpd/ft
maximum velocity	0.5 ft/min

Do the basins meet the standards?

(A) Yes, specifications are met at both peak and low flows.
(B) No, specifications are not met at low flow.
(C) No, specifications are not met at high flow.
(D) No, specifications are not met at either high or low flow.

The answer is (C).

Mixing Physics

5. (*Time limit: one hour*) A flocculator tank with a volume of 200,000 ft^3 uses a paddle wheel to mix the coagulant in 60°F water. The operating characteristics are as follows.

mean velocity gradient	45 sec^{-1}
paddle drag coefficient	1.75
paddle tip velocity	2 ft/sec
relative water/paddle velocity	1.5 ft/sec

(a) What is the theoretical power required to drive the paddle?

(A) 12 hp
(B) 17 hp
(C) 60 hp
(D) 120 hp

The answer is (B).

(b) What is the drag force on the paddle?

(A) 450 lbf
(B) 910 lbf
(C) 5500 lbf
(D) 6400 lbf

The answer is (D).

(c) What is the required paddle area?

(A) 900 ft^2
(B) 1200 ft^2
(C) 1500 ft^2
(D) 1700 ft^2

The answer is (D).

Filtration

6. A water treatment plant has four square rapid sand filters. The flow rate is 4 gal/min-ft^2. Each filter has a treatment capacity of 600,000 gal/day. Each filter is backwashed once a day for 8 min. The rate of rise during washing is 24 in/min.

(a) What are the inside dimensions of each filter?

(A) 6 ft × 6 ft
(B) 8 ft × 8 ft
(C) 10 ft × 10 ft
(D) 12 ft × 12 ft

The answer is (C).

(b) What percentage of the filtered water is used for backwashing?

(A) 2%
(B) 4%
(C) 8%
(D) 10%

The answer is (A).

7. A water treatment plant has five identical rapid sand filters. Each is square in plan and has a capacity of 1.0 MGD. The application rate is 4 gal/min-ft^2, and the total wetted depth is 10 ft.

(a) What should be the cross-section dimensions of each filter?

(A) 7 ft × 7 ft
(B) 9 ft × 9 ft
(C) 10 ft × 10 ft
(D) 13 ft × 13 ft

The answer is (D).

(b) Each filter is backwashed every day for 5 min. The rate of rise of the backwash water is 2 ft/min. What percentage of the plant's filtered water will be used for backwashing?

(A) 1.3%
(B) 1.9%
(C) 2.4%
(D) 3.1%

The answer is (A).

Precipitation Softening

8. A town's water supply has the following ionic concentrations.

Al^{+++}	0.5 mg/L
Ca^{++}	80.2 mg/L
Cl^-	85.9 mg/L
CO_2	19 mg/L
CO_3^{--}	0
Fe^{++}	1.0 mg/L
Fl^-	0
HCO_3^-	185 mg/L
Mg^{++}	24.3 mg/L
Na^+	46.0 mg/L
NO_3^-	0
SO_4^{--}	125 mg/L

(a) What is the total hardness?

(A) 160 mg/L as $CaCO_3$
(B) 200 mg/L as $CaCO_3$
(C) 260 mg/L as $CaCO_3$
(D) 300 mg/L as $CaCO_3$

The answer is (D).

(b) How much slaked lime is required to combine with the carbonate hardness?

(A) 45 mg/L as substance
(B) 90 mg/L as substance
(C) 130 mg/L as substance
(D) 150 mg/L as substance

The answer is (D).

(c) How much soda ash is required to react with the noncarbonate hardness?

(A) none
(B) 15 mg/L as substance
(C) 35 mg/L as substance
(D) 60 mg/L as substance

The answer is (A).

9. A city's water supply contains the following ionic concentrations.

$Ca(HCO_3)_2$	137 mg/L as $CaCO_3$
$MgSO_4$	72 mg/L as $CaCO_3$
CO_2	0

(a) How much slaked lime is required to soften 1,000,000 gal of this water to a hardness of 100 mg/L if 30 mg/L of excess lime is used?

(A) 930 lbm
(B) 1200 lbm
(C) 1300 lbm
(D) 1700 lbm

The answer is (A).

(b) How much soda ash is required to soften 1,000,000 gal of this water to a hardness of 100 mg/L if 30 mg/L of excess lime is used?

(A) none
(B) 300 lbm
(C) 500 lbm
(D) 700 lbm

The answer is (A).

Zeolite Softening

10. The water described in Prob. 9 is to be softened using a zeolite process with the following characteristics: exchange capacity, 10,000 grains/ft^3; and salt requirement, 0.5 lbm per 1000 grains hardness removed. How much salt is required to soften the water to 100 mg/L hardness?

(A) 700 lbm/MG
(B) 1800 lbm/MG
(C) 2500 lbm/MG
(D) 3200 lbm/MG

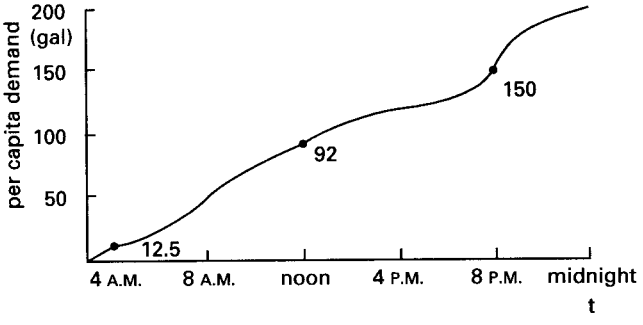
The answer is (D).

11. The hardness of water from an underground aquifer is to be reduced from 245 mg/L to 80 mg/L using a zeolite process. The volumetric flow rate is 20,000 gal/day. The process has the following characteristics: resin exchange capacity, 20,000 grains/ft^3; and zeolite volume, 2 ft^3.

(a) What fraction of the water is bypassed around the process?

(A) 0.15
(B) 0.33
(C) 0.67
(D) 0.85

The answer is (B).



(b) What is the time between regenerations of the softener?

(A) 5 hr
(B) 16 hr
(C) 24 hr
(D) 30 hr

The answer is (A).

Demand

12. (*Time limit: one hour*) An area is expected to attain a population of 40,000 in 20 years. The cumulative per capita water demand for a peak day in the area is shown in the following diagram.

(a) What is the total per capita demand for a peak day?

(A) 160 gal
(B) 200 gal
(C) 240 gal
(D) 290 gal

The answer is (B).

(b) Assuming uniform operation over 24 hours, what storage volume is required in the treatment plant for all uses, including fire fighting demand?

(A) 1.1 MG
(B) 2.7 MG
(C) 3.2 MG
(D) 5.5 MG

The answer is (C).

(c) Assume that the pumping station runs uniformly from 4 A.M. until 8 A.M. to fill the storage tanks for the day. What storage is required to meet all uses, including fire fighting?

(A) 3.2 MG
(B) 3.8 MG
(C) 5.5 MG
(D) 8.7 MG

The answer is (D).

13. The water supply for a town of 15,000 people is taken from a river. The average consumption is 110 gpcd. The water has the following characteristics.

turbidity	20 to 100 NTU (varies)
total hardness	less than 60 mg/L as $CaCO_3$
coliform count	200 to 1000 per 100 mL (varies)

(a) What capacity should the distribution and treatment system have?

(A) 6000 gpm
(B) 7500 gpm
(C) 9500 gpm
(D) 12,000 gpm

The answer is (B).

(b) If the application rate is 4 gal/min-ft^2, what total filter area is required?

(A) 580 ft^2
(B) 720 ft^2
(C) 910 ft^2
(D) 1100 ft^2

The answer is (A).

(c) Is softening required?

(A) No, 60 mg/L is soft water.
(B) No, softening would interfere with turbidity removal.
(C) Yes, the turbidity and coliform counts would also benefit.
(D) Yes, all municipal water should be softened.

The answer is (A).

(d) If a chlorine dose of 2 mg/L is required to obtain the desired chlorine residual, how much chlorine is required every 24 hours?

(A) 15 lbm
(B) 22 lbm
(C) 28 lbm
(D) 32 lbm

The answer is (C).

Practice Problems 27-6

1. MICROORGANISMS

Microorganisms occur in untreated water and represent a potential human health risk if they enter the water supply. Microorganisms include viruses, bacteria, fungi, algae, protozoa, worms, rotifers, and crustaceans.

Microorganisms are organized into three broad groups based upon their structural and functional differences. The groups are called *kingdoms.* The three kingdoms are animals (rotifers and crustaceans), plants (mosses and ferns), and *Protista* (bacteria, algae, fungi, and protozoa). Bacteria and protozoa of the kingdom *Protista* make up the major groups of microorganisms in the biological system that is used in secondary treatment of wastewater.

2. PATHOGENS

Many infectious diseases in humans or animals are caused by organisms categorized as *pathogens.* Pathogens are found in fecal wastes that are transmitted and transferred through the handling of wastewater. Pathogens will proliferate in areas where sanitary disposal of feces is not adequately practiced and where contamination of water supply from infected individuals is not properly controlled. The wastes may also be improperly discharged into surface waters, making the water *nonpotable* (unfit for drinking). Certain shellfish can become toxic when they concentrate pathogenic organisms in their tissues, increasing the toxic levels much higher than the levels in the surrounding waters.

Organisms that are considered to be pathogens include bacteria, protozoa, viruses, and helminths (worms). Table 27.1 lists potential waterborne diseases, the causative organisms, and the typical infection sources.

Not all microorganisms are considered pathogens. Some microorganisms are exploited for their usefulness in wastewater processing. Most wastewater engineering (and an increasing portion of environmental engineering) involves designing processes and operating facilities that utilize microorganisms to destroy organic and inorganic substances.

3. MICROBE CATEGORIZATION

Carbon is the basic building block for cell synthesis, and it is prevalent in large quantities in wastewater. Wastewater treatment converts carbon into microorganisms that are subsequently removed from the water by settling. Therefore, the growth of organisms that use organic material as energy is encouraged.

If a microorganism uses organic material as a carbon supply, it is *heterotrophic. Autotrophs* require only carbon dioxide to supply their carbon needs. Organisms that rely only on the sun for energy are called *phototrophs. Chemotrophs* extract energy from organic or inorganic oxidation/reduction (redox) reactions. *Organotrophs* use organic materials, while *lithotrophs* oxidize inorganic compounds.

Most microorganisms in wastewater treatment processes are bacteria. Conditions in the treatment plant are readjusted so that chemoheterotrophs predominate.

Each species of bacteria reproduces most efficiently within a limited range of temperatures. Four temperature ranges are used to classify bacteria. Those bacteria that grow best below 86°F (20°C) are called *psychrophiles* (i.e., are *psychrophilic*, also known as *cryophilic*). *Mesophiles* (i.e., *mesophilic bacteria*) grow best at temperatures in a range starting around 68°F (20°C) and ending around 113°F (45°C). Between 113°F (45°C) and 140°F (60°C), the *thermophiles* (*thermophilic bacteria*) grow best. Above 140°F (60°C), *stenothermophiles* grow best.

Table 27.1 *Potential Pathogens*

name of organism	major disease	source
Bacteria		
Salmonella typhi	typhoid fever	human feces
Salmonella paratyphi	paratyphoid fever	human feces
other *Salmonella*	salmonellosis	human/animal feces
Shigella	bacillary dysentery	human feces
Vibrio cholerae	cholera	human feces
Enteropathogenic coli	gastroenteritis	human feces
Yersinia enterocolitica	gastroenteritis	human/animal feces
Campylobacter jejuni	gastroenteritis	human/animal feces
Legionella pneumophila	acute respiratory illness	thermally enriched waters
Mycobacterium	tuberculosis	human respiratory exudates
other *Mycobacteria*	pulmonary illness	soil and water
Opportunistic bacteria	variable	natural waters
Enteric Viruses/Enteroviruses		
Polioviruses	poliomyelitis	human feces
Coxsackieviruses A	aseptic meningitis	human feces
Coxsackieviruses B	aseptic meningitis	human feces
Echoviruses	aseptic meningitis	human feces
other *Enteroviruses*	encephalitis	human feces
Reoviruses	upper respiratory and gastrointestinal illness	human/animal feces
Rotaviruses	gastroenteritis	human feces
Adenoviruses	upper respiratory and gastrointestinal illness	human feces
Hepatitis A virus	infectious hepatitis	human feces
Norwalk and related gastrointestinal viruses	gastroenteritis	human feces
Fungi		
Aspergillus	ear, sinus, lung, and skin infections	airborne spores
Candida	yeast infections	various
Protozoa		
Acanthamoeba castellani	amoebic meningoencephalitis	soil and water
Balantidium coli	balantidosis (dysentery)	human feces
Cryptosporidium[a]	cryptosporidiosis	human/animal feces
Entamoeba histolytica	amoebic dysentery	human feces
Giardia lamblia	giardiasis (gastroenteritis)	human/animal feces
Naegleria fowleri	amoebic meningoencephalitis	soil and water
Algae (blue-green)		
Anabaena flos-aquae	gastroenteritis (possible)	natural waters
Microcystis aeruginosa	gastroenteritis (possible)	natural waters
Alphanizomenon flos-aquae	gastroenteritis (possible)	natural waters
Schizothrix calciola	gastroenteritis (possible)	natural waters
Helminths (intestinal parasites/worms)		
Ascaris lumbricoides (roundworm)	digestive disturbances	ingested worm eggs
E. vericularis (pinworm)	any part of the body	ingested worm eggs
Hookworm	pneumonia, anemia	ingested worm eggs
Threadworm	abdominal pain, nausea, weight loss	ingested worm eggs
T. trichiuro (whipworm)	trichinosis	ingested worm eggs
Tapeworm	digestive disturbances	ingested worm eggs

[a]Disinfectants have little effect on *Cryptosporidia.* Most large systems now use filtration, the most effective treatment to date against *Cryptosporidia.*

Because most reactions proceed slowly at these temperatures, cells use *enzymes* to speed up the reactions and control the rate of growth. Enzymes are proteins, ranging from simple structures to complex conjugates, and are specialized for the reactions they catalyze.

The temperature ranges are qualitative and somewhat subjective. The growth range of facultative thermophiles extends from the thermophilic range into the mesophilic range. Bacteria will grow in a range of temperatures and will survive at a very large range of temperatures. *E. coli*, for example, is classified as a mesophile. It grows best at temperatures between 68°F (20°C) and 122°F (50°C) but can continue to reproduce at temperatures down to 32°F (0°C).

Nonphotosynthetic bacteria are classified into two heterotrophic and autotrophic groups depending on their sources of nutrients and energy. *Heterotrophs* use organic matter as both an energy source and a carbon source for synthesis. Heterotrophs are further subdivided into groups depending on their behavior toward free oxygen: aerobes, anaerobes, and facultative bacteria. *Obligate aerobes* require free dissolved oxygen while they decompose organic matter to gain energy for growth and reproduction. Obligate anaerobes oxidize organics in the complete absence of dissolved oxygen by using the oxygen bound in other compounds, such as nitrate and sulfate. *Facultative bacteria* comprise a group that uses free dissolved oxygen when available but that can also behave anaerobically in the absence of free dissolved oxygen (i.e., *anoxic conditions*). Under anoxic conditions, a group of facultative anaerobes, called *denitrifiers*, utilizes nitrites and nitrates instead of oxygen. Nitrate nitrogen is converted to nitrogen gas in the absence of oxygen. This process is called *anoxic denitrification.*

Autotrophic bacteria (*autotrophs*) oxidize inorganic compounds for energy, use free oxygen, and use carbon dioxide as a carbon source. Significant members of this group are the *Leptothrix* and *Crenothrix* families of *iron bacteria.* These have the ability to oxidize soluble ferrous iron into insoluble ferric iron. Because soluble iron is often found in well waters and iron pipe, these bacteria deserve some attention. They thrive in water pipes where dissolved iron is available as an energy source and bicarbonates are available as a carbon source. As the colonies die and decompose, they release foul tastes and odors and have the potential to cause staining of porcelain or fabrics.

4. VIRUSES

Viruses are parasitic organisms that pass through filters that retain bacteria, can only be seen with an electron microscope, and grow and reproduce only inside living cells, but they can survive outside the host. They are not cells, but particles composed of a protein sheath surrounding a nucleic-acid core. Most viruses of interest in water supply range in size from 10 to 25 nm.

The viron particles invade living cells and the viral genetic material redirects cell activities toward production of new viral particles. A large number of viruses are released to infect other cells when the infected cell dies. Viruses are host-specific, attacking only one type of organism.

There are more than 100 types of human enteric viruses. Those of interest in drinking water are *Hepatitis A*, *Norwalk*-type viruses, *Rotaviruses*, *Adenoviruses*, *Enteroviruses*, and *Reoviruses.*

5. BACTERIA

Bacteria are microscopic plants having round, rodlike, spiral or filamentous single-celled or noncellular bodies. They are often aggregated into colonies. Bacteria use soluble food and reproduce through binary fission. Most bacteria are not pathogenic to humans, but they do play a significant role in the decomposition of organic material and can have an impact on the aesthetic quality of water.

6. FUNGI

Fungi are aerobic, multicellular, nonphotosynthetic, heterotrophic, eukaryotic protists. Most fungi are saprophytes that degrade dead organic matter. Fungi grow in low-moisture areas, and they are tolerant of low-pH environments. Fungi release carbon dioxide and nitrogen during the breakdown of organic material.

Fungi are obligate aerobes that reproduce by a variety of methods including fission, budding, and spore formation. They form normal cell material with one-half the nitrogen required by bacteria. In nitrogen-deficient wastewater, they may replace bacteria as the dominant species.

7. ALGAE

Algae are autotrophic, photosynthetic organisms (*photoautotrophs*) and may be either unicellular or multicellular. They take on the color of the pigment that is the catalyst for photosynthesis. In addition to chlorophyll (green), different algae have different pigments, such as carotenes (orange), phycocyanin (blue), phycoerythrin (red), fucoxanthin (brown), and xanthophylls (yellow).

Algae derive carbon from carbon dioxide and bicarbonates in water. The energy required for cell synthesis is obtained through photosynthesis. Algae utilize oxygen for respiration in the absence of light. Algae and bacteria have a symbiotic relationship in aquatic systems, with the algae producing oxygen used by the bacterial population.

In the presence of sunlight, the photosynthetic production of oxygen is greater than the amount used in respiration. At night algae use up oxygen in respiration.

If the daylight hours exceed the night hours by a reasonable amount, there is a net production of oxygen. Excessive algal growth (*algal blooms*) can result in supersaturated oxygen conditions in the daytime and anaerobic conditions at night.

Some algae cause tastes and odors in natural water. While they are not generally considered pathogenic to humans, algae do cause turbidity, and turbidity provides a residence for microorganisms that are pathogenic.

8. PROTOZOA

Protozoa are single-celled animals that reproduce by *binary fission* (dividing in two). Most are aerobic chemoheterotrophs (i.e., *facultative heterotrophs*). Protozoa have complex digestive systems and use solid organic matter as food, including algae and bacteria. Therefore, they are desirable in wastewater effluent because they act as polishers in consuming the bacteria.

Flagellated protozoa are the smallest protozoans. The *flagella* (long hairlike strands) provide motility by a whiplike action. Amoeba move and take in food through the action of a mobile protoplasm. Free-swimming protozoa have *cilia*, small hairlike features, used for propulsion and gathering in organic matter.

9. WORMS AND ROTIFERS

A number of worms and rotifers are of importance to water quality. *Rotifers* are aerobic chemoheterotrophs that prey on bacteria. Many *worms* are aquatic parasites. *Flatworms* of the class *Trematoda* are known as *flukes*, and the *Cestoda* are tapeworms. *Nemotodes* of public health concern are *Trichinella*, which causes trichinosis; *Necator*, which causes pneumonia; *Ascaris*, which is common roundworm; and *Filaria*, which causes filariasis.

10. CRUSTACEANS

Both *rotifers* and *crustaceans* are aerobic, multicellular chemoheterotrophs. The rotifer derives its name from the apparent rotating motion of two sets of cilia on its head. The cilia provide mobility and a mechanism for catching food. Rotifers consume bacteria and small particles of organic matter.

Crustaceans, such as mussels and clams, are characterized by a shell structure. They are aerobic chemoheterotrophs that feed on bacteria and algae. They are a source of food for fish and are not found in wastewater treatment systems to any extent, except in underloaded lagoons. Their presence is indicative of a high level of dissolved oxygen and a very low level of organic matter.

Macrofouling is a term referring to infestation of water inlets and outlets by clams and mussels. *Zebra mussels*, accidentally introduced into the United States in 1986, are particularly troublesome for several reasons. First, young mussels are microscopic, easily passing through intake screens. Second, they attach to anything, even other mussels, producing thick colonies. Third, adult mussels quickly sense some biocides, most notably those that are halogen-based (including chlorine), quickly closing and remaining closed for days or weeks.

The use of biocides in the control of zebra mussels is controversial. Chlorination is a successful treatment that is recommended with some caution since it results in increased toxicity, affecting other species and THM production. Nevertheless, an ongoing biocide program aimed at pre-adult mussels, combined with slippery polymer-based surface coatings, is probably the best approach at prevention. Once a pipe is colonized, mechanical removal by scraping or water blasting is the only practical option.

11. INDICATOR ORGANISMS

The techniques for comprehensive bacteriological examination for pathogens are complex and time-consuming. Isolating and identifying specific pathogenic microorganisms is a difficult and lengthy task. Many of these organisms require sophisticated tests that take several days to produce results. Because of these difficulties, and also because the number of pathogens relative to other microorganisms in water can be very small, *indicator organisms* are used as a measure of the quality of the water. The primary function of an indicator organism is to provide evidence of recent fecal contamination from warm-blooded animals.

Characteristics of a good indicator organism are: (a) The indicator is always present when the pathogenic organism of concern is present. It is absent in clean, uncontaminated water. (b) The indicator is present in fecal material in large numbers. (c) The indicator responds to natural environmental conditions and to treatment processes in a manner similar to the pathogens of interest. (d) The indicator is easy to isolate, identify, and enumerate. (e) The ratio of indicator to pathogen should be high. (f) The indicator and pathogen should come from the same source (e.g., gastrointestinal tract).

While there are several microorganisms that meet these criteria, *total coliform* and *fecal coliform* are the indicators generally used. *Total coliform* refers to the group of aerobic and facultatively anaerobic, gram-negative, nonspore-forming, rod-shaped bacteria that ferment lactose with gas formation within 48 hr at 662°F (350°C). This encompasses a variety of organisms, mostly of intestinal origin, including *Escherichia coli* (*E. coli*), the most numerous facultative bacterium in the feces of warm-blooded animals. Unfortunately, this group also includes *Enterobacter, Klebsiella,* and *Citrobacter*, which are present in wastewater but can be derived from other environmental sources such as soil and plant materials.

Fecal coliforms are a subgroup of the total coliforms that come from the intestines of warm-blooded animals. They are measured by running the standard total coliform fermentation test at an elevated temperature of 112°F (44.5°C), providing a means to distinguish false positives in the total coliform test.

Results of fermentation tests are reported as a *most probable number* (MPN) *index*. This is an index of the number of coliform bacteria that, more probably than any other number, would give the results shown by the laboratory examination; it is not an actual enumeration.

12. METABOLISM/METABOLIC PROCESSES

Metabolism is a term given to describe all chemical activities performed by a cell. The cell uses *adenosine triphosphate* (ATP) as the principle energy currency in all processes. Those processes that allow the bacterium to synthesize new cells from the energy stored within its body are said to be *anabolic*. All biochemical processes in which cells convert substrate into useful energy and waste products are said to be *catabolic*.

13. DECOMPOSITION OF WASTE

Decomposition of waste involves oxidation/reduction reactions and is classified as aerobic or anaerobic. The type of electron acceptor available for catabolism determines the type of decomposition used by a mixed culture of microorganisms. Each type of decomposition has peculiar characteristics that affect its use in waste treatment.

14. AEROBIC DECOMPOSITION

Molecular oxygen (O_2) must be present as the terminal electron acceptor in order for decomposition to proceed by aerobic oxidation. As in natural water bodies, the dissolved oxygen content is measured. When oxygen is present, it is the only terminal electron acceptor used. Hence, the chemical end products of decomposition are primarily carbon dioxide, water, and new cell material as demonstrated by Table 27.2. Odoriferous, gaseous end products are kept to a minimum. In healthy natural water systems, aerobic decomposition is the principal means of self-purification.

A wider spectrum of organic material can be oxidized by aerobic decomposition than by any other type of decomposition. Because of the large amount of energy released in aerobic oxidation, most aerobic organisms are capable of high growth rates. Consequently, there is a relatively large production of new cells in comparison with the other oxidation systems. This means that more biological sludge is generated in aerobic oxidation than in the other oxidation systems.

Aerobic decomposition is the preferred method for large quantities of dilute ($BOD_5 < 500$ mg/L) wastewater because decomposition is rapid and efficient and has a low odor potential. For high-strength wastewater ($BOD_5 > 1000$ mg/L), aerobic decomposition is not suitable because of the difficulty in supplying enough oxygen and because of the large amount of biological sludge that is produced.

15. ANOXIC DECOMPOSITION

Some microorganisms will use nitrates in the absence of oxygen needed to oxidize carbon. The end products from such *denitrification* are nitrogen gas, carbon dioxide, water, and new cell material. The amount of energy made available to the cell during denitrification is about the same as that made available during aerobic decomposition. The production of cells, although not as high as in aerobic decomposition, is relatively high.

Table 27.2 *Waste Decomposition End Products*

	representative end products		
substrates	aerobic decomposition	anoxic decomposition	anaerobic decomposition

Denitrification is of importance in wastewater treatment when nitrogen must be removed. In such cases, a special treatment step is added to the conventional process for removal of carbonaceous material. One other important aspect of denitrification is in final clarification of the treated wastewater. If the final clarifier becomes anoxic, the formation of nitrogen gas will cause large masses of sludge to float to the surface and escape from the treatment plant into the receiving water. Thus, it is necessary to ensure that anoxic conditions do not develop in the final clarifier.

16. ANAEROBIC DECOMPOSITION

In order to achieve anaerobic decomposition, molecular oxygen and nitrate must not be present as terminal electron acceptors. Sulfate, carbon dioxide, and organic compounds that can be reduced serve as terminal electron acceptors. The reduction of sulfate results in the production of hydrogen sulfide (H_2S) and a group of equally odoriferous organic sulfur compounds called *mercaptans.*

The anaerobic decomposition of organic matter, also known as *fermentation*, generally is considered to be a two-step process. In the first step, complex organic compounds are fermented to low molecular weight *fatty acids* (*volatile acids*). In the second step, the organic acids are converted to methane. Carbon dioxide serves as the electron acceptor.

Anaerobic decomposition yields carbon dioxide, methane, and water as the major end products. Additional end products include ammonia, hydrogen sulfide, and mercaptans. As a consequence of these last three compounds, anaerobic decomposition is characterized by a malodorous stench.

Because only small amounts of energy are released during anaerobic oxidation, the amount of cell production is low. Thus, sludge production is correspondingly low. Wastewater treatment based on anaerobic decomposition is used to stabilize sludges produced during aerobic and anoxic decomposition.

Direct anaerobic decomposition of wastewater generally is not feasible for dilute waste. The optimum growth temperature for the anaerobic bacteria is at the upper end of the mesophilic range. Thus, to get reasonable biodegradation, the temperature of the culture must first be elevated. For dilute wastewater, this is not practical. For concentrated wastes (BOD_5 > 1000 mg/L), anaerobic digestion is quite appropriate.

17. FACTORS AFFECTING DISEASE TRANSMISSION

Waterborne disease transmission is influenced by the latency, persistence, and quantity (dose) of the pathogens. *Latency* is the period of time between excretion of a pathogen and its becoming infectious to a new host. *Persistence* is the length of time that a pathogen remains viable in the environment outside a human host. The *infective dose* is the number of organisms that must be ingested to result in disease.

18. AIDS

Acquired immunodeficiency syndrome (AIDS) is caused by the *human immunodeficiency virus* (HIV). HIV is present in virtually all body excretions of infected persons, and therefore, is present in wastewater. Present research, statistics, and available information indicates that the risk of contracting AIDS through contact with wastewater or working at a wastewater plant is nil. This is based on the following facts.

- HIV is relatively weak and does not remain viable for long periods of time in harsh environments (e.g., wastewater).
- HIV is quickly inactivated by alcohol, chlorine, and exposure to air. The chlorine concentration present in water used to flush the toilet would probably deactivate HIV.
- HIV that survives disinfection would be too dilute to be infectious.
- HIV replicates in white blood cells, not in the human intestinal tract, and, therefore, would not reproduce in wastewater.
- There is no evidence that HIV can be transmitted through water, air, food, or contact. HIV must enter the bloodstream directly, through a wound. It cannot enter through unbroken skin or through respiration.
- HIV is less infectious than the hepatitis virus.
- There are no reported AIDS cases linked to occupational exposure in wastewater collection and treatment.

PRACTICE PROBLEMS

1. (*Time limit: one hour*) A fresh wastewater sample is taken containing nitrate ions, sulfate ions, and dissolved oxygen, and it is placed in a sealed jar absent of air.

(a) What is the sequence of oxidation of the compounds?

(A) nitrate, dissolved oxygen, and then sulfate
(B) sulfate, nitrate, and then dissolved oxygen
(C) dissolved oxygen, nitrate, and then sulfate
(D) none of the above

The answer is (C).

(b) Obnoxious odors will
(A) appear in the sample when the dissolved oxygen is exhausted.
(B) appear in the sample when the dissolved oxygen and nitrates are exhausted.
(C) appear in the sample when the dissolved oxygen, nitrate, and sulfate are exhausted.
(D) not appear.

The answer is (B).

(c) Bacteria will convert ammonia to nitrate if the bacteria are
(A) phototropic.
(B) autotropic.
(C) thermophilic.
(D) obligate anaerobes.

The answer is (B).

(d) Bacteria will reduce nitrate to nitrogen gas if the bacteria are
(A) obligate heterotropic.
(B) obligate anaerobic.
(C) facultative heterotropic.
(D) facultative anaerobic.

The answer is (C).

(e) A bacteriophage is a
(A) bacterial enzyme.
(B) virus that infects bacteria.
(C) mesophilic organism.
(D) virus that stimulates bacterial growth.

The answer is (B).

(f) Algal growth in the wastewater
(A) will be inhibited when the dissolved oxygen is exhausted.
(B) will be inhibited when toxins are also found in the solution.
(C) will be inhibited when toxins are found in the solution or when the dissolved oxygen is exhausted.
(D) cannot be inhibited by chemical means.

The answer is (C).

(g) Algal growth, in the presence of nitrifying bacteria in the wastewater sample,
(A) will occur if the sample is exposed to sunlight.
(B) will occur if inorganic nutrients are absent.
(C) will occur if inorganic nutrients are present.
(D) cannot occur.

The answer is (B).

(h) The addition of protozoa to the wastewater will
(A) not change the wastewater's biochemical composition.
(B) increase the growth of algae in wastewater.
(C) increase the growth of bacteria in wastewater.
(D) decrease the growth of algae and bacteria in the wastewater.

The answer is (D).

(i) Coliform bacteria in wastewater from human, animal, or soil sources
(A) can be distinguished in the multiple-tube fermentation test.
(B) can be categorized into only two groups: human/animal and soil.
(C) can be distinguished if multiple-tube fermentation and Escherichia coli (EC) tests are both used.
(D) cannot be distinguished.

The answer is (B).

(j) Under what specific condition would a presence-absence (P-A) coliform test be used on this sample?
(A) if the sample contains known pathogens
(B) when multiple-tube fermentation indicates positive dilution in a presumptive test
(C) when multiple-tube fermentation indicates negative dilution in a presumptive test
(D) if the sample will be used as drinking water

The answer is (D).

2. A waste stabilization pond will be used in a municipal wastewater treatment system.

(a) Explain the function of bacteria and algae in the stabilization pond's application.

(b) Explain why algae would be a problem if it were present in the discharge from the pond.

(c) Define mechanisms that could be utilized to control algae and that would prove helpful in the development and use of this wastewater treatment system.

(d) Explain what is meant by *facultative pond.*

1. DOMESTIC WASTEWATER

Domestic wastewater refers to *sanitary wastewater* discharged from residences, commercial buildings, and institutions. Other examples of domestic wastewater sources are mobile homes, hotels, schools, offices, factories, and other commercial enterprises, excluding manufacturing facilities.

The volume of domestic wastewater varies from 50 to 250 gallons per capita day (gpcd) (190 to 950 Lpcd) depending on sewer uses. A more common range for domestic wastewater flow is 100 to 120 gpcd (380 to 450 Lpcd), which assumes that residential dwellings have major water-using appliances such as dishwashers and washing machines.

2. INDUSTRIAL WASTEWATER

Small manufacturing facilities within municipal limits ordinarily discharge *industrial wastewater* into the city sewer system only after pretreatment. In *joint*

processing of wastewater, the municipality accepts responsibility for final treatment and disposal. The manufacturing plant may be required to pretreat the wastewater and equalize flow by holding it in a basin for stabilization prior to discharge to the sewer.

Uncontaminated streams (e.g., cooling water), in many cases, can be discharged into sewers directly. However, pretreatment at the industrial site is required for wastewaters having strengths and/or characteristics significantly different from sanitary wastewater.

To minimize the impact on the sewage treatment plant, consideration is given to modifications in industrial processes, segregation of wastes, flow equalization, and waste strength reduction. Modern industrial/manufacturing processes require segregation of separate waste streams for individual pretreatment, controlled mixing, and/or separate disposal. Process changes, equipment modifications, by-product recovery, and in-plant wastewater reuse can result in cost savings for both water supply and wastewater treatment.

Toxic waste streams are not generally accepted into the municipal treatment plant at all. Toxic substances require appropriate pretreatment prior to disposal by other means.

3. MUNICIPAL WASTEWATER

Municipal wastewater is the general name given to the liquid collected in sanitary sewers and routed to municipal sewage treatment plants. Municipal wastewater includes industrial wastewater and any storm runoff that is collected in storm sewers. Most cities have *combined sewer systems* where storm water and sanitary wastewaters are collected in the same lines. The combined flows are conveyed to the treatment plant for processing during dry weather. During wet weather, when the combined flow exceeds the plant's treatment capacity, the excess flow often bypasses the plant and is discharged directly into the watercourse.

4. WASTEWATER QUANTITY

Approximately 70 to 80% of a community's domestic and industrial water supply returns as wastewater. This water is discharged into the sewer systems, which may or may not also function as storm drains. Therefore, the nature of the return system must be known before sizing can occur.

Sanitary sewer sizing is commonly based on an assumed average of 100 to 125 gpcd (380 to 474 Lpcd). There will be variations in the flow over time, although the variations are not as pronounced as they are for water supply. Hourly variations are the most significant. The flow rate pattern is essentially the same from day to day. Weekend flow patterns are not significantly different from weekday flow patterns. Seasonal variation depends on the location, local industries, and infiltration.

Table 28.1 lists *peaking factors* (i.e., peak multipliers) for treatment plant influent volume. Due to storage in ponds, clarifiers, and sedimentation basins, these multipliers are not applicable throughout all processes in the treatment plant.

Recommended Standards for Sewage Works ("*Ten States' Standards*," abbreviated TSS) specifies that new sanitary sewer systems should be designed for an average flow of 100 gpcd (380 Lpcd or 0.38 m^3/day), which includes an allowance for normal infiltration [TSS Sec. 11.243]. However, the sewer pipe must be sized to carry the peak flow. In the absence of any studies or other justifiable methods, the ratio of peak hourly flow to average flow should be calculated from the following relationship in which P is the ultimate design population in thousands of people.

$$\frac{Q_{\text{peak}}}{Q_{\text{ave}}} = \frac{18 + \sqrt{P}}{4 + \sqrt{P}} \qquad 28.1$$

Infiltration, due to cracks and poor joints in old or broken lines, can increase the sewer flow significantly. Infiltration per mile (kilometer) per in (mm) of pipe diameter is limited by some municipal codes to 500 gpd/mi-in (46 Lpd/km·mm). Modern piping materials and joints easily reduce the infiltration to 200 gpd/in-mi (18 Lpd/km·mm) and below. Infiltration can also be roughly estimated as 3 to 5% of the peak hourly domestic rate or as 10% of the average rate.

Table 28.1 *Typical Variations in Wastewater Flows (based on average daily flow)*

flow description	typical time	location	variation
daily average			100%
daily peak	10 to 12 A.M.	treatment plant	225%
	12 A.M.	outfall	150%
daily minimum	4 to 5 A.M.	treatment plant	40%
seasonal average	May, June		100%
seasonal peak	late summer		125%
seasonal minimum	late winter		90%

Collectors (i.e., *collector sewers, trunks,* or *mains*) are pipes that collect wastewater from individual sources and carry it to interceptors (see Fig. 28.1). Collectors must be designed to handle the maximum hourly flow, including domestic and infiltration, as well as additional discharge from industrial plants nearby. Peak flows of 400 gpcd (1500 Lpcd) for laterals and submains flowing full and 250 gpcd (950 Lpcd) for main, trunk, and outfall sewers are often assumed for design purposes, making the peaking factors approximately 4.0 and 2.5 for submains and mains, respectively. Both of these generalizations include allowances for infiltration.

Interceptors are major sewer lines receiving wastewater from collector sewers and carrying it to a treatment plant or to another interceptor. Interceptors are sized with a peaking factor of 3.5.

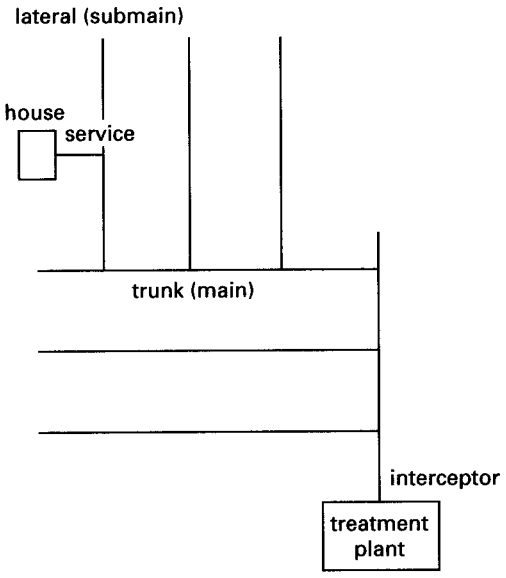

Figure 28.1 *Classification of Sewer Lines*

5. TREATMENT PLANT LOADING

Ideally, the quantity and organic strength of wastewater should be based on actual measurements taken throughout the year in order to account for variations that result from seasonal, climatic changes and other factors.

The *hydraulic loading* for over 75% of the sewage treatment plants in the United States is 1 MGD or less. Plants with flows less than 1 MGD are categorized as *minors*. Treatment plants handling 1 MGD or more, or serving equivalent service populations of 10,000, are categorized as *majors*.

The *organic loading* of treatment units is expressed in terms of pounds (kilograms) of biochemical oxygen demand (BOD) per day or pounds (kilograms) of solids per day. In communities where a substantial portion of the household kitchen wastes is discharged to the sewer system through garbage disposals, the average organic matter contributed by each person each day to domestic wastewater is approximately 0.24 lbm (110 g) of suspended solids and approximately 0.17 to 0.20 lbm (77 to 90 g) of BOD.

Since the average BOD of domestic waste is typically taken as 0.2 pounds per capita day (90 g per capita day), the *population equivalent* of any wastewater source, including industrial sources, can be calculated.

$$P_{\text{equivalent,1000s}} = \frac{(\text{BOD}_{\text{mg/L}})(Q_{\text{ML/day}})}{90\ \frac{\text{g}}{\text{person-day}}} \qquad \text{[SI]} \quad 28.2(a)$$

$$P_{\text{equivalent,1000s}} = \frac{(\text{BOD}_{\text{mg/L}})(Q_{\text{gal/day}}) \times \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right)}{\left(10^6\ \frac{\text{gal}}{\text{MG}}\right)(1000\ \text{persons}) \times (0.20\ \text{lbm/person-day})} \qquad \text{[U.S.]} \quad 28.2(b)$$

6. SEWER PIPE MATERIALS

In the past, sewer pipes were constructed from clay, concrete, asbestos-cement, steel, and cast iron. Due to cost, modern large-diameter sewer lines are now almost always concrete, and new small-diameter lines are generally plastic.

Concrete pipe is commonly used for gravity sewers and pressure mains. Circular pipe is used in most applications, although special shapes (e.g., arch, egg, elliptical) can be used. Concrete pipe in diameters up to 24 in is available in standard 3 and 4 ft (0.9 and 1.2 m) lengths and is usually not reinforced. *Reinforced concrete pipe* (RCP) in diameters ranging from 12 to 144 in (305 to 3660 mm) is available in lengths from 4 to 12 ft (1.2 to 3.6 m).

Concrete pipe is used for large diameter (16 in or larger) trunk and interceptor sewers. In some geographical regions, concrete pipe is used for smaller domestic sewers. However, concrete domestic lines should be selected only where stale or septic sewage is not anticipated. They should not be used with corrosive wastes or in corrosive soils.

Cast-iron pipe is particularly suited to installations where scour, high velocity waste, and high external loads are anticipated. It can be used for domestic connections, although it is more expensive than plastic. Special linings, coatings, wrappings, or encasements are required for corrosive wastes and soils.

Polyvinyl chloride (PVC) and acrylonitrile-butadiene-styrene (ABS) are two *plastic pipe* compositions that can be used for normal domestic sewage and industrial wastewater lines. They have excellent resistance to corrosive soils. However, special attention and care must be given to trench loading and pipe bedding.

ABS plastic can also be combined with concrete reinforcement for collector lines for use with corrosive domestic sewage and industrial waste. Such pipe is known as *truss pipe* due to its construction. The plastic is extruded with inner and outer web-connected pipe walls. The annular voids and the inner and outer walls are filled with lightweight concrete.

For pressure lines, welded steel pipe with an epoxy liner and cement-lined and coated-steel pipe are also used occasionally.

Vitrified clay pipe is resistant to acids, alkalies, hydrogen sulfide (septic sewage), erosion, and scour. Two strengths of clay pipe are available. The standard strength is suitable for pipes less than 12 in (300 mm) in diameter for any depth of cover if the "$4D/3 + 8$ in trench width" ($4D/3 + 200$ mm) rule is observed. Double-strength pipe is recommended for large pipe that is deeply trenched. Clay is seldom used for diameters greater than 36 in (910 mm).

Asbestos-cement pipe has been used in the past for both gravity and pressure sewers carrying non-septic and non-corrosive waste through non-corrosive soils. The lightweight and longer laying lengths are inherent advantages of asbestos-cement pipe. However, such pipes have fallen from favor due to the asbestos content.

7. GRAVITY AND FORCE COLLECTION SYSTEMS

Wastewater collection systems are made up of a network of discharge and flow lines, drains, inlets, valve works, and connections for transporting domestic and industrial wastewater flows to treatment facilities.

Flow through gradually sloping *gravity sewers* is the most desirable means of moving sewage since it does not require pumping energy. In some instances, though, it may be necessary to use pressurized *force mains* to carry sewage uphill or over long, flat distances.

Alternative sewers are used in some remote housing developments for domestic sewage where neither the conventional sanitary sewer nor the septic tank/leach field is acceptable. Alternative sewers use pumps to force raw or communited sewage through small-diameter plastic lines to a more distant communal treatment or collection system.

There are four categories of alternative sewer systems. In the *G-P system*, a grinder-pump pushes chopped-up but untreated wastewater through a small-diameter plastic pipe. The *STEP system* (septic-tank-effluent pumping) uses a septic tank at each house, but there is no leach field. The clear overflow goes to a pump that pushes the effluent through a small-diameter plastic sewer line operating under low pressure. The *vacuum sewer system* uses a vacuum valve at each house that periodically charges a slug of wastewater into a vacuum sewer line. The vacuum is created by a central pumping station. The *small-diameter gravity sewer* (SDG) also uses a small-diameter plastic pipe but relies on gravity instead of pumps. The pipe carries the effluent from a septic tank at each house. Costs in all four systems can be reduced greatly by having two or more houses share septic tanks, pumps, and vacuum valves.

8. SEWER VELOCITIES

The minimum design velocity actually depends on the particulate matter size. However, 2 ft/sec (0.6 m/s) is commonly quoted as the minimum *self-cleansing velocity*, although 1.5 ft/sec (0.45 m/s) may be acceptable if the line is occasionally flushed out by peak flows [TSS Sec. 33.42].

Table 28.2 lists the approximate minimum slope needed to achieve a 2 ft/sec (0.6 m/s) flow. Slopes slightly less than those listed may be permitted (with justification) in lines where design average flow provides a depth of flow greater than 30% of the pipe diameter. Velocity greater than 10 to 15 ft/sec (3 to 4.5 m/s) requires special provisions to protect the pipe and manholes against erosion and displacement by shock hydraulic loadings.

Table 28.2 *Minimum Slopes and Capacities for Sewers*[a]

sewer diameter (in)	sewer diameter (mm)	minimum slope[b] (ft/100 ft or m/100 m)	full flow discharge at minimum slope[c,d] (ft^3/sec)
8	(200)	0.40	0.771
9	(230)	0.33	0.996
10	(250)	0.28	1.17
12	(300)	0.22	1.61
14	(360)	0.17	2.23
15	(380)	0.15	2.52
16	(410)	0.14	2.90
18	(460)	0.12	3.67
21	(530)	0.10	5.05
24	(610)	0.08	6.45
27	(690)	0.067	8.08
30	(760)	0.058	9.96
36	(910)	0.046	14.4

(Multiply in by 25.4 to obtain mm.)
(Multiply ft/100 ft by 1 to obtain m/100 m.)
(Multiply ft^3/sec by 448.8 to obtain gal/min.)
(Multiply ft^3/sec by 28.32 to obtain L/s.)
(Multiply gal/min by 0.0631 to obtain L/s.)
[a] to achieve a velocity of 2 ft/sec (0.6 m/s) when flowing full
[b] as specified in Sec. 24.31 of *Recommended Standards for Sewage Works* (RSSW), also known as "*Ten States' Standards*" (TSS), published by the Health Education Service, Inc. [TSS Sec. 33.41]
[c] $n = 0.013$ assumed
[d] For any diameter in inches, calculate the full flow as

$$Q = (0.0476)(d_{\text{in}})^{\frac{8}{3}}\sqrt{S}$$

9. SEWER SIZING

The Manning equation is traditionally used to size gravity sewers. Depth of flow at the design flow rate is usually less than 70% of the pipe diameter. Thus, a pipe should be sized to be able to carry the peak flow (including normal infiltration) at a depth of approximately 70% of its diameter.

Table 28.3 Minimum Flow Velocities

fluid	minimum velocity to keep particles in suspension ft/sec (m/s)	minimum resuspension velocity ft/sec (m/s)
raw sewage	2.5 (0.75)	3.5 (1.1)
grit tank effluent	2 (0.6)	2.5 (0.75)
primary settling tank effluent	1.5 (0.45)	2 (0.6)
mixed liquor	1.5 (0.45)	2 (0.6)
trickling filter effluent	1.5 (0.45)	2 (0.6)
secondary settling tank effluent	0.5 (0.15)	1 (0.3)

(Multiply ft/sec by 0.3 to obtain m/s.)

In general, sewers in the collection system (including laterals, interceptors, trunks, and mains) should have diameters of at least 8 in (203 mm). Building service connections can be as small as 4 in (101 mm).

10. STREET INLETS

Street inlets are required at all low points where ponding could occur, and they should be placed no more than 600 ft (180 m) apart, and a limit of 300 ft (90 m) is preferred. A common practice is to install three inlets in a sag vertical curve—one at the lowest point and one on each side with an elevation of 0.2 ft (60 mm) above the center inlet.

Depth of gutter flow is found using Manning's equation. Inlet capacities of street inlets have traditionally been calculated from semi-empirical formulas.

Grate-type street inlets (known as *gutter inlets*) less than 0.4 ft (120 mm) deep have approximate capacities given by Eq. 28.3. Equation 28.3 should also be used for combined curb-grate inlets. All dimensions are in ft. For gutter inlets, the bars should ideally be parallel to the flow and at least 1.5 ft (450 mm) long. Gutter inlets are more efficient than curb inlets, but clogging is a problem. Depressing the grating level below the street level increases the capacity.

$$Q_{\text{ft}^3/\text{sec}} = 3.0(\text{grate perimeter length}) \times (\text{inlet flow depth})^{\frac{3}{2}} \quad 28.3$$

The capacity of a *curb inlet* (where there is an opening in the vertical plane of the gutter rather than in the horizontal plane) is given by Eq. 28.4. All dimensions are in ft. Not all curb inlets have inlet depressions. A typical curb inlet depression is 0.4 ft (130 mm).

$$Q_{\text{ft}^3/\text{sec}} = 0.7(\text{curb opening length}) \times (\text{inlet flow depth} + \text{curb inlet depression})^{\frac{3}{2}} \quad 28.4$$

11. MANHOLES

Manholes along sewer lines should be provided at sewer line intersections and at changes in elevation, direction, size, diameter, and slope. If a sewer line is too small for a person to enter, manholes should be placed every 400 ft (120 m) to allow for cleaning. Recommended maximum spacings are 400 ft (120 m) for pipes with diameters less than 18 in (460 mm), 500 ft (150 m) for 18 to 48 in (460 to 1220 mm) pipes, and 600 to 700 ft (180 to 210 m) for larger pipes.

12. SULFIDE ATTACK

Wastewater flowing through sewers often turns septic and releases *hydrogen sulfide* gas, H_2S. The common *Thiobacillus* sulfur bacterium converts the hydrogen sulfide to sulfuric acid. The acid attacks the crown of concrete pipes.

$$2H_2S + O_2 \rightarrow 2S + 2H_2O \quad 28.5$$

$$2S + 3O_2 + 2H_2O \rightarrow 2H_2SO_4 \quad 28.6$$

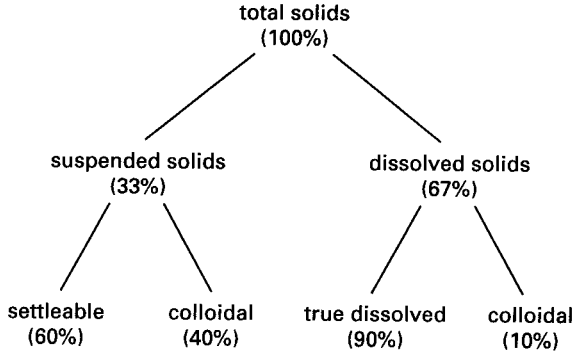
In warm climates, hydrogen sulfide can be generated in sanitary sewers placed along on flat grades. Hydrogen sulfide also occurs in sewers supporting food processing industries. Sulfide generation is aggravated by the use of home garbage disposals and, to a lesser extent, by recycling. Interest in nutrition and fresh foods has also added to food wastes.

Sulfide attack can be prevented by maintaining the flow rate above 5 ft/sec (1.5 m/s), raising the pH above 10.4, using biocides, precipitating the sulfides, or a combination thereof. Not all methods may be possible or economical, however. In sewers, the least expensive method generally involves intermittent (e.g., biweekly during the critical months) *shock treatments* of sodium hydroxide and ferrous chloride. The sodium hydroxide is a sterilization treatment that works by raising the pH, while the ferrous chloride precipitates the sulfides.

13. WASTEWATER CHARACTERISTICS

Not all sewage flows are the same. Some sewages are stronger than others. Table 28.4 lists typical values for strong and weak domestic sewages.

14. SOLIDS



Solids in wastewater are categorized in the same manner as in water supplies. *Total solids* consist of *suspended* and *dissolved solids*. Generally, total solids constitute only a small amount of the incoming flow—less than 1/10% by mass. Therefore, wastewater fluid properties are essentially those of water. Figure 28.2 illustrates the solids categorization, along with typical percentages. Each category can be further divided into organic and inorganic groups.

Environmental

Table 28.4 *Strong and Weak Domestic Sewages*[a]

constituent	strong	weak
solids, total	1200	350
dissolved, total	850	250
fixed	525	145

organic	35	8
free ammonia	50	12
nitrites	0	0
nitrates	0	0
phosphorus (total as P)	20	6
organic	5	2
inorganic	15	4
chlorides	100	30
alkalinity (as $CaCO_3$)	200	50
grease	150	50

[a] All concentrations are in mg/L unless noted.

[a] typical percentages given

Figure 28.2 *Wastewater Solids*[a]

The amount of *volatile solids* can be used as a measure of the organic pollutants capable of affecting the oxygen content. As in water supply testing, volatile solids are measured by igniting filtered solids and measuring the decrease in mass.

Refractory solids (*refractory organics*) are solids that are difficult to remove by common wastewater treatment processes.

15. MICROBIAL GROWTH

For the large numbers and mixed cultures of microorganisms found in waste treatment systems, it is more convenient to measure biomass than numbers of organisms. This is accomplished by measuring suspended or volatile suspended solids. An expression that depicts the rate of conversion of food into biomass for wastewater treatment was developed by Monod.

Equation 28.7 calculates the rate of growth, r_g, of a bacterial culture as a function of the rate of concentration of limiting food in solution. The growth rate, X, of microorganisms, with dimensions of mass per unit volume (e.g., mg/L) is given by Eq. 28.7. μ is a specific growth rate factor with dimensions of time^{-1}.

$$r_g = \frac{dX}{dt} = \mu X \qquad 28.7$$

When one essential nutrient (referred to as a *substrate*) is present in a limited amount, the specific growth rate will increase up to a maximum value and is given by *Monod's equation*, Eq. 28.8. μ_m is the maximum specific growth rate with dimensions of time^{-1}. S is the concentration of the growth-limiting nutrient with dimensions of mass/unit volume. K_s is the *half-velocity coefficient*, the nutrient concentration at one half of the maximum growth rate, with dimensions of mass/unit volume.

$$\mu = \mu_m \left(\frac{S}{K_s + S} \right) \qquad 28.8$$

Combining Eqs. 28.7 and 28.8, the rate of growth is

$$r_g = \frac{\mu_m X S}{K_s + S} \qquad 28.9$$

The rate of substrate (nutrient) utilization is easily calculated if the *maximum yield coefficient*, Y, defined as the ratio of the mass of cells formed to the mass of nutrient consumed (with dimensions of mass/mass) is known.

$$r_{su} = \frac{dS}{dt} = \frac{-\mu_m X S}{Y(K_s + S)} \qquad 28.10$$

The maximum rate of substrate utilization per unit mass of microorganisms is

$$k = \frac{\mu_m}{Y} \qquad 28.11$$

Combining Eqs. 28.10 and 28.11,

$$dS/dt = \frac{-kXS}{K_s + S} \qquad 28.12$$

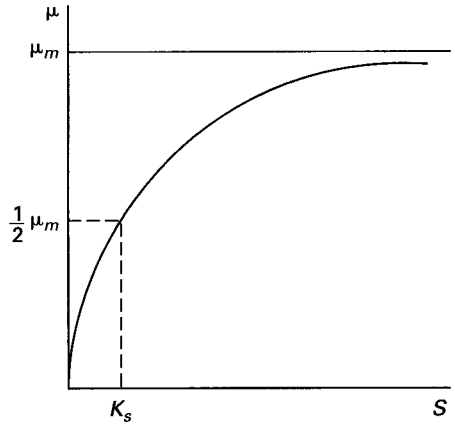

Figure 28.3 *Bacterial Growth Rate with Limited Nutrient*

The Monod equation assumes that all microorganisms are the same age. The actual distribution of ages and other factors (death and predation of cells) decreases the rate of cell growth. The decrease is referred to as *endogenous decay* and is accounted for with an *endogenous decay coefficient*, k_d, with dimensions of time^{-1}. The rate of endogenous decay is

$$r_d = -k_d X \qquad 28.13$$

The net rate of cell growth and net specific growth rate are

$$r'_g = \frac{\mu_m X S}{K_s + S} - k_d X = -Y r_{su} - k_d X \qquad 28.14$$

$$\mu' = \mu_m \left(\frac{S}{K_s + S} \right) - k_d \qquad 28.15$$

16. DISSOLVED OXYGEN IN WASTEWATER

A body of water exposed to the atmosphere will normally become saturated with oxygen. If the dissolved oxygen content, DO, of water is less than the saturated values (given in App. 22.D), there will be good reason to believe that the water is organically polluted.

The difference between the saturated and actual dissolved oxygen concentration is known as the *oxygen deficit*, D.

$$D = \mathrm{DO_{sat}} - \mathrm{DO} \qquad 28.16$$

17. REOXYGENATION

The oxygen deficit can be reduced (i.e., the dissolved oxygen concentration can be increased) only by aerating the water. This occurs naturally in free-running water (e.g., in rivers). The rate of reaeration is

$$r_r = K_r(\mathrm{DO_{sat}} - \mathrm{DO}) \qquad 28.17$$

An exponential model is used to predict the oxygen deficit, D, as a function of time during a pure reoxygenation process.

$$D_t = D_0 10^{-K_r t} \qquad 28.18$$

K_r is the *reoxygenation (reaeration) rate constant*, which depends on the type of flow and temperature and with common units of days^{-1}. (K_r may be written as K_R and K_2 by some authorities.) Typical values of K_r are: small stagnant ponds, 0.05 to 0.10; sluggish streams, 0.10 to 0.15; large lakes, 0.10 to 0.15; large streams, 0.15 to 0.30; swiftly flowing rivers and streams, 0.3 to 0.5; whitewater and waterfalls, 0.5 and above.

K_r can be approximated from the *O'Connor and Dobbins formula* for natural streams if field test data are not available.

$$K_{r,20^\circ\mathrm{C}} \approx \frac{1.69\sqrt{\mathrm{v_{m/s}}}}{d_{\mathrm{m}}^{\frac{3}{2}}} \qquad 28.19$$

Another empirical formula that has been proposed is

$$K_{r,20^\circ\mathrm{C}} \approx \frac{3.3\mathrm{v_{ft/sec}}}{d_{\mathrm{ft}}^{1.33}} \qquad 28.20$$

The variation in K_r with temperature is given approximately by Eq. 28.21. The constant 1.024 has been reported as 1.016 by some authorities. K_r is considered to be independent of temperature.

$$K_{r,T} = K_{r,20^\circ\mathrm{C}}(1.024)^{T-20^\circ\mathrm{C}} \qquad 28.21$$

Equation 28.21 is actually a special case of Eq. 28.22, which gives the relationship between values of K_r between any two temperatures.

$$K_{r,T_1} = K_{r,T_2}\theta_r^{T_1 - T_2} \qquad 28.22$$

Although base-10 values of K_r are more common, reoxygenation constants are also given for use with a natural logarithmic base. In that case, Eq. 28.18 would be written as Eq. 28.23. (The constant K'_r may be written as $K_{r,\text{base-}e}$ by some authorities.)

$$D_t = D_0 e^{-K'_r t} \qquad 28.23$$

The constants K_r and K'_r are different but related.

$$K'_r = 2.303 K_r \qquad 28.24$$

18. DEOXYGENATION

The rate of deoxygenation at time t is

$$r_{d,t} = -K_d \mathrm{BOD}_u \qquad 28.25$$

The *deoxygenation rate constant*, K_d, for treatment plant effluent is approximately 0.05 to 0.10 day^{-1} and is typically taken as 0.1 day^{-1} (base-10 values). (K_d may be represented as K and K_1 by some authorities.) For highly polluted shallow streams, it can be as high as 0.25 day^{-1}. For raw sewage, it is approximately 0.15 to 0.30 day^{-1}.

K_d for other temperatures can be found from Eq. 28.26. The *temperature variation constant*, θ, is often quoted in literature as 1.047. However, this value should not be used with temperatures below 68°F (20°C). Additional research suggests the K_d values from 1.135 for temperatures between 39°F to 68°F (4°C to 20°C), and up to 1.056 for temperatures between 68°F to 86°F (20°C to 30°C).

$$K_{d,T} = K_{d,20°C}\theta^{T-20°C} \qquad 28.26$$

Equation 28.26 is actually a special case of Eq. 28.27, which gives the relationship between values of K_d between any two temperatures.

$$K_{d,T_1} = K_{d,T_2}\theta_d^{T_1-T_2} \qquad 28.27$$

19. TESTS OF WASTEWATER CHARACTERISTICS

The most common wastewater analyses used to determine characteristics of a municipal wastewater determine biochemical oxygen demand (BOD) and suspended solids (SS). BOD and flow data are basic requirements for the operation of biological treatment units. The concentration of suspended solids relative to BOD indicates the degree that organic matter is removable by primary settling. Additionally, temperature, pH, COD, alkalinity, color, grease, and the quantity of heavy metals are necessary to specify municipal wastewater characteristics.

20. BIOCHEMICAL OXYGEN DEMAND

When oxidizing organic material in water, biological organisms also remove oxygen from the water. This is typically considered to occur through oxidation of organic material to CO_2 and H_2O by microorganisms at the molecular level and is referred to as *biochemical oxygen demand* (BOD). Therefore, oxygen use is an indication of the organic waste content.

Typical values of BOD for various industrial wastewaters are given in Table 28.5. A BOD of 100 mg/L is considered to be a weak wastewater; a BOD of 200 to 250 mg/L is considered to be a medium strength wastewater; and a BOD above 300 mg/L is considered to be a strong wastewater.

Table 28.5 *Typical BOD and COD of Industrial Wastewaters*

industry/ type of waste	BOD	COD
canning		
corn	19.5 lbm/ton corn	
tomatoes	8.4 lbm/ton tomatoes	
dairy milk		
processing	1150 lbm/ton raw milk 1000 mg/L	1900 mg/L
beer brewing	1.2 lbm/barrel beer	
commercial		
laundry	1250 lbm/1000 lbm dry 700 mg/L	2400 mg/L
slaughterhouse (meat packing)	7.7 lbm/animal 1400 mg/L	2100 mg/L
papermill	121 lbm/ton pulp	
synthetic textile	1500 mg/L	3300 mg/L
chlorophenolic manufacturing	4300 mg/L	5400 mg/L
milk bottling	230 mg/L	420 mg/L
cheese production	3200 mg/L	5600 mg/L
candy production	1600 mg/L	3000 mg/L

In the past, the BOD has been determined in a lab using a traditional standardized BOD testing procedure. Since this procedure requires five days of incubating, online measurement systems have been developed to provide essentially instantaneous and continuous BOD information at wastewater plants.

The standardized BOD test consists of adding a measured amount of wastewater (which supplies the organic material) to a measured amount of dilution water (which reduces toxicity and supplies dissolved oxygen) and then incubating the mixture at a specific temperature. The standard procedure calls for a five-day incubation period at 68°F (20°C), though other temperatures are used. The measured BOD is designated as BOD_5 or BOD-5. The BOD of a biologically active sample at the end of the incubation period is given by Eq. 28.28.

$$\mathrm{BOD_5} = \frac{\mathrm{DO}_i - \mathrm{DO}_f}{\dfrac{\mathrm{V_{sample}}}{\mathrm{V_{sample}} + \mathrm{V_{dilution}}}} \qquad 28.28$$

If more than one identical sample is prepared, the increase in BOD over time can be determined, rather than just the final BOD. Figure 28.4 illustrates a typical plot of BOD versus time. The BOD at any time t is known as the *BOD exertion*.

BOD exertion can be found from Eq. 28.29. The ultimate BOD (BOD_u) is the total oxygen used by *carbonaceous bacteria* if the test is run for a long period of time, usually taken as 20 days. (The symbols L, BOD_L, and BOD_{ult} are also widely used to represent the ultimate BOD.)

$$\mathrm{BOD}_t = \mathrm{BOD}_u(1 - 10^{-K_d t}) \qquad 28.29$$

The ultimate BOD, BOD_u, usually cannot be found from long-term studies due to the effect of nitrogen-consuming bacteria in the sample. However, if K_d is 0.1 day^{-1}, the ultimate BOD can be found from Eq. 28.30.

$$BOD_u \approx 1.47BOD_5 \qquad 28.30$$

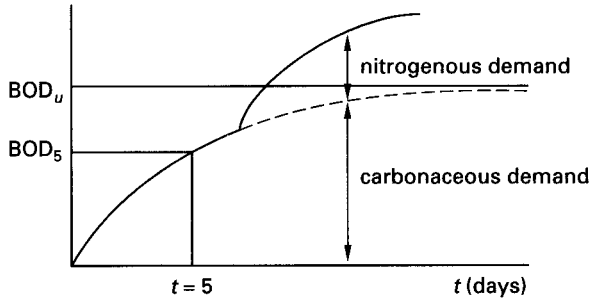

Figure 28.4 *BOD Exertion*

The approximate variation in BOD (either BOD_5 or BOD_u) with temperature is given by Eq. 28.31.

$$BOD_{T°C} = BOD_{20°C}(0.02T_{°C} + 0.6) \qquad 28.31$$

The deviation from the expected exponential growth curve in Fig. 28.4 is due to nitrification and is considered to be *nitrogenous demand*. *Nitrification* is the use of oxygen by autotrophic bacteria. Autotrophic bacteria oxidize ammonia to nitrites and nitrates.

The number of autotrophic bacteria in a wastewater sample is initially small. Generally, 6 to 10 days are required for the autotrophic population to become sufficiently large to affect a BOD test. Therefore, the standard BOD test is terminated at five days, before the autotrophic contribution to BOD becomes significant.

Until recently, BOD has not played a significant role in the daily operations decisions of treatment plants because of the length of time it took to obtain BOD data. Other measurements, such as COD, TOC, turbidity, suspended solids, respiration rates, or flow have been used.

Example 28.1

Ten 5 mL samples of wastewater are placed in 300 mL BOD bottles. Half of the bottles are titrated immediately, and the average initial concentration of dissolved oxygen is found to be 7.9 mg/L. The remaining bottles are incubated for five days, after which the average dissolved oxygen is determined to be 4.5 mg/L. The deoxygenation rate constant is known to be 0.13 day^{-1}. What are the (a) standard BOD and (b) ultimate carbonaceous BOD?

Solution

(a) Use Eq. 28.28.

$$BOD_5 = \frac{DO_i - DO_f}{\frac{V_{sample}}{V_{sample} + V_{dilution}}}$$

$$= \frac{7.9\ \frac{mg}{L} - 4.5\ \frac{mg}{L}}{\frac{5\ mL}{300\ mL}}$$

$$= 204\ mg/L$$

(b) From Eq. 28.29, the ultimate BOD is

$$BOD_u = \frac{BOD_t}{1 - 10^{-K_d t}}$$

$$= \frac{204\ \frac{mg}{L}}{1 - 10^{(-0.13\ day^{-1})(5\ days)}}$$

$$= 263\ mg/L$$

21. SEEDED BOD

Industrial wastewater may lack sufficient microorganisms to metabolize the organic matter. In this situation, the standard BOD test will not accurately determine the amount of organic matter unless seed organisms are added.

The BOD in seeded samples is found by measuring dissolved oxygen in the seeded sample after 15 min (DO_i) and after five days (DO_f), as well as by measuring the dissolved oxygen of the seed material itself after 15 min (DO_i^*) and after five days (DO_f^*). In Eq. 28.32, x is the ratio of the volume of seed added to the sample to the volume of seed used to find DO*.

$$BOD = \frac{DO_i - DO_f - x(DO_i^* - DO_f^*)}{\frac{V_{sample}}{V_{sample} + V_{dilution}}} \qquad 28.32$$

22. DILUTION PURIFICATION

Dilution purification (also known as *self-purification*) refers to the discharge of untreated or partially treated sewage into a large body of water such as a river. After the treatment plant effluent has mixed with the river water, the river experiences both deoxygenation (from the biological activity of the waste) and reaeration (from the agitation of the flow). If the body is large and is adequately oxygenated, the sewage's BOD may be satisfied without putrefaction.

When two streams merge, the characteristics of the streams are blended in the combined flow. If values of the characteristics of interest are known for the upstream flows, the blended concentration can be found

Environmental

as a weighted average. Equation 28.33 can be used to calculate the final temperature, dissolved oxygen, BOD, or suspended solids content immediately after two flows are mixed. (The subscript a is also used in the literature to represent the condition immediately after mixing.)

$$C_f = \frac{C_1Q_1 + C_2Q_2}{Q_1 + Q_2} \qquad 28.33$$

Example 28.2

6 MGD of wastewater with a dissolved oxygen concentration of 0.9 mg/L is discharged into a 50°F river flowing at 40 ft^3/sec. The river is initially saturated with oxygen. What is the oxygen content of the river immediately after mixing?

Solution

Both flow rates must have the same units. Convert MGD to ft^3/sec.

$$Q_w = \frac{(6\text{ MGD})\left(10^6\ \frac{\text{gal}}{\text{MG}}\right)}{\left(7.48\ \frac{\text{gal}}{\text{ft}^3}\right)\left(24\ \frac{\text{hr}}{\text{day}}\right)\left(60\ \frac{\text{min}}{\text{hr}}\right)\left(60\ \frac{\text{sec}}{\text{min}}\right)}$$
$$= 9.28\ \text{ft}^3/\text{sec}$$

From App. 22.D, the saturated oxygen content at 50°F (10°C) is 11.3 mg/L. From Eq. 28.33,

$$C_f = \frac{C_wQ_w + C_rQ_r}{Q_w + Q_r}$$
$$= \frac{\left(0.9\ \frac{\text{mg}}{\text{L}}\right)\left(9.28\ \frac{\text{ft}^3}{\text{sec}}\right) + \left(11.3\ \frac{\text{mg}}{\text{L}}\right)\left(40\ \frac{\text{ft}^3}{\text{sec}}\right)}{9.28\ \frac{\text{ft}^3}{\text{sec}} + 40\ \frac{\text{ft}^3}{\text{sec}}}$$
$$= 9.34\ \text{mg/L}$$

23. RESPONSE TO DILUTION PURIFICATION

The oxygen deficit is the difference between actual and saturated oxygen concentrations, expressed in mg/L. Since reoxygenation and deoxygenation of a polluted river occur simultaneously, the oxygen deficit will increase if the reoxygenation rate is less than the deoxygenation rate. If the oxygen content goes to zero, anaerobic decomposition and putrefaction will occur.

The minimum dissolved oxygen concentration that will protect aquatic life in the river is the *dissolved oxygen standard* for the river. 4 to 6 mg/L is the generally accepted range of dissolved oxygen required to support fish populations. 5 mg/L is adequate as is evidenced in high-altitude trout lakes. However, 6 mg/L is preferable, particularly for large fish populations.

The oxygen deficit at time t is given by the *Streeter-Phelps equation.* In Eq. 28.34, BOD_u is the ultimate carbonaceous BOD of the river immediately after mixing. D_0 is the dissolved oxygen deficit immediately after mixing, which is often given the symbol D_a. (If the constants K_r and K_d are base-e constants, the base-10 exponentiation in Eq. 28.36 should be replaced with the base-e exponentiation, e^x.)

$$D_t = \left(\frac{K_d\text{BOD}_u}{K_r - K_d}\right)(10^{-K_dt} - 10^{-K_rt}) + D_0(10^{-K_rt}) \qquad 28.34$$

A graph of dissolved oxygen versus time (or distance downstream) is known as a dissolved oxygen *sag curve.* The location at which the lowest dissolved oxygen concentration occurs is the *critical point.* The location of the critical point is found from the river velocity and flow time to that point.

$$x_c = \text{v}t_c \qquad 28.35$$

The time to the critical point is given by Eq. 28.36. The ratio K_r/K_d in Eq. 28.36 is known as the *self-purification constant.* (If the constants K_r and K_d are base-e constants, the base-10 logarithm in Eq. 28.36 should be replaced with the base-e logarithm, ln.)

$$t_c = \left(\frac{1}{K_r - K_d}\right) \times \log_{10}\left[\left(\frac{K_d\text{BOD}_u - K_rD_0 + K_dD_0}{K_d\text{BOD}_u}\right)\left(\frac{K_r}{K_d}\right)\right] \qquad 28.36$$

The critical oxygen deficit is given by Eq. 28.37.

$$D_c = \left(\frac{K_d\text{BOD}_u}{K_r}\right)10^{-K_dt_c} \qquad 28.37$$

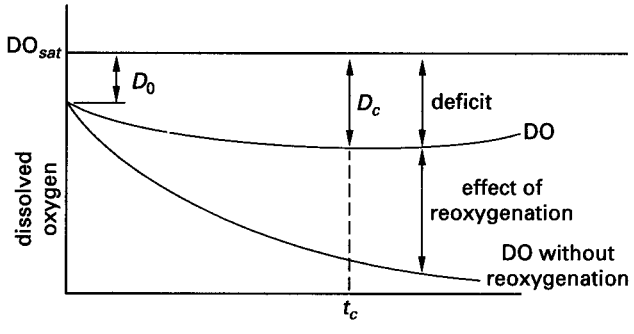

Figure 28.5 *Oxygen Sag Curve*

Example 28.3

A treatment plant effluent has the following characteristics.

quantity	15 ft^3/sec
$BOD_{5,20°C}$	45 mg/L BOD
DO	2.9 mg/L
temperature	24°C
$K_{d,20°C}$	0.1 day^{-1}
temperature variation constant for K_d, θ_d	1.047
temperature variation constant for K_r, θ_r	1.016

The outfall is located in a river carrying 120 ft^3/sec of water with the following characteristics.

quantity	120 ft^3/sec
velocity	0.55 ft/sec
average depth	4 ft
$BOD_{5,20°C}$	4 mg/L
DO	8.3 mg/L
temperature	16°C

When the treatment plant effluent and river are mixed, the mixture temperature persists for a long distance downstream.

(a) Determine the distance downstream where the oxygen level is at a minimum. (b) Determine if the river can support fish life at that point.

Solution

(a) Find the river conditions immediately after mixing. Use Eq. 28.33 three times.

$$C_f = \frac{C_1Q_1 + C_2Q_2}{Q_1 + Q_2}$$

$$\text{BOD}_{20°C} = \frac{\left(15\ \frac{\text{ft}^3}{\text{sec}}\right)\left(45\ \frac{\text{mg}}{\text{L}}\right) + \left(120\ \frac{\text{ft}^3}{\text{sec}}\right)\left(4\ \frac{\text{mg}}{\text{L}}\right)}{15\ \frac{\text{ft}^3}{\text{sec}} + 120\ \frac{\text{ft}^3}{\text{sec}}}$$

$$= 8.56\ \text{mg/L}$$

$$\text{DO} = \frac{\left(15\ \frac{\text{ft}^3}{\text{sec}}\right)\left(2.9\ \frac{\text{mg}}{\text{L}}\right) + \left(120\ \frac{\text{ft}^3}{\text{sec}}\right)\left(8.3\ \frac{\text{mg}}{\text{L}}\right)}{15\ \frac{\text{ft}^3}{\text{sec}} + 120\ \frac{\text{ft}^3}{\text{sec}}}$$

$$= 7.7\ \text{mg/L}$$

$$T = \frac{\left(15\ \frac{\text{ft}^3}{\text{sec}}\right)(24°C) + \left(120\ \frac{\text{ft}^3}{\text{sec}}\right)(16°C)}{15\ \frac{\text{ft}^3}{\text{sec}} + 120\ \frac{\text{ft}^3}{\text{sec}}}$$

$$= 16.89°C$$

Calculate the rate constants. From Eq. 28.26,

$$K_{d,T} = K_{d,20°C}(1.047)^{T-20°C}$$

$$K_{d,16.89°C} = (0.1\ day^{-1})(1.047)^{16.89°C-20°C}$$

$$= 0.0867\ day^{-1}$$

From Eq. 28.20,

$$K_{r,20°C} \approx \frac{3.3v}{d^{1.33}}$$

$$= \frac{(3.3)\left(0.55\ \frac{\text{ft}}{\text{sec}}\right)}{(4\ \text{ft})^{1.33}}$$

$$= 0.287\ day^{-1}$$

From Eq. 28.21,

$$K_{r,T} = K_{r,20°C}(1.016)^{T-20°C}$$

$$K_{r,16.89°C} = (0.287\ day^{-1})(1.016)^{16.89°C-20°C}$$

$$= 0.273\ day^{-1}$$

Estimate BOD_u from Eq. 28.29.

$$\text{BOD}_{u,20°C} = \frac{\text{BOD}_5}{1 - 10^{-K_d t}}$$

$$= \frac{8.56\ \frac{\text{mg}}{\text{L}}}{1 - 10^{(-0.1\ day^{-1})(5\ day)}}$$

$$= 12.52\ \text{mg/L}$$

From Eq. 28.31,

$$\text{BOD}_T = \text{BOD}_{20°C}(0.02T_{°C} + 0.6)$$

$$\text{BOD}_{u,16.89°C} = \left(12.52\ \frac{\text{mg}}{\text{L}}\right)\left((0.02)(16.89°C) + 0.6\right)$$

$$= 11.74\ \text{mg/L}$$

Calculate the original oxygen deficit. From App. 22.D, the dissolved oxygen concentration at 16.89°C is approximately 9.7 mg/L.

$$D_0 = 9.7\ \frac{\text{mg}}{\text{L}} - 7.7\ \frac{\text{mg}}{\text{L}} = 2\ \text{mg/L}$$

Environmental

Calculate t_c from Eq. 28.36.

$$t_c = \left(\frac{1}{K_r - K_d}\right) \times \log_{10}\left[\left(\frac{K_d\text{BOD}_u - K_r D_0 + K_d D_0}{K_d\text{BOD}_u}\right)\left(\frac{K_r}{K_d}\right)\right]$$

$$= \left(\frac{1}{0.273\ \text{day}^{-1} - 0.0867\ \text{day}^{-1}}\right) \times \log_{10}\left[\left(\frac{(0.0867\ \text{day}^{-1})\left(11.74\ \frac{\text{mg}}{\text{L}}\right) - (0.273\ \text{day}^{-1})\left(2\ \frac{\text{mg}}{\text{L}}\right) + (0.0867\ \text{day}^{-1})\left(2\ \frac{\text{mg}}{\text{L}}\right)}{(0.0867\ \text{day}^{-1})\left(11.74\ \frac{\text{mg}}{\text{L}}\right)}\right) \times \left(\frac{0.273\ \text{day}^{-1}}{0.0867\ \text{day}^{-1}}\right)\right]$$

$$= 1.61 \text{ days}$$

The distance downstream is

$$x_c = \text{v}t_c = \frac{\left(0.55\ \frac{\text{ft}}{\text{sec}}\right)(1.61 \text{ days})\left(86{,}400\ \frac{\text{sec}}{\text{day}}\right)}{5280\ \frac{\text{ft}}{\text{mi}}} = 14.5 \text{ mi}$$

The critical oxygen deficit is found from Eq. 28.37.

$$D_c = \left(\frac{K_d\text{BOD}_u}{K_r}\right) 10^{-K_d t_c} = \left(\frac{(0.0867\ \text{day}^{-1})\left(11.74\ \frac{\text{mg}}{\text{L}}\right)}{0.273\ \text{day}^{-1}}\right) \times \left(10^{(-0.0867\ \text{day}^{-1})(1.61\ \text{day})}\right) = 2.7 \text{ mg/L}$$

(b) If the temperature 15.9 mi downstream is 16°C, the standard oxygen content is 10 mg/L. Since the critical deficit is 3 mg/L, the minimum oxygen content is 7 mg/L. This is adequate for fish life.

24. CHEMICAL OXYGEN DEMAND

Chemical oxygen demand (COD) is a measure of a maximum oxidizable substance (unlike biochemical oxygen demand, which is a measure of oxygen removed only by biological organisms). Therefore, COD is a good measure of total effluent strength.

COD testing is required where there is industrial chemical pollution. In such environments, the organisms necessary to metabolize organic compounds may not exist. Furthermore, the toxicity of the wastewater may make the standard BOD test impossible to carry out. Standard COD test results are usually available in a matter of hours.

If toxicity is low, BOD and COD test results can be correlated. The BOD/COD ratio typically varies from 0.4 to 0.8. This is a wide range but, for any given treatment plant and waste type, the correlation is essentially constant. The correlation can, however, vary along the treatment path.

25. RELATIVE STABILITY

The *relative stability* test is easier to perform than the BOD test, although it is less accurate. The relative stability of an effluent is defined as the percentage of initial BOD that has been satisfied. The test consists of taking a sample of effluent and adding a small amount of methylene blue dye. The mixture is then incubated, usually at 20°C. When all oxygen has been removed from the water, anaerobic bacteria start to remove the dye. The amount of time it takes for the color to start degrading is known as the *stabilization time* or *decoloration time*. The relative stability can be found from the stabilization time by using Table 28.6.

Table 28.6 *Relative Stability*[a]

stabilization time (days)	relative stability[b] (%)
1/2	11

26. CHLORINE DEMAND

Chlorination destroys bacteria, hydrogen sulfide, and other compounds and substances. The *chlorine demand* (*chlorine dose*) must be determined by careful monitoring of coliform counts and free residuals since there are several ways that chlorine can be used up without producing significant disinfection. Only after uncombined (free) chlorine starts showing up is it assumed that all chemical reactions and disinfection are complete.

Chlorine demand is the amount of chlorine (or its chloramine or hypochlorite equivalent) required to leave the desired residual (usually 0.5 mg/L) 15 min after mixing. Fifteen minutes is the recommended mixing and holding time prior to discharge, since during this time nearly all pathogenic bacteria in the water will have been killed.

Typical doses for wastewater effluent depend on the application point and are widely variable, though doses rarely exceed 30 mg/L. For example, chlorine may be applied at 5 to 25 mg/L prior to primary sedimentation, 2 to 6 mg/L after sand filtration, and 3 to 15 mg/L after trickle filtration.

27. BREAKPOINT CHLORINATION

Because of their reactivities, chlorine is initially used up in the neutralization of hydrogen sulfide and the rare ferrous and manganous (Fe^{+2} and Mn^{+2}) ions. For example, hydrogen sulfide is oxidized according to Eq. 28.38. The resulting HCl, $FeCl_2$, and $MnCl_2$ ions do not contribute to disinfection. They are known as *unavailable combined residuals.*

$$H_2S + 4H_2O + 4Cl_2 \rightarrow H_2SO_4 + 8HCl \qquad 28.38$$

Ammonia nitrogen combines with chlorine to form the family of *chloramines.* Depending on the water pH, monochloramines (NH_2Cl), dichloramines ($NHCl_2$), or trichloramines (nitrogen trichloride, NCl_3) may form. Chloramines have long-term disinfection capabilities and are therefore known as *available combined residuals.* Equation 28.39 is a typical chloramine formation reaction.

$$NH_4^+ + HOCl \leftrightarrow NH_2Cl + H_2O + H^+ \qquad 28.39$$

The continued addition of chlorine after chloramines begin forming changes the pH and allows chloramine destruction to begin. Chloramines are converted to nitrogen gas (N_2) and nitrous oxide (N_2O). Equation 28.40 is a typical chloramine destruction reaction.

$$2NH_2Cl + HOCl \leftrightarrow N_2 + 3HCl + H_2O \qquad 28.40$$

The destruction of chloramines continues, with the repeated application of chlorine, until no ammonia remains in the water. The point at which all ammonia has been removed is known as the *breakpoint.*

In the *breakpoint chlorination* method, additional chlorine is added after the breakpoint in order to obtain free chlorine residuals. The free residuals have a high disinfection capacity. Typical free residuals are free chlorine (Cl_2), hypochlorous acid (HOCl), and hypochlorite ions. Equations 28.41 and 28.42 illustrate the formation of these free residuals.

$$Cl_2 + H_2O \rightarrow HCl + HOCl \qquad 28.41$$

$$HOCl \rightarrow H^+ + ClO^- \qquad 28.42$$

There are several undesirable characteristics of breakpoint chlorination. First, it may not be economical to use breakpoint chlorination unless the ammonia nitrogen has been reduced. Second, free chlorine residuals produce trihalomethanes. Third, if free residuals are prohibited to prevent trihalomethanes, the water may need to be dechlorinated using sulfur dioxide gas or sodium bisulfate. (Where small concentrations of free residuals are permitted, dechlorination may be needed only during the dry months. During winter storm months, the chlorine residuals may be adequately diluted with rain water.)

28. NITROGEN

Nitrogen occurs in water in organic, ammonia, nitrate, nitrite, and dissolved gaseous forms. Nitrogen in municipal wastewater results from human excreta, ground garbage, and industrial wastes (primarily food processing). Bacterial decomposition and the hydrolysis of urea produces ammonia, NH_3. Ammonia in water forms the ammonium ion NH_4^+, also known as *ammonia nitrogen.* Ammonia nitrogen must be removed from the waste effluent stream due to potential exertion of oxygen demand.

Nitrification (the oxidation of ammonia nitrogen) occurs as follows.

$$NH_4^+ + 2O_2 \rightarrow NO_3^- + H_2O + 2H^+ \qquad 28.43$$

$$2NO_3^- + \text{organic matter} \rightarrow N_2 + CO_2 + H_2O \qquad 28.44$$

Ammonia nitrogen can be removed (*denitrification*) chemically from water by raising the pH level. This converts the ammonium ion back into ammonia, which can then be stripped from the water by passing large quantities of air through the water. Lime is added to provide the hydroxide for the reaction. The *ammonia stripping* reaction is

$$NH_4^+ + OH^- \rightarrow NH_3 + H_2O \qquad 28.45$$

Ammonia stripping has no effect on nitrate, which is commonly removed in an activated sludge process with a short cell detention time.

29. ORGANIC COMPOUNDS IN WASTEWATER

Biodegradable organic matter in municipal wastewater is classified into three major categories: proteins, carbohydrates, and greases (fats).

Proteins are long strings of amino acids containing carbon, hydrogen, oxygen, nitrogen, and phosphorus.

Carbohydrates consist of sugar units containing the elements of carbon, hydrogen, and oxygen. They are identified by the presence of a saccharide ring. The rings range from simple monosaccharides to polysaccharides (long chain sugars categorized as either readily degradable starches found in potatoes, rice, corn, and other edible plants, or as cellulose found in wood and similar plant tissues).

Greases are a variety of biochemical substances that have the common property of being soluble to varying degrees in organic solvents (acetone, ether, ethanol, and hexane) while being only sparingly soluble in water. The low solubility of grease in water causes problems in pipes and tanks where it accumulates, reduces contact areas during various filtering processes, and produces a sludge that is difficult to dispose of.

Degradation of greases by microorganisms occurs at a very slow rate. A simple fat is a triglyceride composed of a glycerol unit with short-chain or long-chain fatty acids attached.

The majority of carbohydrates, fats, and proteins in wastewater are in the form of large molecules that cannot penetrate the cell membrane of microorganisms. Bacteria, in order to metabolize high molecular-weight substances, must be capable of breaking down the large molecules into diffusible fractions for assimilation into the cell. Of the organic matter in wastewater, 60 to 80% is readily available for biodegradation.

Several organic compounds such as cellulose, long-chain saturated hydrocarbons, and other complex compounds, although available as a bacterial substrate, are considered nonbiodegradable because of the time and environmental limitations of biological wastewater treatment systems.

Volatile organic chemicals (VOCs) are released in large quantities in industrial, commercial, agricultural, and household activities. The adverse health effects of VOCs include cancer and chronic effects on the liver, kidney, and nervous system. *Synthetic organic chemicals* (SOCs) and *inorganic chemicals* (IOCs) are used in agricultural and industrial processes as pesticides, insecticides, and herbicides.

Organic petroleum derivatives, detergents, pesticides, and other synthetic, organic compounds are particularly resistant to biodegradation in wastewater treatment plants, and some are toxic and inhibit the activity of microorganisms in biological treatment processes.

30. HEAVY METALS IN WASTEWATER

Metals are classified by four categories: *Dissolved metals* are those constituents of an unacidified sample that pass through a 0.45 μm membrane filter. *Suspended metals* are those constituents of an unacidified sample retained by a 0.45 μm membrane filter. *Total metals* are the concentration determined on an unfiltered sample after vigorous digestion or the sum of both dissolved and suspended fractions. *Acid-extractable metals* remain in solution after treatment of an unfiltered sample with hot dilute mineral acid.

The metal concentration in the wastewater is calculated from Eq. 28.46. The sample size is selected so that the product of the sample size (in mL) and the metal concentration (C, in mg/L) is approximately 1000.

$$C = \frac{C_{\text{digestate}} V_{\text{digested solution}}}{V_{\text{sample}}} \qquad 28.46$$

Some metals are biologically essential; others are toxic and adversely affect wastewater treatment systems and receiving waters.

31. WASTEWATER COMPOSITING

Proper sampling techniques are essential for accurate evaluation of wastewater flows. Samples should be well mixed, representative of the wastewater flow stream in composition, taken at regular time intervals, and stored properly until analysis can be performed. *Compositing* is the sampling procedure that accomplishes these goals.

Samples are collected (i.e., "grabbed," hence the name *grab sample*) at regular time intervals (e.g., every hour on the hour), stored in a refrigerator or ice chest, and then integrated to formulate the desired combination for a particular test. Flow rates are measured at each sampling to determine the wastewater flow pattern.

The total volume of the composite sample desired depends on the kinds and number of laboratory tests to be performed.

32. WASTEWATER STANDARDS

Treatment plants and industrial complexes must meet all applicable wastewater quality standards for surface waters, drinking waters, air, and effluents of various types. For example, standards for discharges from secondary treatment plants are given in terms of *maximum contaminant levels* (MCLs) for five-day BOD, suspended solids, coliform count, and pH. Some chemicals, compounds, and microbial varieties are regulated; others are unregulated but monitored. MCLs for regulated and monitored chemicals, compounds, and microbes are subject to ongoing legislation and change.

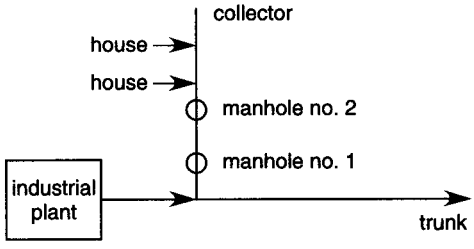
PRACTICE PROBLEMS

Sewer Velocities and Sizing

1. (*Time limit: one hour*) A town of 10,000 people has its own primary treatment plant.

(a) What mass of total solids should the treatment plant expect?

(A) 57 lbm/day
(B) 740 lbm/day
(C) 3800 lbm/day
(D) 8300 lbm/day



The answer is (D).

(b) If the town is 4 mi from the treatment plant and 400 ft above it in elevation, what size pipe should be used between the town and the plant, assuming that the pipe flows full?

(A) 8 in
(B) 12 in
(C) 14 in
(D) 18 in

The answer is (C).

2. (*Time limit: one hour*) Your client has just completed a subdivision, and his sewage lines hook up to a collector that goes into a trunk. A problem has developed in the first manhole up from the trunk, and the collector pipe overflows periodically. An industrial plant is hooked directly into the trunk, and it is this plant's flow that is making your client's line back up. The subdivision is in a flood plain, and the sewer lines are very flat and cannot be steepened. (a) Describe two possible solutions to this problem. (b) Sketch plan views of your solutions.

Dilution

3. Town A wants to discharge wastewater into a river upstream of town B. The state standard level for dissolved oxygen is 5 mg/L. Other data pertinent to this problem are given in the following table.

parameter	town A	river
flow (m^3/s)	0.280	0.877
ultimate BOD at 28°C (mg/L)	6.44	7.00
DO (mg/L)	1.00	6.00
K_d at 28°C, day^{-1} (base-10)	N/A	0.199
K_r at 28°C, day^{-1} (base-10)	N/A	0.370
velocity (m/s)	N/A	0.650
temperature (°C)	28	28

(a) Will the dissolved oxygen level of town B be reduced below the state standard level?

(A) yes; DO = 4.1 mg/L
(B) yes; DO = 4.8 mg/L
(C) no; DO = 5.3 mg/L
(D) no; DO = 5.9 mg/L

The answer is (B).

(b) At a distance of 5.79 km downstream, will the dissolved oxygen level be below the state standard level?

(A) yes; DO = 4.1 mg/L
(B) yes; DO = 4.8 mg/L
(C) no; DO = 5.3 mg/L
(D) no; DO = 5.9 mg/L

The answer is (B).

(c) At any point downstream, will the dissolved oxygen level be below the state standard level?

(A) yes; DO = 4.1 mg/L
(B) yes; DO = 4.7 mg/L
(C) no; DO = 5.1 mg/L
(D) no; DO = 5.5 mg/L

The answer is (B).

(d) Determine if the discharge will reduce the dissolved oxygen in the river below the state standard level if the winter river temperature drops to 12°C and all other characteristics remain the same.

(A) yes; DO = 4.5 mg/L
(B) yes; DO = 4.9 mg/L
(C) no; DO = 5.1 mg/L
(D) no; DO = 5.8 mg/L

The answer is (C).

4. To protect aquatic life, the limit on increase in temperature in a certain stream is 2°C at seasonal low flow. In addition, the stream must not contain more than 0.002 mg/L of un-ionized ammonia.

A manufacturing facility proposes to draw cooling water from the stream and return it to the stream at a higher temperature. They will also be discharging some un-ionized ammonia in the cooling water.

The critical low flow in the stream is 1200 m^3/s at a temperature of 20°C. The stream has no measurable un-ionized ammonia in its natural state. The facility intends to withdraw 60 m^3/s of cooling water and return it to the stream without loss of mass.

(a) What is the maximum temperature for the discharge water if the stream is not to be damaged?

(A) 40°C
(B) 60°C
(C) 80°C
(D) 90°C

The answer is (B).

(b) What is the maximum ammonia concentration for the discharge water if the stream is not to be damaged?

(A) 0.04 mg/L
(B) 0.06 mg/L
(C) 0.09 mg/L
(D) 0.13 mg/L

The answer is (A).

5. A rural town of 10,000 people discharges partially treated wastewater into a stream. The stream has the following characteristics.

minimum flow rate	120 ft^3/sec
velocity	3 mi/hr
minimum dissolved oxygen	7.5 mg/L at 15°C
temperature	15°F
BOD	0

The reoxygenation and deoxygenation coefficients are

reoxygenation coefficient of stream and effluent mixture:	0.2 day^{-1} at 20°C
deoxygenation coefficient:	0.1 day^{-1} at 20°C

The town's effluent has the following characteristics.

source	volume	BOD at 20°C	temp.
domestic	122 gpcd	0.191 lbm/cd	64°F
infiltration	116,000 gpd		
industrial no. 1	180,000 gpd	800 mg/L	95°F
industrial no. 2	76,000 gpd	1700 mg/L	84°F

(a) What is the domestic waste BOD in mg/L at 20°C?

(A) 140 mg/L
(B) 160 mg/L
(C) 190 mg/L
(D) 220 mg/L

The answer is (C).

(b) What is the average effluent BOD in mg/L at 20°C just before discharge into the stream?

(A) 245 mg/L
(B) 270 mg/L
(C) 295 mg/L
(D) 315 mg/L

The answer is (D).

(c) What is the average temperature of the effluent just before discharge into the stream?

(A) 20°C
(B) 30°C
(C) 50°C
(D) 70°C

The answer is (A).

(d) If the wastewater does not contribute to dissolved oxygen at all, how far downstream is the theoretical point of minimum dissolved oxygen concentration?

(A) 30 mi
(B) 70 mi
(C) 80 mi
(D) 120 mi

The answer is (B).

(e) What is the theoretical minimum dissolved oxygen concentration in the stream?

(A) 4.7 mg/L
(B) 5.5 mg/L
(C) 7.2 mg/L
(D) 8.3 mg/L

The answer is (C).

6. A sewage treatment plant is being designed to handle both domestic and industrial wastewaters. The city population is 20,000, and a population expansion factor of 15% is to be used for future domestic expansion. The wastewaters have the following characteristics.

source	volume	BOD
domestic	100 gpcd	0.18 lbm/cd
industrial no. 1	1.3 MGD	1100 mg/L
industrial no. 2	1.0 MGD	500 mg/L

(a) What is the design population equivalent for the plant?

(A) 65,000
(B) 92,000
(C) 100,000
(D) 110,000

The answer is (D).

(b) What is the plant's organic loading?

(A) 2300 lbm/day
(B) 8100 lbm/day
(C) 14,000 lbm/day
(D) 20,000 lbm/day

The answer is (D).

(c) What is the plant's hydraulic loading?

(A) 4.6 MGD
(B) 5.8 MGD
(C) 6.3 MGD
(D) 7.5 MGD

The answer is (A).

1. INDUSTRIAL WASTEWATER TREATMENT

The *National Pollution Discharge Elimination System* (NPDES) places strict controls on the discharge of industrial wastewaters into municipal sewers. Any industrial wastes that would harm subsequent municipal

treatment facilities or that would upset subsequent biological processes need to be pretreated. Manufacturing plants may also be required to equalize wastewaters by holding them in basins for stabilization prior to their discharge to the sewer. Table 29.1 lists typical limitations on industrial wastewaters.

Table 29.1 *Typical Industrial Wastewater Effluent Limitations*

characteristic	concentration[a], mg/L
COD	300–2000
BOD	100–300
oil and grease or TPH[b]	15–55
total suspended solids	15–45
pH	6.0–9.0
temperature	less than 40°C
color	2 color units
NH_3/NO_3	1.0–10
phosphates	0.2
heavy metals	0.1–5.0
surfactants	0.5–1.0 (total)
sulfides	0.01–0.1
phenol	0.1–1.0
toxic organics	1.0 total
cyanide	0.1

[a]maximum permitted at discharge
[b]total petroleum hydrocarbons

2. CESSPOOLS

A *cesspool* is a previously dug covered pit into which domestic (i.e., household) sewage is discharged. Cesspools for temporary storage can be constructed as watertight enclosures. However, most are *leaching cesspools* that allow seepage of liquid into the soil. Cesspools are rarely used today. They are acceptable for disposal for only very small volumes (e.g., from a few families).

3. SEPTIC TANKS

A *septic tank* is a simply constructed tank that holds domestic sewage while sedimentation and digestion occur. Typical detention times are 8 to 24 hr. Only 30 to 50% of the suspended solids are digested in a septic tank. The remaining solids settle, clogging the tank, and eventually must be removed. Semi-clarified effluent percolates into the surrounding soil through lateral lines placed at the *flow line* and that lead into an underground leach field. In the past, clay drainage tiles were used. The terms "tile field" and "tile bed" are still encountered even though perforated plastic pipe is now widely used.

Most septic tanks are built for use by one to three families. Larger communal tanks can be constructed for small groups (they should be designed to hold 12 to 24 hours of flow plus stored sludge). A general rule is to allow at least 30 gal (0.1 m^3) of storage per person served by the tank. Typical design parameters of domestic septic tanks are contained in Table 29.2.

Proper design of the percolation field is the key to successful operation. Soils studies are essential to ensure adequate absorption into the soil.

Table 29.2 *Typical Characteristics of Domestic Septic Tanks*

minimum capacity below flow line	300–500 gal (1.1–1.9 m^3), plus 30 gal (0.1 m^3) for each person served over 5
plan aspect ratio	1:2
minimum depth below flow line	3–4 ft (0.9–1.2 m)
minimum freeboard above flow line	1 ft (0.3 m)
tank burial depth	1–2 ft (0.3–0.6 m)
drainage field tile length	30 ft (9 m) per person
maximum drainage field tile length	60 ft (18 m)
minimum tile depth	1.5–2.5 ft (0.45–0.75 m)
lateral line spacing	6 ft (1.8 m)
gravel bed	0.33 ft (1 m) above lateral, 1 ft (0.3 m) below
soil layer below tile bed	10 ft (3 m)

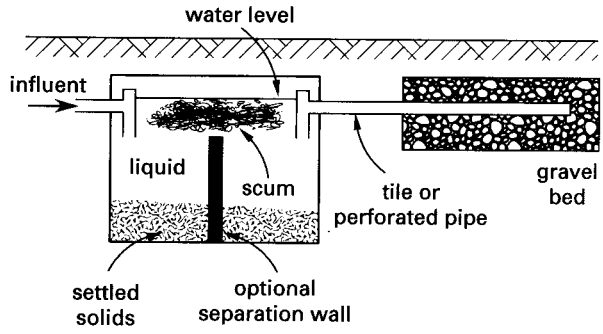

Figure 29.1 *Septic Tank*

4. DISPOSAL OF SEPTAGE

Septage is the water and solid material pumped periodically from septic tanks, cesspools, or privies. In the United States, disposal of septage is controlled by federal sludge disposal regulations, and most local and state governments have their own regulations, as well. While surface and land spreading were acceptable disposal methods in the past, septage haulers are now turning to municipal treatment plants for disposal. Since septage is many times more concentrated than sewage, it can cause *shock loads* in preliminary treatment processes. Typical problems are: plugged screens and aerator inlets, reduced efficiency in grit chambers and aeration basins, and increased odors. The impact on subsequent processes is less pronounced due to the effect of dilution.

Table 29.3 *Comparison of Typical Septage and Municipal Sewage*[a]

characteristic	septage	sewage[b]
BOD	7000	220
COD	15,000	500
total solids	40,000	720
total volatile solids	25,000	365
total suspended solids	15,000	220
volatile suspended solids	10,000	165
TKN	700	40
NH_3 as N	150	25
alkalinity	1000	100
grease	8000	100
pH	6.0	–

[a] all values except pH in mg/L
[b] medium strength

5. WASTEWATER TREATMENT PLANTS

For traditional *wastewater treatment plants* (WWTP), *preliminary treatment* of the wastewater stream is essentially a mechanical process intended to remove large objects, rags, and wood. Heavy solids and excessive oils and grease are also eliminated. Damage to pumps and other equipment would occur without preliminary treatment.

Odor control through chlorination or ozonation, freshening of septic waste by aeration, and flow equalization in holding basins can also be loosely categorized as pretreatment processes.

After preliminary treatment, there are four "levels" of wastewater treatment: primary, secondary, tertiary, and quaternary. *Primary treatment* is a mechanical (settling) process used to remove oil and most (i.e., approximately 50%) of the settleable solids. With domestic wastewater, a 25 to 35% reduction in BOD is also achieved, but BOD reduction is not the goal of primary treatment.

In the United States, secondary treatment is mandatory for all publicly owned water treatment plants. *Secondary treatment* involves biological treatment in trickling filters, rotating contactors, biological beds, and activated sludge processes (covered in Chap. 30). Processing typically reduces the suspended solids and BOD content by more than 85%, volatile solids by 50%, total nitrogen by about 25%, and phosphorus by 20%.

Tertiary treatment and *quaternary treatment* (also known as *advanced wastewater treatment*, AWT) are targeted at specific pollutants or wastewater characteristics that have passed through previous processes in concentrations that are not allowed in the discharge. *Suspended solids* are removed by microstrainers or polishing filter beds. *Phosphorus* is removed by chemical precipitation. Aluminum and iron coagulants, as well as lime, are effective in removing phosphates. *Ammonia* can be removed by air stripping, biological denitrification, breakpoint chlorination, anion exchange, and algae ponds. Ions from *inorganic salts* can be removed by electrodialysis and reverse osmosis. The so-called *trace organics* or *refractory substances, dissolved organic solids* that are resistant to biological processes, can be removed by filtering through carbon or ozonation.

6. WASTEWATER PLANT SITING CONSIDERATIONS

Wastewater plants should be located as far as possible from inhabited areas. A minimum distance of 1000 ft (300 m) for uncovered plants and lagoons is desired. Uncovered plants should be located downwind when a definite wind direction prevails. Soil conditions need to be evaluated, as does the proximity of the water table. Elevation in relationship to the need for sewage pumping (and for dikes around the site) is relevant.

The plant must be protected against flooding. One hundred-year storms are often chosen as the design flood when designing dikes and similar facilities. Distance to the outfall and possible effluent pumping need to be considered.

Table 29.4 lists the approximate acreage for sizing wastewater treatment plants. Estimates of population expansion should provide for future capacity.

Table 29.4 *Treatment Plant Acreage Requirements*

type of treatment	surface area required (ac/MGD)
physical-chemical plants	1.5
activated sludge plants	2
trickling filter plants	3
aerated lagoons	16
stabilization basins	20

7. PUMPS USED IN WASTEWATER PLANTS

Wastewater treatment plants should be gravity-fed wherever possible. The influent of most plants is pumped to the starting elevation, and wastewater flows through subsequent processes by gravity thereafter. However, there are still many instances when pumping is required. Table 29.5 lists pump types by application.

At least two identical pumps should be present at every location, each capable of handling the entire peak flow. Three or more pumps are required for flows greater than 1 MGD, and peak flow should be handled when one of the pumps is being serviced.

8. FLOW EQUALIZATION

Equalization tanks or ponds are used to smooth out variations in flow that would otherwise overload wastewater processes. Graphical or tabular techniques similar to those used in reservoir sizing can be used to size equalization ponds. In practice, up to 25% excess capacity is added as a safety factor.

Table 29.5 *Pumps Used in Wastewater Plants*

flow	flow rate gal/min (L/min)	pump type
raw sewage	<50 (190)	pneumatic ejector
	50–200 (190–760)	submersible or end-suction, nonclog centrifugal
	>200 (760)	end-suction, nonclog centrifugal
settled sewage	<500 (1900)	end-suction, nonclog centrifugal
	>500 (1900)	vertical axial or mixed-flow centrifugal
sludge, primary, thickened, or digested		plunger
sludge, secondary		end-suction, nonclog centrifugal
scum		plunger or recessed impeller
grit		recessed impeller, centrifugal, pneumatic ejector, or conveyor rake

In a pure flow equalization process, there is no settling. Mechanical aerators provide the turbulence necessary to keep the solids in suspension while providing oxygen to prevent putrefaction. For typical municipal wastewater, air is provided at the rate of 1.25 to 2.0 ft^3/min-1000 gal (0.01 to 0.015 $m^3/min \cdot m^3$). Power requirements are approximately 0.02 to 0.04 hp/1000 gal (4 to 8 W/m^3).

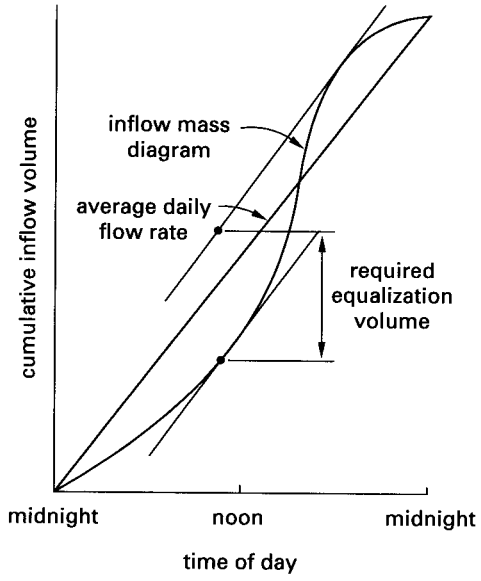

Figure 29.2 *Equalization Volume: Mass Diagram Method*

9. STABILIZATION PONDS

The term *stabilization pond* (*oxidation pond* or *stabilization lagoon*) refers to a pond used to treat organic waste by biological and physical processes. Aquatic plants, weeds, algae, and microorganisms stabilize the organic matter. The algae give off oxygen that is used by microorganisms to digest the organic matter. The microorganisms give off carbon dioxide, ammonia, and phosphates that the algae use. Even in modern times, such ponds may be necessary in remote areas (e.g., national parks and campgrounds). To keep toxic substances from leaching into the ground, ponds should not be used without strictly enforced industrial pretreatment requirements.

There are several types of stabilization ponds. *Aerobic ponds* are shallow ponds, less than 4 ft (1.2 m) in depth, where dissolved oxygen is maintained throughout the entire depth, mainly by action of photosynthesis. *Facultative ponds* have an anaerobic lower zone, a facultative middle zone, and an aerobic upper zone. The upper zone is maintained in an aerobic condition by photosynthesis and, in some cases, mechanical aeration at the surface. *Anaerobic ponds* are so deep and receive such a high organic loading that anaerobic conditions prevail throughout the entire pond depth. *Maturation ponds* (*tertiary ponds* or *polishing ponds*) are used for polishing effluent from secondary biological processes. Dissolved oxygen is furnished through photosynthesis and mechanical aeration. *Aerated lagoons* are oxygenated through the action of surface or diffused air aeration. They are often used with activated sludge processes.

Table 29.6 *Typical Characteristics of Nonaerated Stabilization Ponds*

minimum depth	2 ft (0.6 m)
maximum depth	6 ft (1.8 m)
BOD loading[a,b]	15–35 lbm/ac-day (17–45 kg/ha·day)
detention time[c]	
controlled-discharge pond	180 days minimum
flow-through stabilization pond	90–120 days typical
number of cells	3 minimum
maximum cell size	40 ac (16 ha)
minimum dike width	8 ft (2.4 m)
maximum dike wall slope	1:3 (vertical:horizontal)
minimum dike wall slope	1:4 (vertical:horizontal)
minimum freeboard	3 ft (1 m)

[a] at mean depth
[b] Facultative ponds are seldom loaded at greater than 20 lbm/ac-day (22 kg BOD/ha·day).
[c] between depths of 2 ft (0.6 m) and the maximum

10. FACULTATIVE PONDS

Facultative ponds are the most common pond type selected for small communities. Approximately 25% of the municipal wastewater treatment plants in this country use ponds, and about 90% of these are located in communities of 5000 people or fewer. Long retention times and volumes easily handle large fluctuations in wastewater flow and strength with no significant effect on effluent quality. Also capital, operating, and maintenance costs are less than for other biological systems that provide equivalent treatment.

In a facultative pond, raw wastewater enters at the center of the pond. Suspended solids contained in the wastewater settle to the pond bottom where an anaerobic layer develops. A facultative zone develops just above the anaerobic zone. Molecular oxygen is not available in the region at all times. Generally, the zone is aerobic during the daylight hours and anaerobic during the hours of darkness.

An aerobic zone with molecular oxygen present at all times exists above the facultative zone. Some oxygen is supplied from diffusion across the pond surface, but the majority is supplied through algal photosynthesis.

General guidelines are used to design facultative ponds. Ponds may be round, square, or rectangular. Usually, there are three cells, piped to permit operation in series or in parallel. Two of the three cells should be identical, each capable of handling half of the peak design flow. The third cell should have a minimum volume of one-third of the peak design flow.

11. AERATED LAGOONS

An *aerated lagoon* is a stabilization pond that is mechanically aerated. Such lagoons are typically deeper and have shorter detention times than nonaerated ponds. In warm climates and with floating aerators, one acre can support several hundred pounds (a hundred kilograms) of BOD per day.

The basis for the design of aerated lagoons is typically the organic loading and/or detention time. The detention time will depend on the desired BOD reduction fraction, η, and the reaction constant, k. Other factors that must be considered in the design process are solids removal requirements, oxygen requirements, temperature effects, and energy for mixing.

The BOD reduction can be calculated from the overall, first-order BOD *removal rate constant*, k_1. Typical values of $k_{1,\text{base-10}}$ (as specified by TSS) are 0.12 day^{-1} at 20°C and 0.06 day^{-1} at 1°C.

$$t_d = \frac{V}{Q} = k_{1,\text{base-}e}^{1-\eta} \qquad 29.1$$

$$k_{1,\text{base-}e} = 2.3k_{1,\text{base-10}} \qquad 29.2$$

Aeration should maintain a minimum oxygen content of 2 mg/L at all times. Design depth is larger than for nonaerated lagoons—10 to 15 ft (3 to 4.5 m). Common design characteristics of mechanically aerated lagoons are shown in Table 29.7. Other characteristics are similar to those listed in Table 29.6.

Table 29.7 *Typical Characteristics of Aerated Lagoons*

aspect ratio	less than 3:1
depth	10–15 ft (3.0–4.5 m)
detention time	4–10 days
BOD loading	20–400 lbm/day-ac; 200 lbm/day-ac typical (22–440 kg/day·ha; 220 kg/day·ha typical)
operating temperature	0–38°C (21°C optimum)
typical effluent BOD	20–70 mg/L
oxygen required	0.7–1.4 times BOD removed

12. RACKS AND SCREENS

Trash racks or *coarse screens* with openings 2 in or larger should precede pumps to prevent clogging. *Medium screens* ($\frac{1}{2}$ in to $1\frac{1}{2}$ in openings) and *fine screens* ($\frac{1}{16}$ in to $\frac{1}{8}$ in) are also used to relieve the load on grit chambers and sedimentation basins. Fine screens are rare except when used with selected industrial waste processing plants. Screens in all but the smallest municipal plants are cleaned by automatic scraping arms. A minimum of two screen units is advisable.

Screen capacities and head losses are specified by the manufacturer. Although the flow velocity must be sufficient to maintain sediment in suspension, the approach velocity should be limited to 3 ft/sec (0.9 m/s) to prevent debris from being forced through the screen.

13. GRIT CHAMBERS

Abrasive *grit* can erode pumps, clog pipes, and accumulate in excessive volumes. In a *grit chamber* (also known as *grit clarifier* or *detritus tank*) the wastewater is slowed, allowing the grit to settle out but allowing the organic matter to continue through. Grit can be manually or mechanically removed with buckets or screw conveyors. A minimum of two units is needed.

Horizontal flow grit chambers are designed to keep the flow velocity as close to 1 ft/sec (0.3 m/s) as possible. If an analytical design based on settling velocity is required, the *scouring velocity* should not be exceeded. Scouring is the dislodging of particles that have already settled. Scouring velocity is not the same as settling velocity.

Scouring will be prevented if the horizontal velocity is kept below that predicted by the *Camp formula*, Eq. 29.3. SG_p is the specific gravity of the particle, typically taken as 2.65 for sand. d_p is the particle diameter. k is a dimensionless constant with typical values of 0.04

for sand and 0.06 or more for sticky, interlocking matter. The dimensionless Darcy friction factor is approximately 0.02 to 0.03. Any consistent set of units can be used with Eq. 29.3.

$$v = \sqrt{8k\left(\frac{gd_p}{f}\right)(SG_p - 1)} \qquad 29.3$$

Table 29.8 *Typical Characteristics of Grit Chambers*

grit size	0.2 mm and larger
grit specific gravity	2.65
grit arrival/removal rate	0.5–5 ft^3/MG ($4–40\times10^{-6}$ m^3/m^3)
depth of chamber	4–10 ft (1.2–3 m)
length	40–100 ft (12–30 m)
width	varies (not critical)
detention time	90–180 sec
horizontal velocity	0.75–1.25 ft/sec (0.23–0.38 m/s)

14. AERATED GRIT CHAMBERS

An *aerated grit chamber* is a bottom-hoppered tank with a short detention time. Diffused aeration from one side of the tank rolls the water and keeps the organics in suspension while the grit drops into the hopper. The water spirals or rolls through the tank. Influent enters through the side and removes the degritted wastewater. A minimum of two units is needed.

Solids are removed by pump, screw conveyer, bucket elevator, or gravity flow. However, the grit will have a significant organic content. A grit washer or cyclone separator can be used to clean the grit.

Table 29.9 *Typical Characteristics of Aerated Grit Chambers*

detention time	2–5 min at peak flow; 3 min typical
air supply	
shallow tanks	1.5–5 cfm/ft length; 3 typical (0.13–0.45 m^3/min·m; 0.27 typical)
deep tanks	3–8 cfm/ft length; 5 typical (0.27–0.7 m^3/min·m; 0.45 typical)
grit and scum quantity	0.5–25 ft^3/MG (2 typical) ($4–190\times10^{-6}$ m^3/m^3)
length:width ratio	2:5:1–5:1 (3:1 typical)
depth	6–15 ft (1.8–4.5 m)
length	20–60 ft (6–18 m)
width	7–20 ft (2.1–6 m)

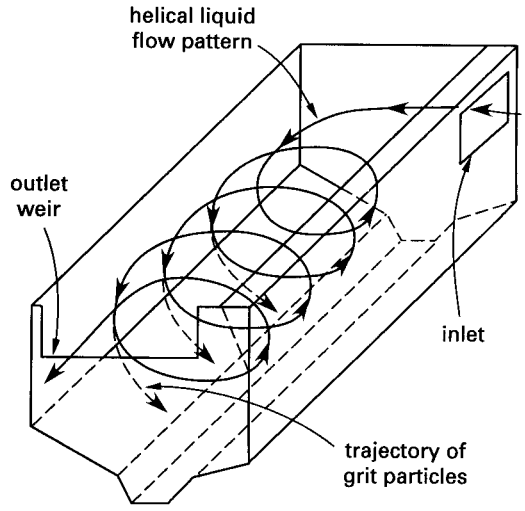

Figure 29.3 *Aerated Grit Chamber*

15. SKIMMING TANKS

If the sewage has more than 50 mg/L of floating grease or oil, a basin 8 to 10 ft (2.4 to 3 m) providing 5 to 15 min of detention time will allow the grease to rise as *floatables* (*scum*) to the surface. An aerating device will help coagulate and float grease to the surface. 40 to 80 psig (280 to 550 kPa) of air should be provided at the approximate rate of 0.01 to 0.1 ft^3/gal (0.07 to 0.7 m^3/m^3) of influent. A small fraction (e.g., 30%) of the influent may be recycled in some cases. Grease rise rates are typically 0.2 to 1 ft/min (0.06 to 0.5 m/min) depending on the degree of dispersal, amount of colloidal fines, and aeration.

Scum is mechanically removed by skimming troughs. Scum may not generally be disposed of by landfilling. It is processed with other solid wastes in anaerobic digesters. *Scum grinding* may be needed to reduce the scum to a small enough size for thorough digestion. In some cases, scum may be incinerated, although this practice may be affected by air-quality regulations.

16. SHREDDERS

Shredders (also called *comminutors*) cut waste solids to approximately 1/4 in (6 mm) in size, reducing the amount of screenings that must be disposed of. Shreddings stay with the flow for later settling.

17. PLAIN SEDIMENTATION BASINS/CLARIFIERS

Plain sedimentation basins/clarifiers (i.e., basins in which no chemicals are added to encourage clarification) are similar in concept and design to those used to treat water supplies. Design characteristics for wastewater treatment sedimentation basins are listed in

Table 29.10. The *surface loading* (*surface loading rate, overflow rate,* or *settling rate*), v^*, along with sludge storage volume, is the primary design parameter.

$$v^* = \frac{Q}{A} \qquad 29.4$$

The *detention time* (*mean residence time* or *retention period*) is

$$t_d = \frac{V}{Q} \qquad 29.5$$

The *weir loading* (*weir loading rate*) is

$$\text{weir loading} = \frac{Q}{L} \qquad 29.6$$

Table 29.10 *Typical Characteristics of Plain Sedimentation Basins*

BOD reduction	20–40% (25–35% typical)
total suspended solids reduction	35–65%
bacteria reduction	50–60%
organic content of settled solids	50–75%
specific gravity of settled solids	1.2 or less
minimum settling velocity	4 ft/hr (1.2 m/hr) typical
plan shape	rectangular (or circular)
basin depth	6–15 ft; 12 ft typical (1.8–4.5 m; 3.6 m typical)
basin width	10–50 ft (3–15 m)
plan aspect ratio	3:1 to 5:1
basin diameter (circular only)	50–150 ft; 100 ft typical (15–45 m; 30 m typical)
minimum freeboard	1.5 ft (0.45 m)
minimum hopper wall angle	60°
detention time	1.5–2.5 hr
flow-through velocity	18 ft/hr (1.5 mm/s)
minimum flow-through time	30% of detention time
weir loading	10,000–20,000 gal/day-ft (125–250 m^3/day·m)
surface loading	400–2000 gal/day-ft^2; 800–1200 gal/day-ft^2 typical (16–80 m^3/day·m^2; 32–50 m^3/day·m^2 typical)
bottom slope to hopper	8%
inlet	baffled to prevent turbulence
scum removal	mechanical or manual

18. CHEMICAL SEDIMENTATION BASINS/CLARIFIERS

Chemical flocculation (*clarification* or *coagulation*) operations in chemical sedimentation basins are similar to those encountered in the treatment of water supplies except that the coagulant doses are greater. Chemical precipitation may be used when plain sedimentation is insufficient, or occasionally when the stream into which the outfall discharges is running low, or when there is a large increase in sewage flow. As with water treatment, the five coagulants used most often are (a) aluminum sulfate, $Al_2(SO_4)_3$; (b) ferric chloride, $FeCl_3$; (c) ferric sulfate, $Fe_2(SO_4)_3$; (d) ferrous sulfate, $FeSO_4$; and (e) chlorinated copperas. Lime and sulfuric acid may be used to adjust the pH for proper coagulation.

Example 29.1

A primary clarifier receives 1.4 MGD of domestic waste. The clarifier has a peripheral weir, is 50 ft in diameter, and is filled to a depth of 7 ft. Determine if the clarifier has been sized properly.

Solution

The perimeter length is

$$L = \pi D = \pi(50 \text{ ft}) = 157 \text{ ft}$$

The surface area is

$$A = \frac{\pi}{4}D^2 = \left(\frac{\pi}{4}\right)(50 \text{ ft})^2 = 1963 \text{ ft}^2$$

The volume is

$$V = AZ = (1963 \text{ ft}^2)(7 \text{ ft}) = 13{,}740 \text{ ft}^3$$

The surface loading should be 400 to 2000 gal/day-ft^2.

$$v^* = \frac{Q}{A} = \frac{1.4 \times 10^6 \ \frac{\text{gal}}{\text{day}}}{1963 \text{ ft}^2}$$
$$= 713 \text{ gal/day-ft}^2 \quad \text{[OK]}$$

The detention time should be 1.5 to 2.5 hr.

$$t = \frac{V}{Q} = \frac{(13{,}740 \text{ ft}^3)\left(24 \ \frac{\text{hr}}{\text{day}}\right)}{\left(1.4 \times 10^6 \ \frac{\text{gal}}{\text{day}}\right)\left(0.1337 \ \frac{\text{ft}^3}{\text{gal}}\right)}$$
$$= 1.76 \text{ hr} \quad \text{[OK]}$$

The weir loading should be 10,000 to 20,000 gal/day-ft.

$$\frac{Q}{L} = \frac{1.4 \times 10^6 \ \frac{\text{gal}}{\text{day}}}{157 \text{ ft}}$$
$$= 8917 \text{ gal/day-ft} \quad \text{[low but probably OK]}$$

19. TRICKLING FILTERS

Trickling filters (also known as *biological beds* and *fixed media filters*) consist of beds of rounded river rocks with approximate diameters of 2 to 5 in (50 to 125 mm), wooden slats, or modern synthetic media. Wastewater from primary sedimentation processing is sprayed intermittently over the bed. The biological and microbial slime growth attached to the bed purifies the wastewater as it trickles down. The water is introduced into the filter by rotating arms that move by virtue of spray reaction (reaction-type) or motors (motor-type). The clarified water is collected by an underdrain system.

The distribution rate is sometimes given by an *SK rating*, where SK is the water depth in mm deposited per pass of the distributor. Though there is strong evidence that rotational speeds of 1 to 2 rev/hr (high SK) produces significant operational improvement, traditional distribution arms revolve at 1 to 5 rev/min (low SK).

On the average, one acre of *low-rate filter* (also referred to as *standard-rate filter*) is needed for each 20,000 people served. Trickling filters can remove 70 to 90% of the suspended solids, 65 to 85% of the BOD, and 70 to 95% of the bacteria. Although low-rate filters have rocks to a depth of 6 ft (1.8 m), most of the reduction occurs in the first few feet of bed, and organisms in the lower part of the bed may be in a near-starvation condition.

Due to the low concentration of carbonaceous material in the water near the bottom of the filter, nitrogenous bacteria produce a highly nitrified effluent from low-rate filters. With low-rate filters, the bed will periodically slough off (unload) parts of its slime coating. Therefore, sedimentation after filtering is necessary. *Filter flies* are a major problem with low-rate filters, since fly larvae are provided with an undisturbed environment in which to breed.

Since there are limits to the heights of trickling filters, longer contact times can be achieved by returning some of the collected filter water back to the filter. This is known as *recirculation* or *recycling*. Recirculation is also used to keep the filter medium from drying out and to smooth out fluctuations in the hydraulic loading.

High-rate filters are now in use in most facilities. The higher hydraulic loading flushes the bed and inhibits excess biological growth. High-rate stone filters may be only 3 to 6 ft (0.9 to 1.8 m) deep. The high rate is possible because much of the filter discharge is recirculated. With the high flow rates, fly larvae are washed out, minimizing the filter fly problem. Since the biofilm is less thick and provided with carbon-based nutrients at a high rate, the effluent is nitrified only when the filter experiences low loading.

Super high-rate filters (*oxidation towers*) using synthetic media may be up to 40 ft (12 m) tall. High-rate and super high-rate trickling filters may be used as *roughing filters*, receiving wastewater at high hydraulic or organic loading and providing intermediate treatment or the first step of a multistage biological treatment process.

A BOD balance around a filter with recirculation results in Eq. 29.7 in which S_i is the BOD applied to the filter by the diluted influent, S_{ps} is the BOD of the influent from the primary settling tank, and S_o is the BOD of the trickling filter effluent.

$$S_{ps} + RS_o = (1+R)S_i \qquad 29.7$$

$$S_i = \frac{S_{ps} + RS_o}{1+R} \qquad 29.8$$

BOD is reduced significantly in a trickling filter. Standard-rate filters produce an 80 to 85% reduction, and high-rate filters remove 65 to 80% of BOD, less because of reduced contact area and time. The *removal fraction* (*removal efficiency*) of a single-stage trickling filter is

$$\eta = \frac{S_{\text{removed}}}{S_i} = \frac{S_i - S_o}{S_i} \qquad 29.9$$

By definition, the *recirculation ratio*, R, is zero for standard-rate filters but can be as high as 4:1 for high-rate filters.

$$R = \frac{Q_r}{Q_w} \qquad 29.10$$

Filters may be classified as high-rate based on their hydraulic loading, organic loading, or both. The *hydraulic loading* of a trickling filter is the total water flow divided by the plan area. Typical values of hydraulic loading are 25 to 100 gal/day-ft^2 (1 to 4 m^3/day·m^2) for standard filters and 250 to 1000 gal/day-ft^2 (10 to 40 m^3/day·m^2) or higher for high-rate filters.

$$L_H = \frac{Q_w + Q_r}{A} = \frac{Q_w(1+R)}{A} \qquad 29.11$$

The *BOD loading* (*organic loading* or *surface loading*) is calculated without considering any recirculated flow. BOD loading for the filter/clarifier combination is essentially the BOD of the applied wastewater divided by the filter volume. BOD loading is typically given in pounds per 1000 ft^3 per day (hence the 1000 term in Eq. 29.12.) Typical values are 5 to 25 lbm/1000 ft^3-day (0.08 to 0.4 kg/m^3·day) for low-rate filters and 25 to 110 lbm/1000 ft^3-day (0.08 to 1.8 kg/m^3·day) for high-rate filters.

$$L_{\text{BOD}} = \frac{Q_{w,\text{MGD}} S_{\text{mg/L}} \left(8.345 \dfrac{\text{lbm-L}}{\text{MG-mg}}\right) (1000)}{V_{\text{ft}^3}} \qquad 29.12$$

The *specific area* of the filter is the total surface area of the exposed filter medium divided by the total volume of the filter.

Example 29.2

A single-stage trickling filter plant processes 1.4 MGD of raw domestic waste with a BOD of 170 mg/L. The

trickling filter is 90 ft in diameter and has river rock media to a depth of 7 ft. The recirculation rate is 50%, and the filter is classified as high-rate. Water passes through clarification operations both before and after the trickling filter operation. Determine if the trickling filter has been sized properly.

Solution

The filter area is

$$A = \frac{\pi}{4}D^2 = \left(\frac{\pi}{4}\right)(90\text{ ft})^2 = 6362\text{ ft}^2$$

The rock volume is

$$V = AZ = (6362\text{ ft}^2)(7\text{ ft}) = 44{,}534\text{ ft}^3$$

The hydraulic load for a high-rate filter should be 250 to 1000 gal/day-ft^2.

$$\begin{aligned} L_H &= \frac{Q_w(1+R)}{A} \\ &= \frac{\left(1.4 \times 10^6\ \frac{\text{gal}}{\text{day}}\right)(1+0.5)}{6362\text{ ft}^2} \\ &= 330\text{ gal/day-ft}^2 \quad \text{[OK]} \end{aligned}$$

The primary clarification process will remove approximately 30% of the BOD. The remaining BOD is

$$\begin{aligned} \text{BOD}_i &= (1-0.3)\left(170\ \frac{\text{mg}}{\text{L}}\right) \\ &= 119\text{ mg/L} \end{aligned}$$

The BOD loading should be approximately 30 to 90 lbm/1000 ft^3-day.

$$\begin{aligned} L_{\text{BOD}} &= \frac{Q_{w,\text{MGD}}\text{BOD}_{\text{mg/L}}\left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right)(1000)}{V_{\text{ft}^3}} \\ &= \frac{\left(1.4\ \frac{\text{MG}}{\text{day}}\right)\left(119\ \frac{\text{mg}}{\text{L}}\right) \times \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right)(1000)}{44{,}534\text{ ft}^3} \\ &= 31.2\text{ lbm/day-1000 ft}^3 \quad \text{[OK]} \end{aligned}$$

20. TWO-STAGE TRICKLING FILTERS

If a higher BOD and solids removal fraction is needed, two filters can be connected in series to form a *two-stage filter* system with an optional intermediate settling tank. The efficiency of the second-stage filter is considerably less than that of the first-stage filter because much of the biological food has been removed from the flow.

21. NATIONAL RESEARCH COUNCIL EQUATION

In 1946, the National Research Council (NRC) studied sewage treatment facilities at military installations. The wastewater at these facilities was stronger than typical municipal wastewater. Not surprisingly, the NRC concluded that the organic loading had a greater effect on removal efficiency than did the hydraulic loading.

If it is assumed that the biological layer and hydraulic loading are uniform, the water is at 20°C, and the filter is single-stage rock followed by a settling tank, then the *NRC equation*, Eq. 29.13, can be used to calculate the BOD removal fraction of the single-stage filter/clarifier combination. Inasmuch as installations with high BOD and low hydraulic loads were used as the basis of the studies, BOD removal efficiencies in typical municipal facilities are higher than predicted by Eq. 29.13. The value of L_{BOD} excludes recirculation returned directly from the filter outlet, which is accounted for in the value of F.

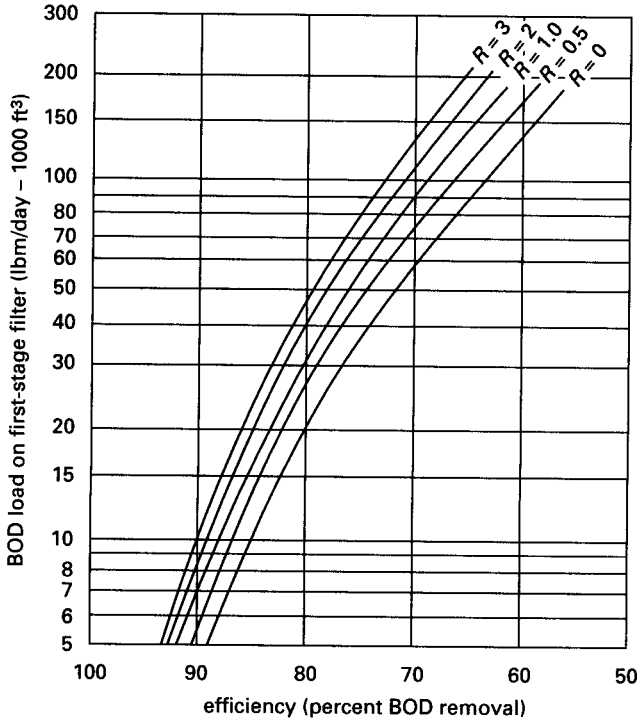
$$\eta = \frac{1}{1 + 0.0561\sqrt{\frac{L_{\text{BOD}}}{F}}} \qquad 29.13$$

It is important to recognize the BOD loading, L_{BOD} in Eq. 29.13, has units of lbm/day-1000 ft^3. The constant 0.0085 is often encountered in place of 0.0561 in the literature. However, this value is for use with media volumes expressed in lbm/ac-ft, not in thousands of ft^3.

$$\eta = \frac{1}{1 + 0.0085\sqrt{\frac{L_{\text{BOD,lbm/day}}}{V_{\text{ac-ft}}F}}} \qquad 29.14$$

There are a number of ways to recirculate water from the output of the trickling filters back to the filter. Water can be brought back to a wet well, to the primary settling tank, to the filter itself, or to a combination of the three. The variations in performance are not significant as long as sludge itself is not recirculated. Equation 29.13 can be used with any of the recirculation schemes.

F is the *effective number of passes* of the organic material through a filter. R is the ratio of filter discharge returned to the inlet to the raw influent. In Eq. 29.15, w is a weighting factor typically assigned a value of 0.1.



$$F = \frac{1+R}{(1+wR)^2} \qquad 29.15$$

It is time-consuming to extract the organic loading, L_{BOD}, from Eq. 29.13 given η and R. Figure 29.4 can be used for this purpose.

Based on the NRC model, the removal fraction for a two-stage filter with an intermediate clarifier is

$$\eta_2 = \frac{1}{1 + \left(\frac{0.0561}{1-\eta_1}\right)\sqrt{\frac{L_{\text{BOD}}}{F}}} \qquad 29.16$$

In recent years, the NRC equations have fallen from favor for several reasons. These reasons include applicability only to rock media, inability to correct adequately for temperature variations, inapplicability to industrial waste, and empirical basis.

[a]NRC model, single-stage

Figure 29.4 *Trickling Filter Performance*[a]

22. VELZ EQUATION

Equation 29.17, known as the *Velz equation*, was the first semi-theoretical analysis of trickling filter performance versus depth of media. It is useful in predicting the BOD removal fraction for any generic trickling filter, including those with synthetic media. The original Velz used the term "total removable fraction of BOD," though this is understood to mean the maximum fraction of removable BOD removed.

For filter depths in feet and operation at 29°C, typical values of the *Velz decay rate*, K, an empirical rate constant, are 0.175 ft^{-1} (0.574 m^{-1}) for low-rate filters and 0.1505 ft^{-1} (0.493 m^{-1}) for high-rate filters. These values are highly dependent on the installation and operating characteristics, particularly the hydraulic loading, which is not included in the formula.

$$\frac{\Delta S_i}{S_i} = \frac{S_i - S_o}{S_i} = 10^{-KZ} \qquad 29.17$$

Velz' values of K were given for 29°C. The variation in temperature was assumed to be

$$K_T = K_{20°C}(1.047)^{T-20°C} \qquad 29.18$$

23. MODERN FORMULATIONS

Various researchers have built upon the *Velz equation* and developed correlations of the form of Eq. 29.19 for various situations and types of filters. (In Eq. 29.19, S_a is the specific area, not the BOD.) Each researcher has used different nomenclature and assumptions. For example, the inclusion of the effects of dilution by recirculation is far from universal. The specific form of the equation, values of constants and exponents, temperature coefficients, limitations, and assumptions are needed before such a correlation can be reliably used.

$$\frac{S_o}{S_i} = \exp\left\{-KZS_a^m\left(\frac{A}{Q}\right)^n\right\} \qquad 29.19$$

As an example of the difficulty in finding one model that predicts all trickling filter performance, consider the BOD removal efficiency as predicted by the *Schulze correlation* (1960) for rock media and the *Germain correlation* (1965) for synthetic media. Though both correlations have the same form (Eq. 29.20), both measured filter depths in feet, and both expressed hydraulic loadings in gal/min-ft^2, the Schulze correlation included recirculation while the Germain correlation did not. The treatability constant, k, was 0.51 to 0.76 day^{-1} for the Schulze correlation and 0.088 day^{-1} for the Germain correlation. The *media factor* exponent, n, was 0.67 for the Schulze correlation (rock media) and 0.5 for the Germain correlation (plastic media).

$$\frac{S_o}{S_i} = \exp\left\{\frac{-kZ}{L_H^n}\right\} \qquad 29.20$$

24. ROTATING BIOLOGICAL CONTACTORS

Rotating biological contactors, RBCs (also known as *rotating biological reactors*), consist of large-diameter plastic disks, partially immersed in wastewater, on which biofilm is allowed to grow. The disks are mounted on shafts that turn slowly. The rotation progressively wets the disks, alternately exposing the biofilm to organic material in the wastewater and to oxygen in the air. The biofilm population, since it is well oxygenated, efficiently removes organic solids from the wastewater. RBCs are primarily used for carbonaceous BOD removal, although they can also be used for nitrification or a combination of both.

The primary design criterion is hydraulic loading, not organic (BOD) loading. For a specific hydraulic loading, the BOD removal efficiency will be essentially constant, regardless of variations in BOD. Other design criteria are listed in Table 29.11.

RBC operation is more efficient when several stages are used. Recirculation is not common with RBC processes. The process can be placed in series or in parallel with existing trickling filter or activated sludge processes.

Table 29.11 *Typical Characteristics of Rotating Biological Contactors*

number of stages	2–4
disk diameter	10–12 ft (3–3.6 m)
immersion, percentage of area	40%
hydraulic loading	
secondary treatment	2–4 gal/day-ft^2 (0.08–0.16 m^3/day·m^2)
tertiary treatment (nitrification)	0.75–2 gal/day-ft^2 (0.03–0.08 m^3/day·m^2)
optimum peripheral rotational speed	1 ft/sec (0.3 m/s)
tank volume	0.12 gal/ft^2 (0.0049 m^3/m^2) of biomass area
operating temperature	13–32°C
BOD removal fraction	70–80%

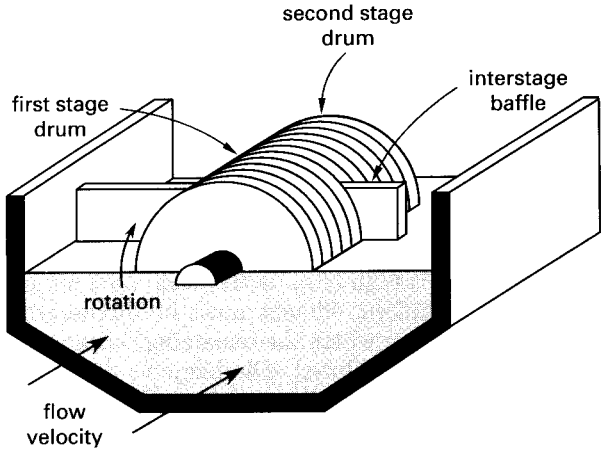


Figure 29.5 *Rotating Biological Contactor*

25. SAND FILTERS

For small populations, a *slow sand filter* (*intermittent sand filter*) can be used. Because of the lower flow rate, the filter area per person is higher than for a trickling filter. Roughly one acre is needed for each 1000 people. The filter is constructed as a sand bed 2 to 3 ft (0.6 to 0.9 m) deep over a 6 to 12 in (150 to 300 mm) gravel bed. The filter is alternately exposed to water from a settling tank and to air (hence the term intermittent). Straining and aerobic decomposition clean the water. Application rates are usually 2 to 2.5 gal/day-ft^2 (0.08 to 0.1 m^3/day·m^2). Up to 95% of the BOD can be satisfied in an intermittent sand filter. The filter is cleaned by removing the top layer of clogged sand.

If the water is applied continuously as a final process following secondary treatment, the filter is known as a *polishing filter* or *rapid sand filter*. The water rate of a polishing filter may be as high as 10 gal/day-ft^2 (0.4 m^3/day·m^2). Although the designs are similar to those used in water supply treatment, coarser media is used since the turbidity requirements are less stringent. Backwashing is required more frequently and is more aggressive than with water supply treatment.

26. INTERMEDIATE CLARIFIERS

Sedimentation tanks located between trickling filter stages or between a filter and subsequent aeration are known as *intermediate clarifiers* or *secondary clarifiers*. Typical characteristics of intermediate clarifiers used with trickling filter processes are: maximum overflow rate, 1000 gal/ft^2-day (41 m^3/day·m^2); minimum water depth, 7 ft (2.1 m); and maximum weir loading, 10,000 gal/day-ft (125 m^3/day·m) for plants processing 1 MGD or less and 15,000 gal/day-ft (185 m^3/day·m) for plants processing over 1 MGD.

27. FINAL CLARIFIERS

Sedimentation following secondary treatment occurs in *final clarifiers*. The purpose of final clarification is to collect sloughed-off material from trickling filter processes or to collect sludge and return it for activated sludge processes. The minimum depth is approximately 7 ft (2.1 m), and the maximum overflow rate is approximately 800 gal/day-ft^2 (32 m^3/day·m^2). The maximum weir loading is the same as for intermediate clarifiers, but the lower rates are preferred.

28. PHOSPHOROUS REMOVAL: PRECIPITATION

Phosphorous concentrations of 5 to 15 mg/L (as P) are experienced in untreated wastewater, most of which originates from synthetic detergents and human waste. Approximately 10% of the total phosphorous is insoluble and can be removed in primary settling. The amount that is removed by absorption in conventional biological processes is small. The remaining phosphorous is soluble and must be removed by converting it into an insoluble precipitate.

Soluble phosphorous is removed by precipitation and settling. Aluminum sulfate, ferric chloride ($FeCl_3$), and lime may be used depending on the nature of the phosphorous radical. Aluminum sulfate is more desirable since lime reacts with hardness and forms large quantities of additional precipitates. (Hardness removal is not as important as in water supply treatment.) However, the process requires about 10 pounds (10 kilograms) of aluminum sulfate for each pound (kilogram) of phosphorous removed. The process also produces a chemical sludge that is difficult to dewater, handle, and dispose of.

$$Al_2(SO_4)_3 + 2PO_4 \leftrightarrow 2AlPO_4 + 3SO_4 \qquad 29.21$$

$$FeCl_3 + PO_4 \leftrightarrow FePO_4 + 3Cl \qquad 29.22$$

Due to the many other possible reactions the compounds can participate in, the dosage should be determined from testing. The stoichiometric chemical reactions describe how the phosphorous is removed, but they do not accurately predict the quantities of coagulants needed.

29. AMMONIA REMOVAL: AIR STRIPPING

Ammonia may be removed by either biological processing or air stripping. In the biological *nitrification and denitrification process*, ammonia is first aerobically converted to nitrite and then to nitrate (nitrification) by bacteria. Then, the nitrates are converted to nitrogen gas, which escapes (denitrification).

In the *air-stripping* (*ammonia-stripping*) method, lime is added to water to increase its pH to about 10. This causes the ammonium ions, NH_4^+, to change to dissolved ammonia gas, NH_3. The water is passed through a packed tower into which air is blown at high rates. The air strips the ammonia gas out of the water. Recarbonation follows to remove the excess lime.

30. CARBON ADSORPTION

Adsorption uses high surface-area activated carbon to remove organic contaminants. Adsorption can use *granular activated carbon* (GAC) in column or fluidized-bed reactors or *powdered activated carbon* (PAC) in complete-mix reactors. Activated carbon is relatively nonspecific, and it will remove a wide variety of refractory organics as well as some inorganic contaminants. It should generally be considered for organic contaminants that are nonpolar, have low solubility, or have high molecular weights.

The most common problems associated with columns are breakthrough, excessive headloss due to plugging, and premature exhaustion. *Breakthrough* occurs when the carbon becomes saturated with the target compound and can hold no more. *Plugging* occurs when biological growth blocks the spaces between carbon particles. *Premature exhaustion* occurs when large and high molecular-weight molecules block the internal pores in the carbon particles. These latter two problems can be prevented by locating the carbon columns downstream of filtration.

31. CHLORINATION

Chlorination to disinfect and deodorize is one of the final steps prior to discharge. Vacuum-type feeders are used predominantly with chlorine gas. Chlorine under vacuum is combined with wastewater to produce a chlorine solution. A *flow-pacing* chlorinator will reduce the chlorine solution feed rate when the wastewater flow decreases (e.g., at night).

The size of the *contact tank* is variable, depending on economics and other factors. An average design detention time is 30 min at average flow, some of which can occur in the plant outfall after the contact basin. Contact tanks are baffled to prevent short-circuiting that would otherwise reduce chlorination time and effectiveness.

Alternatives to disinfection by chlorine include sodium hypochlorite, ozone, ultraviolet light, bromine (as bromine chloride), chlorine dioxide, and hydrogen peroxide. All alternatives have one or more disadvantages when compared to chlorine gas.

32. DECHLORINATION

Toxicity, by-products, and strict limits on *total residual oxidants* (TROs) now make dechlorination mandatory at many installations. Sulfur dioxide (SO_2) and sodium thiosulfite ($Na_2S_2SO_3$) are the primary compounds used as dechlorinators today. Other compounds seeing limited use are sodium metabisulfate ($Na_2S_2O_5$), sodium bisulfate ($NaHSO_3$), sodium sulfite (Na_2SO_3), hydrogen peroxide (H_2O_2), and granular activated carbon.

Though reaeration was at one time thought to replace oxygen in water depleted by sulfur dioxide, this is now known to be false.

33. EFFLUENT DISPOSAL

Organic material and bacteria present in wastewater are generally not removed in their entireties, though the removal efficiency is high (e.g., better than 95% for some processes). Therefore, effluent must be discharged to large bodies of water where the remaining contaminants can be substantially diluted. Discharge to flowing surface water and oceans is the most desirable. Discharge to lakes and reservoirs should be avoided.

In some areas, *combined sewer overflow* (CSO) outfalls still channel wastewater into waterways during heavy storms when treatment plants are overworked. Such pollution can be prevented by the installation of large retention basins (*diversion chambers*), miles of tunnels, reservoirs to capture overflows for later controlled release to treatment plants, screening devices to separate solids from wastewater, swirl concentrators to capture solids for treatment while permitting the clearer portion to be chlorinated and released to waterways, and more innovative vortex solids separators.

34. WASTEWATER RECLAMATION

Treated wastewater can be used for irrigation, firefighting, road maintenance, or flushing. Public access to areas where reclaimed water is disposed of through spray-irrigation (e.g., in sod farms, fodder crops, and pasture lands) should be restricted. When the reclaimed water is to be used for irrigation of public areas, the water quality standards regarding suspended solids, fecal coliforms, and viruses should be strictly controlled.

Although it has been demonstrated that wastewater can be made potable at great expense, such practice has not gained widespread favor.

PRACTICE PROBLEMS

Lagoons

1. A cheese factory located in a normally warm state has liquid waste with the following characteristics.

waste no. 1	
volume	10,000 gal/day
BOD	1000 mg/L
waste no. 2	
volume	25,000 gal/day
BOD	250 mg/L

The factory will use a 4 ft deep on-site lagoon to stabilize the waste.

(a) What is the total BOD loading?

(A) 60 lbm/day
(B) 85 lbm/day
(C) 110 lbm/day
(D) 140 lbm/day

The answer is (D).

(b) What lagoon size is required?

(A) 2.7 ac
(B) 6.8 ac
(C) 8.3 ac
(D) 10.9 ac

The answer is (B).

(c) What is the detention time?

(A) 5 wk
(B) 14 wk
(C) 36 wk
(D) 52 wk

The answer is (C).

Trickling Filters

2. It is estimated that the BOD of raw sewage received at a treatment plant serving a population of 20,000 will be 300 mg/L. It is estimated that the per capita BOD loading is 0.17 lbm. 30% of the influent BOD is removed by settling. One single-stage high-rate trickling filter is to be used to reduce the plant effluent to 50 mg/L. Recirculation is from the filter effluent to the primary settling influent. *Ten States' Standards* are in effect.

(a) What is the design flow rate?

(A) 0.9 MGD
(B) 1.1 MGD
(C) 1.4 MGD
(D) 2.0 MGD

The answer is (C).

(b) Assuming a design flow rate of 1.35 MGD, what is the total organic load on the filter?

(A) 1700 lbm/day
(B) 2100 lbm/day
(C) 2400 lbm/day
(D) 3400 lbm/day

The answer is (C).

(c) Assuming an incoming volume of 1.35 MGD and an organic loading of 60 lbm/day-1000 ft^3, what volume should be recirculated?

(A) 0.6 MGD
(B) 0.9 MGD
(C) 1.2 MGD
(D) 2.2 MGD

The answer is (D).

(d) What is the overall plant efficiency?

(A) 45%
(B) 76%
(C) 83%
(D) 91%

The answer is (C).

3. The average wastewater flow from a community of 20,000 is 125 gpcd. The 5 day, 20°C BOD is 250 mg/L. The suspended solids content is 300 mg/L. A final plant effluent of 50 mg/L of BOD is to be achieved through the use of settling tanks and two identical trickling filters operating in parallel. The settling tanks are to be designed to a standard of 1000 gpd/ft^2. The trickling filters are to be 6 ft deep and designed for an organic loading of 50.8 lbm/day-1000 ft^3. There is no recirculation.

(a) What settling tank surface area is required?

(A) 2500 ft^2
(B) 3000 ft^2
(C) 3500 ft^2
(D) 4500 ft^2

The answer is (A).

(b) What settling tank diameter is required?

(A) 40 ft
(B) 50 ft
(C) 65 ft
(D) 80 ft

The answer is (A).

(c) Estimate the BOD removal in the settling tanks.

(A) 15%
(B) 30%
(C) 45%
(D) 60%

The answer is (B).

Environmental

(d) What is the trickling filter diameter?
(A) 60 ft
(B) 70 ft
(C) 80 ft
(D) 90 ft

The answer is (D).

4. Wastewater from a city with a population of 40,000 has an average daily flow of 4.4 MGD. The sewage has the following characteristics.

BOD_5 at 20°C	160 mg/L
COD	800 mg/L
total solids	900 mg/L
suspended solids	180 mg/L
volatile solids	320 mg/L
settleable solids	8 mg/L
pH	7.8

The wastewater is to be treated with primary settling and secondary trickling filtration. The settling basins are to be circular, 8 ft deep, and designed to a standard overflow rate of 1000 gal/day-ft^2.

(a) Assuming two identical basins operating in parallel, what should be the diameter of each sedimentation basin in order to remove about 30% of the BOD?
(A) 45 ft
(B) 53 ft
(C) 77 ft
(D) 86 ft

The answer is (B).

(b) What is the detention time?
(A) 1.4 hr
(B) 1.8 hr
(C) 2.3 hr
(D) 3.1 hr

The answer is (A).

(c) What is the weir loading?
(A) 8200 gal/day-ft
(B) 11,000 gal/day-ft
(C) 13,000 gal/day-ft
(D) 15,000 gal/day-ft

The answer is (C).

5. (*Time limit: one hour*) A small community has a projected average flow of 1 MGD. Incoming wastewater has the following properties: BOD, 250 mg/L; grit specific gravity, 2.65; and total suspended solids, 400 mg/L. The community wants to have a wastewater treatment plant consisting of a single aerated grit chamber, a single primary clarifier, two identical circular trickling filters, and a single secondary clarifier. Recirculation will be 100%. The final effluent is to have a BOD of 30 mg/L.

(a) What is the peak design flow at the grit chamber?
(A) 1.0 MGD
(B) 1.5 MGD
(C) 2.0 MGD
(D) 2.5 MGD

The answer is (C).

(b) Determine the aerated grit chamber width assuming a 3 min detention time, 20 ft length, and a width:depth ratio of 1.25.
(A) 4 ft
(B) 6 ft
(C) 8 ft
(D) 10 ft

The answer is (B).

(c) Determine the approximate air requirements for the grit chamber in order to capture approximately 95% of the grit.
(A) 60 cfm
(B) 140 cfm
(C) 280 cfm
(D) 420 cfm

The answer is (A).

(d) If the clarifier is 12 ft deep, what should be its diameter?
(A) 50 ft
(B) 56 ft
(C) 63 ft
(D) 81 ft

The answer is (A).

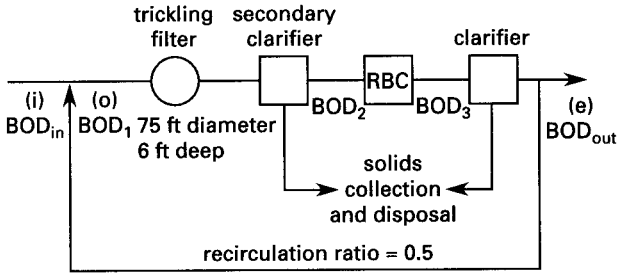
(e) What is the peak flow experienced by the trickling filters?
(A) 1.0 MGD
(B) 1.5 MGD
(C) 2.0 MGD
(D) 3.0 MGD

The answer is (C).

(f) Determine the diameter of the trickling filters assuming a 6 ft deep rock bed.
(A) 45 ft
(B) 55 ft
(C) 65 ft
(D) 85 ft

The answer is (D).

(g) Determine the diameter of the final clarifier.



(A) 40 ft
(B) 50 ft
(C) 60 ft
(D) 80 ft

The answer is (A).

Recirculating Biological Contactors

6. (*Time limit: one hour*) 1.5 MGD of wastewater with a BOD of 250 mg/L is processed by a high-rate rock trickling filter followed by recirculating biological contactor (RBC) processing. The trickling filter is 75 ft in diameter and 6 ft deep and was designed to NRC standards. The BOD removal efficiency of the RBC process is given by the following equation. (k has a value of 2.45 gal/day-ft^2, and Q (in units of gal/day) does not include recirculation.)

$$\eta_{BOD} = \frac{1}{\left(1 + \frac{kA}{Q}\right)^3}$$

(a) What exposed RBC surface area is required to achieve an effluent BOD_{out} of 30 mg/L?

(A) 4.2×10^4 ft^2
(B) 8.4×10^4 ft^2
(C) 1.3×10^5 ft^2
(D) 1.6×10^5 ft^2

The answer is (C).

(b) The recirculation pick-up point is relocated from after the final clarifier to after the trickling filter. The efficiency of the RBC process is 50%. Determine the recirculation ratio such that BOD_{out} is 30 mg/L.

(A) 25%
(B) 50%
(C) 75%
(D) 100%

The answer is (B).

(c) If $BOD_2 = 85$ mg/L, $BOD_{out} = 30$ mg/L, the yield is 0.4 lbm/lbm BOD removed, and the sludge specific gravity is essentially 1.0, what is the approximate sludge volume produced from the clarifiers?

(A) 4 ft^3/day
(B) 12 ft^3/day
(C) 21 ft^3/day
(D) 35 ft^3/day

The answer is (A).

1. SLUDGE

Sludge is the mixture of water, organic and inorganic solids, and treatment chemicals that accumulates in settling tanks. The term is also used to refer to the dried residue (screenings, grit, filter cake, and drying bed scraping) from separation and drying processes, although the term *biosolids* is becoming more common in this regard. (The term *residuals* is also used, though this term more commonly refers to sludge from water treatment plants.)

2. ACTIVATED SLUDGE PROCESS

The *activated sludge process* is a secondary biological wastewater treatment technique in which a mixture of wastewater and sludge solids is aerated. The sludge mixture produced during this oxidation process contains an extremely high concentration of aerobic bacteria, most of which are near starvation. This condition makes the sludge an ideal medium for the destruction of any organic material in the mixture. Since the bacteria are voraciously active, the sludge is called *activated sludge.*

The well-aerated mixture of wastewater and sludge, known as *mixed liquor*, flows from the aeration tank to a secondary clarifier where the sludge solids settle out. Most of the settled sludge solids are returned to the aeration tank in order to maintain the high population of bacteria needed for rapid breakdown of the organic material. However, because more sludge is produced than is needed, some of the return sludge is diverted ("wasted") for subsequent treatment and disposal. This wasted sludge is referred to as *waste activated sludge*, WAS. The volume of sludge returned to the aeration basin is typically 20 to 30% of the wastewater flow. The liquid fraction removed from the secondary clarifier weir is chlorinated and discharged.

Though diffused aeration and mechanical aeration are the most common methods of oxygenating the mixed liquor, various methods of staging the aeration are used, each having its own characteristic ranges of operating parameters.

In a traditional activated sludge plant using conventional aeration, the wastewater is typically aerated for 6 to 8 hr in long, rectangular aeration basins. Sufficient air, about eight volumes for each volume of wastewater treated, is provided to keep the sludge in suspension. The air is injected near the bottom of the aeration tank through a system of diffusers.

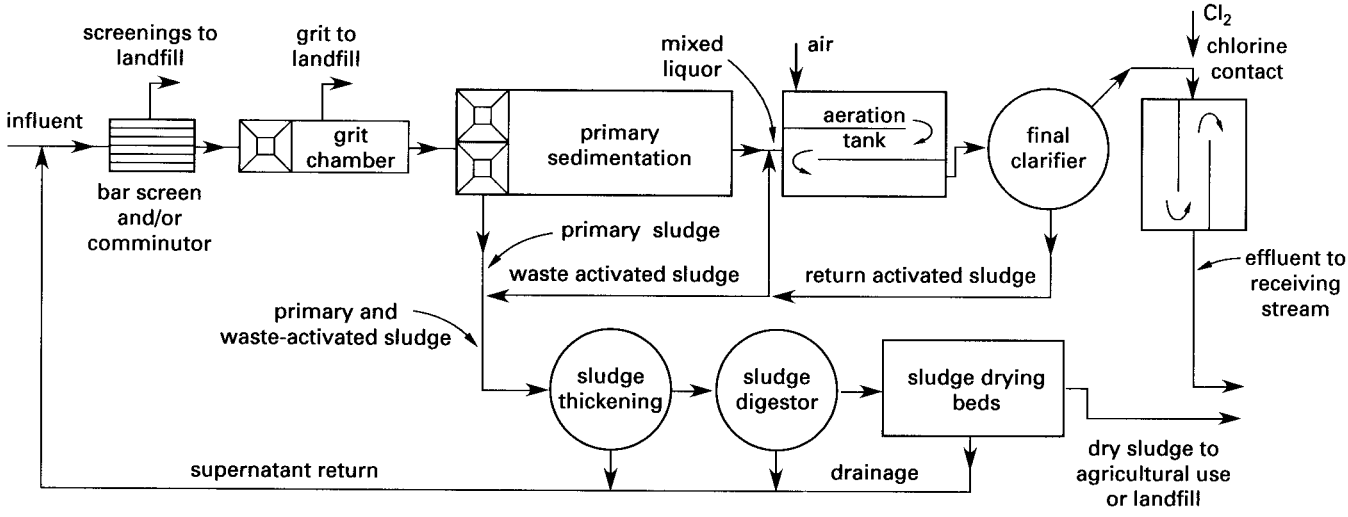

Figure 30.1 *Typical Activated Sludge Plant*

Table 30.1 *Conventional Activated Sludge Plants Typical Characteristics*[a]

BOD reduction	90–95%
effluent BOD	5–30 mg/L
effluent COD	15–90 mg/L
effluent suspended solids	5–30 mg/L
F:M	0.2–0.5
maximum aeration chamber volume	5000 ft^3 (140 m^3)
aeration chamber depth	10–15 ft (3–4.5 m)
aeration chamber width	20 ft (6 m)
length:width ratio	5:1 or greater
aeration air rate	0.5–2 ft^3 air/gal raw wastewater (3.6–14 m^3/m^3)
minimum dissolved oxygen	1 mg/L
MLSS	1000–4000 mg/L
sludge volume index	50–150
settling basin depth	15 ft (4.5 m)
settling basin detention time	4–8 hr
basin overflow rate	400–2000 gal/day-ft^2; 1000 gal/day-ft^2 typical (16–81 m^3/day·m^2; 40 m^3/day·m^2 typical)
settling basin weir loading	10,000 gal/day-ft (130 m^3/day·m)
fractional sludge recycle	0.20–0.30
frequency of sludge recycle	hourly

[a]See Table 30.2 for additional information.

3. AERATION STAGING METHODS

Small wastewater quantities can be treated with *extended aeration.* This method uses mechanical floating or fixed subsurface aerators to oxygenate the mixed liquor for 24 to 36 hr in a large lagoon. There is no primary clarification, and there is generally no sludge wasting process. Sludge is allowed to accumulate at the bottom of the lagoon for several months. Then the system is shut down and the lagoon is pumped out. Sedimentation basins are sized very small, with low overflow rates of 200 to 600 gal/day-ft^2 (8.1 to 24 m^3/day·m^2) and long retention times.

An *oxidation ditch* is a type of extended aeration system, configured in a continuous long and narrow oval. The basin contents circulate continuously to maintain mixing and aeration. Mixing occurs by brush aerators or a combination of low-head pumping and diffused aeration.

In *conventional aeration*, the influent is taken from a primary clarifier and then aerated. The amount of aeration is usually decreased as the wastewater travels along the aeration path since the BOD also decreases along the route. This is known as *tapered aeration.*

With *step-flow aeration*, aeration is constant along the length of the aeration path, but influent is introduced at various points along the path.

With *complete-mix aeration*, wastewater is added uniformly and the mixed liquor is removed uniformly over the length of the tank. The mixture is essentially uniform in composition throughout.

Units for the *contact stabilization* (*biosorption*) process are typically factory-built and brought to the site for installation, although permanent facilities can be built for the same process. Prebuilt units are compact but not as economical or efficient as larger plants running on the same process. The aeration tank is called a *contact tank.* The *stabilization tank* takes the sludge from the clarifier and aerates it. With this process, colloidal solids are absorbed in the activated sludge during the 30 to 90 min of aeration in the contact tank. Then, the sludge is removed by clarification and the return sludge is aerated for 3 to 6 more hours in the stabilization tank. Less time and space is required for this process because the sludge stabilization is done while the sludge is still concentrated. This method is very efficient in handling colloidal wastes.

The *high-rate aeration* method uses mechanical mixing along with aeration to decrease the aeration period and increase the BOD load per unit volume.

The *high purity oxygen aeration* method requires the use of bottled or manufactured oxygen that is introduced into closed/covered aerating tanks. Mechanical mixers are needed to take full advantage of the oxygen supply because little excess oxygen is provided. Retention times in aeration basins are longer than for other aerobic systems, producing higher concentrations of MLSS and better stabilization of sludge that is ultimately wasted. This method is applicable to high-strength sewage and industrial wastewater.

Sequencing batch reactors (SBRs) operate in a fill-and-drain sequence. The reactor is filled with influent, contents are aerated, and sludge is allowed to settle. Effluent is drawn from the basin along with some of the settled sludge, and new effluent is added to repeat the process. The "return sludge" is the sludge that remains in the basin.

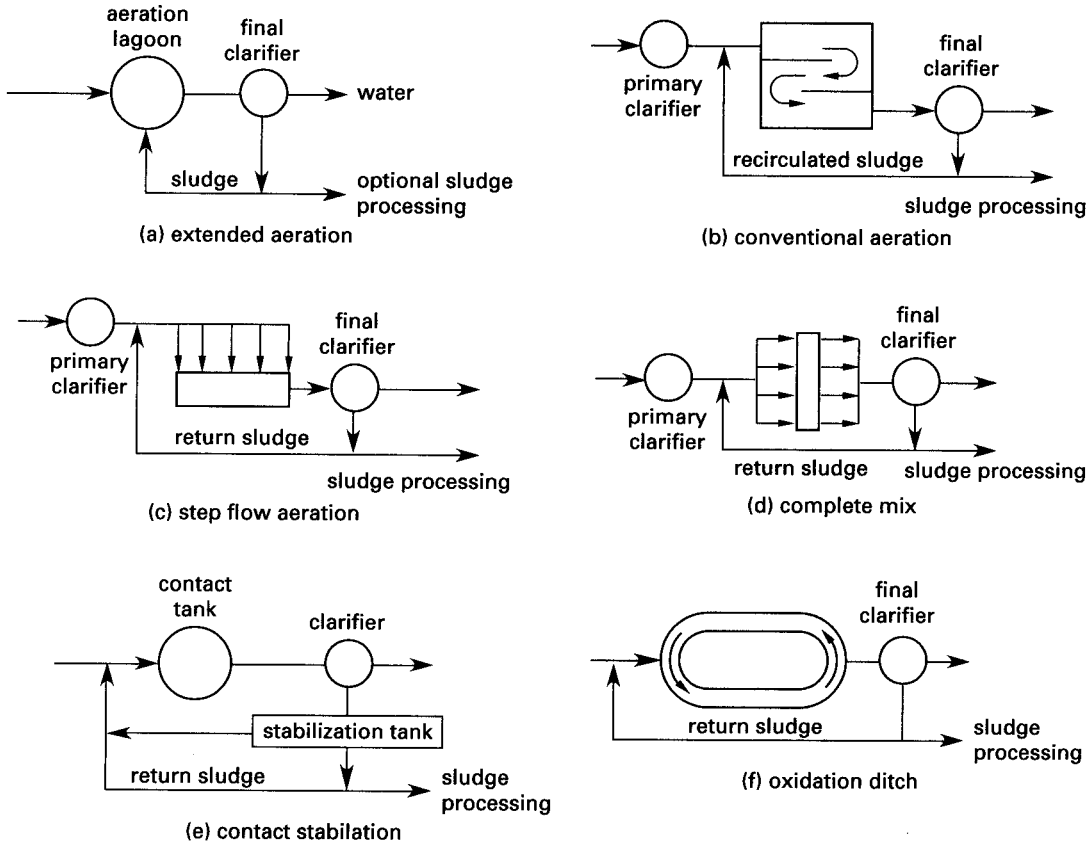

Figure 30.2 *Methods of Aeration*

Table 30.2 *Representative Operating Conditions for Aeration*[a]

type of aeration	plant flow rate (MGD)	θ_c (hr)	oxygen required (lbm/lbm BOD removed)	waste sludge (lbm/lbm BOD removed)	total plant BOD load (lbm/day)	aerator BOD load, L_{BOD} (lbm/day-1000 ft^3)	F:M (lbm/lbm-day)	MLSS (mg/L)	R (%)	η_{BOD} (%)

Environmental

4. FINAL CLARIFIERS

Table 30.4 lists typical operating characteristics for clarifiers in activated sludge processes. Sludge should be removed rapidly from the entire bottom of the clarifier.

Table 30.4 *Characteristics of Final Clarifiers for Activated Sludge Processes*

type of aeration	design flow (MGD)	minimum detention time (hr)	maximum overflow rate (gpd/ft^2)
conventional, high rate and step	< 0.5	3.0	600
	0.5–1.5	2.5	700
	> 1.5	2.0	800
contact stabilization	< 0.5	3.6	500
	0.5–1.5	3.0	600
	> 1.5	2.5	700
extended aeration	< 0.05	4.0	300
	0.05–0.15	3.6	300
	> 0.15	3.0	600

(Multiply MGD by 0.0438 to obtain m^3/s.)
(Multiply gal/day-ft^2 by 0.0407 m^3/day·m^2.)

5. SLUDGE PARAMETERS

The bacteria and other suspended material in the mixed liquor is known as *mixed liquor suspended solids* (MLSS) and is measured in mg/L. Suspended solids are further divided into fixed solids and volatile solids. *Fixed solids* (also referred to as *nonvolatile solids*) are those inert solids that are left behind after being fired in a furnace. *Volatile solids* are essentially those carbonaceous solids that are consumed in the furnace. The volatile solids are considered to be the measure of solids capable of being digested. Approximately 60 to 75% of sludge solids are volatile. The volatile material in the mixed liquor is known as the *mixed liquor volatile suspended solids* (MLVSS).

The organic material in the incoming wastewater constitutes "food" for the activated organisms. The food arrival rate is given by Eq. 30.1. S_o is usually taken as the incoming BOD_5, although COD is used in rare situations.

$$F = S_o Q_o \qquad 30.1$$

The mass of microorganisms is determined from the *volatile suspended solids concentration*, X, in the aeration tank.

$$M = V_a X \qquad 30.2$$

The *food-to-microorganism* (F:M) *ratio* is given by Eq. 30.3. For conventional aeration, typical values are 0.20 to 0.50 lbm/lbm-day (0.20 to 0.50 kg/kg·day), though values between 0.05 and 1.0 have been reported. θ in Eq. 30.3 is the *hydraulic detention time*.

$$\text{F:M} = \frac{S_{o,\text{mg/L}} Q_{o,\text{MGD}}}{V_{a,\text{MG}} X_{\text{mg/L}}} = \frac{S_{o,\text{mg/L}}}{\theta_{\text{days}} X_{\text{mg/L}}} \qquad 30.3$$

Some authorities include the entire suspended solids content (MLSS), not just the volatile portion (X), when calculating the food-to-microorganism ratio, although this interpretation is less common.

$$\text{F:M} = \frac{S_{o,\text{mg/L}} Q_{o,\text{MGD}}}{V_{a,\text{MG}} \text{MLSS}_{\text{mg/L}}} \qquad 30.4$$

The liquid fraction of the wastewater passes through an activated sludge process in a matter of hours. However, the sludge solids are recycled continuously and have an average stay much longer in duration. There are two measures of *sludge age*: the *mean cell residence time* (also known as the *age of the suspended solids* and *solids residence time*), essentially the age of the microorganisms, and *age of the BOD*, essentially the age of the food. For conventional aeration, typical values of the mean cell residence time are 6 to 15 days for high-quality effluent and sludge.

$$\theta_c = \frac{V_a X}{Q_e X_e + Q_w X_w} \qquad 30.5$$

The *BOD sludge age* (*age of the BOD*) is the reciprocal of the food-to-microorganism ratio.

$$\theta_{\text{BOD}} = \frac{1}{\text{F:M}} = \frac{V_{a,\text{MG}} X_{\text{mg/L}}}{S_{o,\text{mg/L}} Q_{o,\text{MGD}}} \qquad 30.6$$

The *sludge volume index* (SVI) is a measure of the sludge's settleability. SVI can be used to determine the tendency toward *sludge bulking*. (See Sec. 13.) SVI is determined by taking 1 L of mixed liquor and measuring the volume of settled solids after 30 min. SVI is the volume in mL occupied by 1 g of settled volatile and nonvolatile suspended solids.

$$\text{SVI} = \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) V_{\text{settled,mL/L}}}{\text{MLSS}_{\text{mg/L}}} \qquad 30.7$$

The total suspended solids concentration in the recirculated sludge can be found from Eq. 30.8. This equation is useful in calculating the solids concentration for any sludge that is wasted from the return sludge line. (Suspended sludge solids wasted include both fixed and volatile portions.)

$$\text{MLSS}_{\text{mg/L}} = \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right)\left(1000 \frac{\text{mL}}{\text{L}}\right)}{\text{SVI}_{\text{mL/g}}} \qquad 30.8$$

6. SOLUBLE BOD ESCAPING TREATMENT

S is a variable used to indicate the growth-limiting substrate in solution. Specifically, S (without a subscript) is defined as the soluble BOD_5 escaping treatment (i.e., the effluent BOD_5 leaving the activated sludge process). This may need to be calculated from the effluent suspended solids and the fraction, G, of the suspended solids that is ultimately biodegradable.

$$\begin{aligned}\text{BOD}_e &= \text{BOD}_{\text{escaping treatment}} + \text{BOD}_{\text{effluent suspended solids}} \\ &= S + S_e \\ &= S + 1.42 f G X_e\end{aligned} \qquad 30.9$$

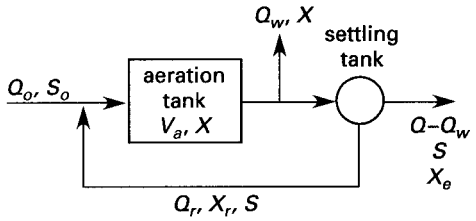
Care must be taken to distinguish between the standard five-day BOD and the ultimate BOD. The ratio of these two parameters, typically approximately 70%, is

$$f = \frac{\text{BOD}_5}{\text{BOD}_u} \qquad 30.10$$

In some cases, the terms in the product $1.42fG$ in Eq. 30.9 are combined, and S_e is known directly as a percentage of X_e. However, this format is less common.

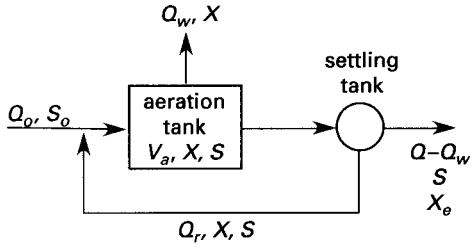
7. PROCESS EFFICIENCY

The *treatment efficiency* (*BOD removal efficiency*, *removal fraction*, etc.), typically 90 to 95% for conventional aeration, is given by Eq. 30.11. S_o is the BOD as received from the primary settling tank. If the overall plant efficiency is wanted, the effluent S is taken as the total BOD_5 of the effluent. Depending on convention, efficiency can also be based on only the soluble BOD escaping treatment (i.e., S from Eq. 30.9).



$$\eta_{\text{BOD}} = \frac{S_o - S}{S_o} \qquad 30.11$$

8. PLUG FLOW AND STIRRED TANK MODELS



Conventional aeration and complete-mix aeration represent two extremes for continuous-flow reactions. Ideal conventional aeration is described by a *plug-flow reaction* (PFR, also known as *tubular flow*) kinetic model. (The term *reactor* is commonly used to describe the aeration tank.) In a plug-flow reactor, material progresses along the reaction path, changing in composition as it goes. Mixing is considered to be ideal in the lateral plane but totally absent in the longitudinal direction. That is, the properties (in this case, BOD and suspended solids) change along the path, as though only a "plug" of material was progressing forward.

A complete-mix aerator, however, is a type of *continuous-flow stirred tank reactor* (CSTR or CFSTR). In a CSTR model, the material is assumed to be homogeneous in properties throughout as a result of continuous perfect mixing. It is assumed that incoming material is immediately diluted to the tank concentration, and the outflow properties are the same as the tank properties.

Modifications of the basic kinetic models are made to account for return/recycle and wastage. Many, but not all, of the same equations can be used to describe the performance of both the PFR and CSTR models.

(a) plug flow reactor with recycle

(b) continuously stirred tank reactor with recycle

Figure 30.3 *Kinetic Model Process Variables*

Until the late 1950s, nearly all activated sludge aeration tanks were long and narrow with length-to-width ratios greater than 5, and performance was assumed to be predicted by PFR equations. However, extensive testing has shown that substantial longitudinal mixing actually occurs, and many conventional systems are actually CSTRs. In fact, the long basin configuration gives an oxidation ditch the attributes of a PFR while maintaining CSTR characteristics.

The kinetic model for the PFR is complex, but it can be simplified under certain conditions. If the ratio of $\theta_c/\theta > 5$, the concentration of microorganisms in the influent to the reactor (aeration tank) will be approximately the same as in the effluent from the reactor.

$$\frac{1}{\theta_c} = \frac{\mu_m(S_o - S)}{S_o - S + (1+R)K_s \ln\left(\frac{S_i}{S}\right)} - k_d \quad \text{[PFR only]} \qquad 30.12$$

The *maximum specific growth rate*, μ_m, is calculated from the first-order reaction constant, k.

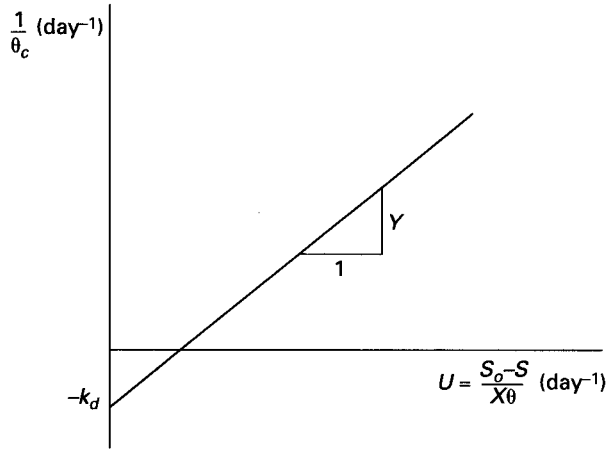
$$\mu_m = kY \qquad 30.13$$

The influent concentration after dilution with recycle flow is

$$S_i = \frac{S_o + RS}{1+R} \quad \text{[PFR only]} \qquad 30.14$$

The *rate of substrate utilization* as the waste passes through the aerating reactor is

$$r_{su} = \frac{-\mu_m SX}{Y(K_s + S)} \quad \text{[PFR only]} \qquad 30.15$$



For the CSTR, the *specific substrate utilization* (*specific utilization*), U, is the food-to-microorganism ratio multiplied by the fractional process efficiency.

$$U = \eta(\text{F:M}) = \frac{-r_{su}}{X} = \frac{S_o - S}{\theta X} \qquad 30.16$$

For the CSTR, the equivalent relationship between mean cell residence time, food-to-microorganism ratio, and specific utilization rate, U, is given by Eq. 30.17.

$$\frac{1}{\theta_c} = Y(\text{F:M})\eta - k_d = -Y\left(\frac{r_{su}}{X}\right) - k_d = YU - k_d \quad \text{[CSTR only]} \qquad 30.17$$

Y and k_d are the kinetic coefficients describing the bacterial growth process. Y is the *yield coefficient*, the mass of cells formed to the mass of substrate (food) consumed, in mg/mg. k_d is the *endogenous decay coefficient* (rate) of the microorganisms in day^{-1}. For a specified waste, biological community, and set of environmental conditions, Y and k_d are fixed. Equation 30.17 is a linear equation of the general form $y = mx+b$. Figure 30.4 illustrates how these coefficients can be determined graphically from bench-scale testing.

[a] As determined from bench-scale-activated sludge studies using a continuous flow stirred tank reactor without recycle

Figure 30.4 *Kinetic Growth Constants*[a]

For a continuously stirred tank reactor, the kinetic model predicts the effluent substrate concentration.

$$S = \frac{K_s(1 + k_d\theta_c)}{\theta_c(\mu_m - k_d) - 1} \quad \text{[CSTR only]} \qquad 30.18$$

The reactor volume, V_a, is

$$V_a = \theta Q_o = \frac{\theta_c Q_o Y(S_o - S)}{X(1 + k_d\theta_c)} \quad \text{[PFR and CSTR]} \qquad 30.19$$

The *hydraulic retention time*, θ, for the reactor is

$$\theta = \frac{V_a}{Q_o} \quad \text{[PFR and CSTR]} \qquad 30.20$$

The *hydraulic retention time*, θ, for the system is

$$\theta_s = \frac{V_a + V_s}{Q_o} \quad \text{[PFR and CSTR]} \qquad 30.21$$

The average concentration of microorganisms, X, in the reactor is

$$X = \frac{\left(\frac{\theta_c}{\theta}\right) Y(S_o - S)}{1 + k_d\theta_c} \quad \text{[PFR and CSTR]} \qquad 30.22$$

The *observed yield* is

$$Y_{\text{obs}} = \frac{Y}{1 + k_d\theta_c} \quad \text{[PFR and CSTR]} \qquad 30.23$$

The volatile portion of the mass of activated sludge that must be wasted each day is given by Eq. 30.24. The total (fixed and volatile) mass of sludge wasted each day must be calculated from the ratio of MLVSS and MLSS.

$$\begin{aligned} P_{x,\text{kg/day}} &= \frac{Q_{w,\text{m}^3/\text{day}} X_{r,\text{mg/L}}}{1000\ \frac{\text{g}}{\text{kg}}} \\ &= \frac{Y_{\text{obs,mg/mg}} Q_{o,\text{m}^3/\text{day}} (S_o - S)_{\text{mg/L}}}{1000\ \frac{\text{g}}{\text{kg}}} \end{aligned} \qquad 30.24$$

The sludge that must be wasted is reduced by the sludge that escapes in the clarifier effluent, which is ideally zero. The actual sludge solids escaping can be calculated as

$$m_{e,\text{solids}} = Q_e X_e \qquad 30.25$$

The *mean cell residence time* (see Eq. 30.5) can be calculated from Eq. 30.26. The sludge wasting rate, Q_w, can also be found from this equation. In most activated-sludge processes, waste sludge is drawn from the sludge recycle line. Therefore, Q_w is the *cell wastage rate* from the recycle line, and X_r is the microorganism concentration in the return sludge line.

$$\theta_c = \frac{V_a X}{Q_w X_r + Q_e X_e} = \frac{V_a X}{Q_w X_r + (Q_o - Q_w) X_e} \qquad 30.26$$

Since the average mass of cells in the effluent, X_e, is very small, Eq. 30.27 gives the mean cell residence time for sludge wastage from the return line. Centrifuge testing can be used to determine the ratio of X/X_r. (There is another reason for omitting X_e from the calculation: It may be too small to measure conveniently.)

$$\theta_c \approx \frac{V_a X}{Q_w X_r} \quad \text{[PFR and CSTR]} \qquad 30.27$$

For wastage directly from the aeration basin, $X_r = X$. In this case, Eq. 30.28 shows that the process can be controlled by wasting a flow equal to the volume of the aeration tank divided by the mean cell residence time.

$$\theta_c \approx \frac{V_a}{Q_w} \quad \text{[CSTR]} \qquad 30.28$$

9. ATMOSPHERIC AIR

Atmospheric air is a mixture of oxygen, nitrogen, and small amounts of carbon dioxide, water vapor, argon, and other inert gases. If all constituents except oxygen are grouped with the nitrogen, the air composition is as given in Table 30.5. It is necessary to supply by weight 1/0.2315 = 4.32 masses of air to obtain one mass of oxygen. The average molecular weight of air is 28.9.

Table 30.5 *Composition of Air*[a]

component	fraction by mass	fraction by volume
oxygen	0.2315	0.209
nitrogen	0.7685	0.791
ratio of nitrogen to oxygen	3.320	3.773[b]
ratio of air to oxygen	4.320	4.773

[a] Inert gases and CO_2 are included in N_2.
[b] This value is also reported by various sources as 3.76, 3.78, and 3.784.

10. AERATION TANKS

The *aeration period* is the same as the *hydraulic detention time* and is calculated without considering recirculation.

$$\theta = \frac{V_a}{Q_o} \qquad 30.29$$

The organic (BOD) *volumetric loading* rate (in kg BOD_5/day·m^3) for the aeration tank is

$$L_{\text{BOD}} = \frac{S_o Q_o}{V_a \left(1000\ \frac{\text{g}}{\text{kg}}\right)} \qquad 30.30$$

In the United States, volumetric loading is often specified in lbm/day-1000 ft^3.

$$L_{\text{BOD}} = \frac{S_{o,\text{mg/L}} Q_{o,\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) (1000)}{V_{a,\text{ft}^3}} \qquad 30.31$$

The *rate of oxygen transfer* from the air to the mixed liquor during aeration is given by Eq. 30.32. K_t is a macroscopic transfer coefficient that depends on the equipment and characteristics of the mixed liquor and

that has typical dimensions of 1/time. The dissolved oxygen deficit, D in mg/L, is given by Eq. 30.33. β is the mixed liquor's *oxygen saturation coefficient*, approximately 0.8 to 0.9. β corrects for the fact that the mixed liquor does not absorb as much oxygen as pure water does. The minimum dissolved oxygen content is approximately 0.5 mg/L, below which the processing would be limited by oxygen. However, a lower limit of 2 mg/L is typically specified.

$$\dot{m}_{\text{oxygen}} = K_t D \qquad 30.32$$

$$D = \beta \text{DO}_{\text{saturated water}} - \text{DO}_{\text{mixed liquor}} \qquad 30.33$$

The *oxygen demand* is given by Eq. 30.34. The factor 1.42 is the theoretical gravimetric ratio of oxygen required for carbonaceous organic material based on an ideal stoichiometric reaction. Equation 30.34 neglects nitrogenous demand, which can also be significant.

$$\dot{m}_{\text{oxygen,kg/day}} = \left(\frac{Q_{o,\text{m}^3/\text{day}}(S_o - S)_{\text{mg/L}}}{f}\right) - 1.42 P_{x,\text{kg/day}}$$

[PFR and CSTR] 30.34

Air is approximately 23.2% oxygen by mass. Considering a *transfer efficiency* of η_{transfer} (typically less than 10%), the air requirement is calculated from the oxygen demand.

$$\dot{m}_{\text{air}} = \frac{\dot{m}_{\text{oxygen}}}{0.232\eta_{\text{transfer}}} \qquad 30.35$$

The volume of air required is given by Eq. 30.36. The density of air is approximately 0.075 lbm/ft^3 (1.2 kg/m^3). Typical volumes for conventional aeration are 500 to 900 ft^3/lbm BOD_5 (30 to 55 m^3/kg BOD_5) for F:M ratios greater than 0.3 and 1200 to 1800 ft^3/lbm BOD_5 (75 to 115 m^3/kg BOD_5) for F:M ratios less than 0.3 day^{-1}. Air flows in SCFM (*standard cubic feet per minute*) are based on a temperature of 70°F (21°C) and pressure of 14.7 psia (101 kPa).

$$\dot{V}_{\text{air}} = \frac{\dot{m}_{\text{air}}}{\rho_{\text{air}}} \quad \text{[PFR and CSTR]} \qquad 30.36$$

Aeration equipment should be designed with an excess-capacity safety factor of 1.5 to 2.0. *Ten States' Standards* requires 200% of calculated capacity for air diffusion systems, which is assumed to be 1500 ft^3/lbm BOD_5 (94 m^3/kg BOD_5) [TSS-1997, 92.332].

The air requirement per unit volume (m^3/m^3, calculated using consistent units) is V_{air}/Q_o. The air requirement in m^3 per kilogram of soluble BOD_5 removed is

$$\frac{\dot{V}_{\text{air}}\left(1000\ \frac{\text{g}}{\text{kg}}\right)}{Q_o(S_o - S)} \qquad 30.37$$

Example 30.1

Mixed liquor (β = 0.9, DO = 3 mg/L) is aerated at 20°C. The transfer coefficient is 2.7 h^{-1}. What is the rate of oxygen transfer?

Solution

From App. 22.D, at 20°C, the saturated oxygen content of pure water is 9.2 mg/L. The oxygen deficit is found from Eq. 30.33.

$$\begin{aligned} D &= \beta \text{DO}_{\text{saturated water}} - \text{DO}_{\text{mixed liquor}} \\ &= (0.9)\left(9.2\ \frac{\text{mg}}{\text{L}}\right) - 3\ \frac{\text{mg}}{\text{L}} \\ &= 5.28\ \text{mg/L} \end{aligned}$$

The rate of oxygen transfer is found from Eq. 30.32.

$$\begin{aligned} \dot{m} &= K_t D = (2.7\ \text{h}^{-1})\left(5.28\ \frac{\text{mg}}{\text{L}}\right) \\ &= 14.3\ \text{mg/L·h} \end{aligned}$$

11. AERATION POWER AND COST

The work required to compress a unit mass of air from atmospheric pressure to the discharge pressure depends on the nature of the compression. Various assumptions can be made, but generally an *isentropic compression* is assumed. Inefficiencies (thermodynamic and mechanical) are combined into a single *compressor efficiency*, η_c, which is essentially an *isentropic efficiency* for the compression process.

The ideal power to compress a volumetric flow rate, $\dot{V}$, or mass flow rate, $\dot{m}$, from pressure p_1 to pressure p_2 in an isentropic steady-flow compression process is given by Eq. 30.38. k is the ratio of specific heats, which has a value of 1.4. c_p is the specific heat at constant pressure, which has a value of 0.24 Btu/lbm-°R (1005 J/kg·K). R_{air} is the specific gas constant, 53.3 ft-lbf/lbm-°R (287 J/kg·K). In Eq. 30.38, temperatures must be absolute. Volumetric and mass flow rates are per second.

$$\begin{aligned} P_{\text{ideal,kW}} &= -\left(\frac{k p_1 \dot{V}_1}{(k-1)\left(1000\ \frac{\text{W}}{\text{kW}}\right)}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \\ &= -\left(\frac{k\dot{m}R_{\text{air}}T_1}{(k-1)\left(1000\ \frac{\text{W}}{\text{kW}}\right)}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \\ &= -\left(\frac{c_p\dot{m}T_1}{1000\ \frac{\text{W}}{\text{kW}}}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \quad \text{[SI]} \qquad 30.38(a) \end{aligned}$$

$$\begin{aligned} P_{\text{ideal,hp}} &= -\left(\frac{k p_1 \dot{V}_1}{(k-1)\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \\ &= -\left(\frac{k\dot{m}R_{\text{air}}T_1}{(k-1)\left(550\ \frac{\text{ft-lbf}}{\text{hp-sec}}\right)}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \\ &= -\left(\frac{c_p J\dot{m}T_1}{550\ \frac{\text{ft-lbf}}{\text{hp-sec}}}\right)\left(1 - \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}}\right) \quad \text{[U.S.]} \qquad 30.38(b) \end{aligned}$$

The actual compression power is

$$P_{\text{actual}} = \frac{P_{\text{ideal}}}{\eta_c} \qquad 30.39$$

The cost of running the compressor for some duration, t, is

$$\text{total cost} = (C_{\text{kW-hr}})P_{\text{actual}}t \qquad 30.40$$

12. RETURN RATE/RECYCLE RATIO

For any given wastewater and treatment facility, the influent flow rate, BOD, and tank volume cannot be changed. Of all the variables appearing in Eq. 30.3, only the suspended solids can be controlled. Therefore, the primary process control variable is the amount of organic material in the wastewater. This is controlled by the sludge return rate. Equation 30.41 gives the sludge *return ratio* (*recycle ratio*), which is typically 0.20 to 0.30. (Some authorities use the symbol α to represent the recycle ratio.)

$$R = \frac{Q_r}{Q_o} \qquad 30.41$$

The actual recirculation rate can be found by writing a mass balance around the inlet to the reactor and solving for the recirculation rate, Q_r.

$$X(Q_o + Q_r) = X_r Q_r \qquad 30.42$$

$$\frac{Q_r}{Q_o + Q_r} = \frac{X_r}{X} \qquad 30.43$$

The theoretical required return rate can be calculated from the sludge volume index (SVI; see Sec. 5). Equation 30.44 assumes that the settling tank responds identically to the graduated cylinder used in the SVI test. Equations 30.43 and 30.44 are analogous.

$$\frac{Q_r}{Q_o + Q_r} = \frac{V_{\text{settled,mL/L}}}{1000\ \frac{\text{mL}}{\text{L}}} \qquad 30.44$$

$$R = \frac{V_{\text{settled,mL/L}}}{1000\ \frac{\text{mL}}{\text{L}} - V_{\text{settled,mL/L}}} \qquad 30.45$$

Equation 30.45 is based on settling and represents a theoretical value, but it does not necessarily correspond to the actual recirculation rate. Greater-than-necessary recirculation returns clarified liquid unnecessarily, and less recirculation leaves settled solids in the clarifier.

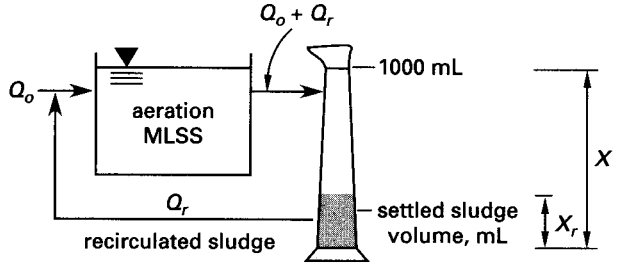


Figure 30.5 *Theoretical Relationship Between SVI Test and Return Rate*

Example 30.2

Two 1 L samples of mixed liquor are taken from an aerating lagoon. After settling for 30 min in a graduated cylinder, 250 mL of solids have settled out in the first sample. The total suspended solids concentration in the second sample is found to be 2300 mg/L. (a) What is the sludge volume index? (b) What is the theoretical required sludge recycle rate?

Solution

(a) Use Eq. 30.7.

$$\text{SVI} = \frac{1000 V_{\text{settled,mL/L}}}{X_{\text{mg/L}}} = \frac{\left(1000\ \frac{\text{mg}}{\text{g}}\right)\left(250\ \frac{\text{mL}}{\text{L}}\right)}{2300\ \frac{\text{mg}}{\text{L}}} = 109\ \text{mL/g}$$

(b) The theoretical required recycle rate is given by Eq. 30.45.

$$R = \frac{V_{\text{settled,mL/L}}}{1000 - V_{\text{settled,mL/L}}} = \frac{250\ \text{mL}}{1000\ \text{mL} - 250\ \text{mL}} = 0.33$$

Example 30.3

An activated sludge plant receives 4.0 MGD of wastewater with a BOD of 200 mg/L. The primary clarifier removes 30% of the BOD. The sludge is aerated for 6 hr. The oxygen transfer efficiency is 6%, and one pound of oxygen is required for each pound of BOD oxidized. The food-to-microorganism ratio is 0.33. The SVI is 100. 30% of the volatile solids (MLVSS) are wasted each day. The MLVSS/MLSS ratio is 0.7. The surface settling rate of the secondary clarifier is 800 gal/day-ft^2. The final effluent has a BOD of 10 mg/L.

What are the (a) secondary BOD removal fraction, (b) aeration tank volume, (c) MLSS, (d) total suspended solids content, (e) theoretical recirculation rate, (f) mass of MLSS wasted each day, (g) clarifier surface area, and (h) air requirements?

Solution

(a) Wastewater leaves primary settling with a BOD of $(1 - 0.3)(200\ \text{mg/L}) = 140\ \text{mg/L}$. The efficiency of the activated sludge processing is

$$\eta_{\text{BOD}} = \frac{140\ \frac{\text{mg}}{\text{L}} - 10\ \frac{\text{mg}}{\text{L}}}{140\ \frac{\text{mg}}{\text{L}}} = 0.929\ \ (92.9\%)$$

(b) The aeration tank volume is

$$V_a = Q_o t = \frac{(4 \text{ MGD})\left(10^6 \frac{\text{gal}}{\text{MG}}\right)(6 \text{ hr})}{\left(24 \frac{\text{hr}}{\text{day}}\right)\left(7.48 \frac{\text{gal}}{\text{ft}^3}\right)}$$

$$= 1.34 \times 10^5 \text{ ft}^3$$

(c) The total MLSS can be determined from the food-to-microorganism ratio. Use Eq. 30.4.

$$\text{MLSS} = \frac{S_o Q_o}{(\text{F:M})V_a}$$

$$= \frac{\left(140 \frac{\text{mg}}{\text{L}}\right)(4 \text{ MGD})\left(10^6 \frac{\text{gal}}{\text{MG}}\right)}{\left(0.33 \frac{\text{lbm}}{\text{lbm-day}}\right) \times (1.34 \times 10^5 \text{ ft}^3)\left(7.481 \frac{\text{gal}}{\text{ft}^3}\right)}$$

$$= 1693 \text{ mg/L}$$

(d) The suspended solids content in the recirculated sludge is given by Eq. 30.8.

$$\text{MLSS}_{\text{mg/L}} = \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right)\left(1000 \frac{\text{mL}}{\text{L}}\right)}{\text{SVI}_{\text{mL/g}}}$$

$$= \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right)\left(1000 \frac{\text{mL}}{\text{L}}\right)}{100 \frac{\text{mL}}{\text{g}}}$$

$$= 10{,}000 \text{ mg/L}$$

(e) The recirculation ratio can be calculated from the SVI test. However, the settled volume must first be calculated.

Use Eq. 30.7.

$$V_{\text{settled,mL/L}} = \frac{X_{\text{mg/L}}\text{SVI}_{\text{mL/g}}}{1000 \frac{\text{mg}}{\text{g}}}$$

$$= \frac{\left(1693 \frac{\text{mg}}{\text{L}}\right)\left(100 \frac{\text{mL}}{\text{g}}\right)}{1000 \frac{\text{mg}}{\text{g}}}$$

$$= 169.3 \text{ mL/L}$$

Use Eq. 30.45.

$$R = \frac{V_{\text{settled,mL/L}}}{1000 - V_{\text{settled,mL/L}}}$$

$$= \frac{169.3 \frac{\text{mL}}{\text{L}}}{1000 \frac{\text{mL}}{\text{L}} - 169.3 \frac{\text{mL}}{\text{L}}}$$

$$= 0.204$$

The recirculation is given by Eq. 30.41.

$$Q_r = RQ_o = (0.204)(4 \text{ MGD}) = 0.816 \text{ MGD}$$

(f) The wasted solids are found from the volatile solids wasted. Since 30% of the volatile solids are wasted and the ratio of MLVSS/MLSS is 0.7, the fraction of wasted MLSS is

$$\frac{0.30}{0.7} = 0.429$$

The sludge wasted is

$$(0.429)(4 \text{ MGD})\left(140 \frac{\text{mg}}{\text{L}}\right)\left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)$$

$$= 2005 \text{ lbm/day}$$

(g) The clarifier surface area is

$$A = \frac{Q_t}{\text{v}^*} = \frac{Q_r + Q_o}{\text{v}^*}$$

$$= \frac{(0.81 \text{ MGD} + 4 \text{ MGD})\left(10^6 \frac{\text{gal}}{\text{MG}}\right)}{800 \frac{\text{gal}}{\text{day-ft}^2}}$$

$$= 6010 \text{ ft}^2$$

(h) The fraction of BOD reduction that is attributable to the activated sludge process aeration (exclusive of the wasted sludge) is

$$0.929 - 0.429 = 0.500$$

Since one pound of oxygen is required for each pound of BOD removed, 0.500 pound of oxygen will be required per pound of entering BOD. The required oxygen mass is

$$m_{\text{oxygen}} = (0.500)(4 \text{ MGD})\left(140 \frac{\text{mg}}{\text{L}}\right)\left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)$$

$$= 2337 \text{ lbm/day}$$

The density of air is approximately 0.075 lbm/ft^3, and air is 20.9% oxygen by volume. Considering the efficiency of the oxygenation process, the air required is

$$\dot{V}_{\text{air}} = \frac{2337 \frac{\text{lbm}}{\text{day}}}{(0.209)(0.06)\left(0.075 \frac{\text{lbm}}{\text{ft}^3}\right)}$$

$$= 2.48 \times 10^6 \text{ ft}^3\text{/day}$$

13. OPERATIONAL DIFFICULTIES

Sludge bulking refers to a condition in which the sludge does not settle out. Since the solids do not settle, they leave the sedimentation tank and cause problems in subsequent processes. The sludge volume index can often

(but not always) be used as a measure of settling characteristics. If the SVI is less than 100, the settling process is probably operating satisfactorily. If SVI > 150, the sludge is bulking. Remedies include addition of lime, chlorination, additional aeration, and a reduction in MLSS.

Some sludge may float back to the surface after settling, a condition known as *rising sludge*. Rising sludge occurs when nitrogen gas is produced from denitrification of the nitrates and nitrites. Remedies include increasing the return sludge rate and decreasing the mean cell residence time. Increasing the speed of the sludge scraper mechanism to dislodge nitrogen bubbles may also help.

It is generally held that after 30 min of settling, the sludge should settle to between 20 and 70% of its original volume. If it occupies more than 70%, there are too many solids in the aeration basin, and more sludge should be wasted. If the sludge occupies less than 20%, less sludge should be wasted.

Sludge washout (*solids washout*) can occur during a period of peak flow or even with excess recirculation. Washout is the loss of solids from the sludge blanket in the settling tank. This often happens with insufficient wasting, such that solids build up (to more than 70% in a settling test), hinder settling in the clarifier, and cannot be contained.

14. QUANTITIES OF SLUDGE

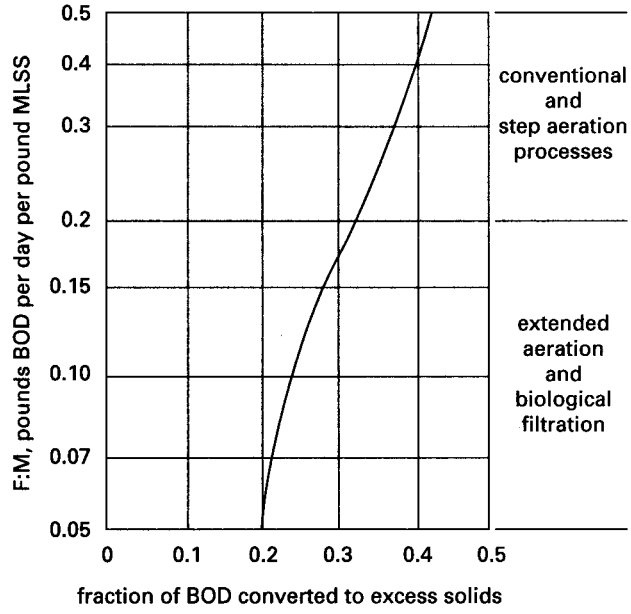
The procedure for determining the volume and mass of sludge from activated sludge processing is essentially the same as for sludge from sedimentation and any other processes. The primary variables, other than mass and volume, are density and/or specific gravity.

$$m_{\text{wet}} = V\rho_{\text{sludge}} = V(\text{SG}_{\text{sludge}})\rho_{\text{water}} \qquad 30.46$$

Raw sludge is approximately 95 to 99% water, and the specific gravity of sludge is only slightly greater than 1.0. The actual specific gravity of sludge can be calculated from the fractional solids content, s, and specific gravity of the sludge solids. (If the sludge specific gravity is known, Eq. 30.47 can be solved for the specific gravity of the solids.) In Eq. 30.47, $1 - s$ is the fraction of the sludge that is water.

$$\begin{aligned}\frac{1}{\text{SG}_{\text{sludge}}} &= \frac{1-s}{1} + \frac{s}{\text{SG}_{\text{solids}}} \\ &= \frac{1 - s_{\text{fixed}} - s_{\text{volatile}}}{1} + \frac{s_{\text{fixed}}}{\text{SG}_{\text{fixed solids}}} \\ &\quad + \frac{s_{\text{volatile}}}{\text{SG}_{\text{volatile solids}}}\end{aligned} \qquad 30.47$$

The volume of sludge can be estimated from its dried mass. Since the sludge specific gravity is approximately 1.0, the sludge volume is



$$V_{\text{sludge,wet}} = \frac{m_{\text{dried}}}{s\rho_{\text{sludge}}} \approx \frac{m_{\text{dried}}}{s\rho_{\text{water}}} \qquad 30.48$$

The dried mass of sludge solids from primary settling basins is easily determined from the decrease in solids. The decrease in suspended solids, ΔSS, due to primary settling is approximately 50% of the total incoming suspended solids.

$$m_{\text{dried}} = (\Delta\text{SS})_{\text{mg/L}} Q_{o,\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \qquad 30.49$$

The dried mass of solids for biological filters and secondary aeration (e.g., activated sludge) can be estimated on a macroscopic basis as a fraction of the change in BOD. In Eq. 30.50, K is the *cell yield*, the fraction of the total influent BOD that ultimately appears as excess biological solids. The cell yield can be estimated from the food-to-microorganism ratio from Fig. 30.6. (Note that the cell yield, K, and yield coefficient, Y, are not the same since K is based on total incoming BOD and Y is based on consumed BOD.)

$$m_{\text{dried}} = KS_{o,\text{mg/L}} Q_{o,\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \qquad 30.50$$

[a] calculated assuming an effluent BOD of approximately 30 mg/L

Figure 30.6 *Approximate Food:Microorganism Ratio Versus Cell Yield*[a]

Table 30.6 *Characteristics of Sludge*

origin of sludge	fraction solids, s	dry mass (lbm/day-person)
primary settling tank	0.06–0.08	0.12
trickling filter	0.04–0.06	0.04
mixed primary settling and trickling filter	0.05	0.16
conventional activated sludge	0.005–0.01	0.07
mixed primary and conventional activated sludge	0.02–0.03	0.19
high-rate activated sludge	0.025–0.05	0.06
mixed primary settling and high-rate activated sludge	0.05	0.18
extended aeration activated sludge	0.02	0.02
filter backwashing water	0.01–0.1	–
softening sludge	0.03–0.15	–

(Multiply lbm/day-person by 0.45 to obtain kg/day·person.)

Example 30.4

A trickling filter plant processes 4 MGD of domestic wastewater with 190 mg/L BOD and 230 mg/L suspended solids. The primary settling tank removes 50% of the suspended solids and 30% of the BOD. The cell yield for the trickling filter is 0.25. What is the total sludge volume from the primary sedimentation tank and trickling filter if the combined solids content of the sludge is 5%?

Solution

The mass of solids removed in primary settling is given by Eq. 30.49.

$$\begin{aligned} m_{\text{dried}} &= (\Delta \text{SS})_{\text{mg/L}} Q_{o,\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \\ &= (0.5)\left(230\ \frac{\text{mg}}{\text{L}}\right)(4\ \text{MGD})\left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \\ &= 3839\ \text{lbm/day} \end{aligned}$$

The mass of solids removed from the trickling filter is calculated from Eq. 30.50.

$$\begin{aligned} m_{\text{dried}} &= K \Delta S_{\text{mg/L}} Q_{o,\text{MGD}} \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \\ &= (0.25)(1-0.3)\left(190\ \frac{\text{mg}}{\text{L}}\right)(4\ \text{MGD}) \\ &\quad \times \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) \\ &= 1110\ \text{lbm/day} \end{aligned}$$

The volume is calculated from Eq. 30.48.

$$\begin{aligned} V &= \frac{m_{\text{dried}}}{s \rho_{\text{water}}} \\ &= \frac{3839\ \frac{\text{lbm}}{\text{day}} + 1110\ \frac{\text{lbm}}{\text{day}}}{(0.05)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)} \\ &= 1586\ \text{ft}^3\text{/day} \end{aligned}$$

15. SLUDGE THICKENING

Waste-activated sludge (WAS) has a typical solids content of 0.5 to 1.0%. *Thickening* of sludge is used to reduce the volume of sludge prior to digestion or dewatering. Thickening is accomplished by decreasing the liquid fraction $(1-s)$, thereby increasing the solids fraction, s. Equation 30.48 shows that the volume of wet sludge is inversely proportional to its solids content.

For dewatering, thickening to at least 4% solids (i.e., 96% moisture) is required; for digestion, thickening to at least 5% solids is required. Depending on the nature of the sludge, polymers may be used with all of the thickening methods. Other chemicals (e.g., lime for stabilization through pH control and potassium permanganate to react with sulfides) can also be used. However, because of cost and increased disposal problems, the trend is toward the use of fewer inorganic chemicals with new thickening or dewatering applications unless special conditions apply.

Gravity thickening occurs in circular sedimentation tanks similar to primary and secondary clarifiers. The settling process is categorized into four zones: the *clarification zone*, containing relatively clear *supernatant*; the *hindered settling zone*, where the solids move downward at essentially a constant rate; the *transition zone*, characterized by a decrease in solids settling rate; and the *compression zone*, where motion is essentially zero.

In *batch gravity thickening*, the tank is filled with thin sludge and allowed to stand. Supernatant is decanted, and the tank is topped off with more thin sludge. The operation is repeated continually or a number of times before the underflow sludge is removed. A heavy-duty (deep-truss) scraper mechanism pushes the settled solids into a hopper in the tank bottom, and the clarified effluent is removed in a peripheral weir. A doubling of solids content is usually possible with gravity thickening. Table 30.7 contains typical characteristics of gravity thickening tanks.

With *dissolved air flotation* (DAF) *thickening* (DAFT), fine air bubbles are released into the sludge as it enters the DAF tank. The solids particles adhere to the air bubbles and float to the surface where they are skimmed away as scum. The scum has a solids content of approximately 4%. Up to 85% of the total solids may be recovered in this manner, and chemical flocculants (e.g., polymers) can increase the recovery to 97 to 99%.

Table 30.7 *Typical Characteristics of Gravity Thickening Tanks*

shape	circular
minimum number of tanks[a]	2
overflow rate	600–800 gal/day-ft^2 (24–33 m^3/day·m^2)
maximum dry solids loading	
primary sludge	22 lbm/day-ft^2 (107 kg/day·m^2)
primary and trickling filter sludge	15 lbm/day-ft^2 (73 kg/day·m^2)
primary and modified aeration activated sludge	12 lbm/day-ft^2 (59 kg/day·m^2)
primary and conventional aeration activated sludge	8 lbm/day-ft^2 (39 mg/day·m^2)
waste-activated sludge	4 lbm/day-ft^2 (20 kg/day·ft^2)
minimum detention time	6 hr
minimum sidewater depth	10 ft (3 m)
minimum freeboard	1.5 ft (0.45 m)

[a]unless alternative methods of thickening are available

With *gravity belt thickening* (GBT), sludge is spread over a drainage belt. Multiple stationary plows in the path of the moving belt may be used to split, turn, and recombine the sludge so that water does not pool on top of the sludge. After thickening, the sludge cake is removed from the belt by a doctor blade.

Gravity thickening is usually best for sludges from primary and secondary settling tanks, while dissolved air flotation and centrifugal thickening are better suited for activated sludge. The current trend is toward using gravity thickening for primary sludge and flotation thickening for activated sludge, then blending the thickened sludge for further processing.

Not all of the solids in sludge are captured in thickening processes. Some sludge solids escape with the liquid portion. Table 30.8 lists typical solids capture fractions.

16. SLUDGE STABILIZATION

Raw sludge is too bulky, odorous, and putrescible to be dewatered easily or disposed of by land spreading. Such sludge can be "stabilized" through chemical addition or by digestion prior to dewatering and landfilling. (Sludge that is incinerated does not need to be stabilized.) Stabilization converts the sludge to a stable, inert form that is essentially free from odors and pathogens.

Sludge can be stabilized chemically by adding lime dust to raise the pH. A rule of thumb is that adding enough lime to raise the pH to 12 for at least 2 hr will inhibit or kill bacteria and pathogens in the sludge. Kiln and cement dust is also used in this manner.

Table 30.8 *Typical Thickening Solids Fraction and Capture Efficiencies*

operation	solids capture range (%)	solids content range (%)
gravity thickeners		
primary sludge only	85–92	4–10
primary and waste-activated	80–90	2–6
flotation thickeners		
with chemicals	90–98	3–6
without chemicals	80–95	3–6
centrifuge thickeners		
with chemicals	90–98	4–8
without chemicals	80–90	3–6
vacuum filtration		
with chemicals	90–98	15–30
belt filter press		
with chemicals	85–98	15–30
filter press		
with chemicals	90–98	20–50
centrifuge dewatering		
with chemicals	85–98	10–35
without chemicals	55–90	10–30

Alternatively, ammonia compounds can be added to the sludge prior to land spreading. This has the additional advantage of producing a sludge with high plant nutrient value.

17. AEROBIC DIGESTION

Aerobic digestion occurs in an open holding tank digester and is preferable with stabilized primary and combined primary-secondary sludges. Up to 70% (typically 40 to 50%) of the volatile solids can be removed in an aerobic digester. Mechanical aerators are used in a manner similar to aerated lagoons. Construction details of aerobic digesters are similar to those of aerated lagoons.

18. ANAEROBIC DIGESTION

Anaerobic digestion occurs in the absence of oxygen. Anaerobic digestion is more complex and more easily upset than aerobic digestion. However, it has a lower operating cost.

Three types of anaerobic bacteria are involved. The first type converts organic compounds into simple fatty or amino acids. The second group of *acid-formed bacteria* converts these compounds into simple organic acids, such as acetic acid. The third group of *acid-splitting bacteria* converts the organic acids to methane, carbon dioxide, and some hydrogen sulfide. The third phase takes the longest time and sets the rate and loadings. The pH should be 6.7 to 7.8, and temperature should be in the mesophilic range of 85 to 100°F (29 to 38°C) for the methane-producing bacteria to be effective. Sufficient alkalinity must be added to buffer acid production.

Table 30.9 *Typical Characteristics of Aerobic Digesters*

minimum number of units	2
size	2–3 ft^3/person (0.05–0.08 m^3/person)
aeration period	
activated sludge only	10–15 days
activated sludge and primary settling sludge	12–18 days
mixture of primary sludge and activated or trickling filter sludge	15–20 days
volatile solids loading	0.1–0.3 lbm/day-ft^3 (1.6–4.8 kg/day·m^3)
volatile solids reduction	40–50%
sludge age	
primary sludge	25–30 days
activated sludge	15–20 days
oxygen required (primary sludge)	1.6–1.9 lbm O_2/lbm BOD removed (1.6–1.9 kg O_2/kg BOD removed)
minimum dissolved oxygen level	1–2 mg/L
mixing energy required by mechanical aerators	0.75–1.5 hp/1000 ft^3 (0.02–0.04 kW/m^3)
maximum depth	15 ft (4.5 m)

A simple single-stage sludge digestion tank consists of an inlet pipe, outlet pipes for removing both the digested sludge and the clear supernatant liquid, a dome, an outlet pipe for collecting and removing the digester gas, and a series of heating coils for circulating hot water.

In a single-stage, floating-cover digester, sludge is brought into the tank at the top. The contents of the digester stratify into four layers: scum on top, clear supernatant, a layer of actively digesting sludge, and a bottom layer of concentrated sludge. Some of the contents may be withdrawn, heated, and returned in order to maintain a proper digestion temperature.

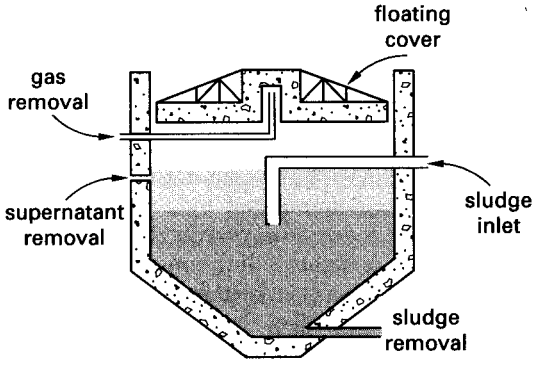

Figure 30.7 *Simple Anaerobic Digester*

Supernatant is removed along the periphery of the digester and returned to the input of the processing plant. Digested sludge is removed from the bottom and dewatered prior to disposal. Digester gas is removed from the gas dome. Heat from burning the methane can be used to warm the sludge that is withdrawn or to warm raw sludge prior to entry.

A reasonable loading and well-mixed digester can produce a well-stabilized sludge in 15 days. With poorer mixing, 30 to 60 days may be required.

A single-stage digester performs the functions of digestion, gravity thickening, and storage in one tank. In a two-stage process, two digesters in series are used. Heating and mechanical mixing occur in the first digester. Since the sludge is continually mixed, it will not settle. Settling and further digestion occur in the unheated second tank.

Germany began experimenting with large spherical and egg-shaped digesters in the 1950s. These and similar designs are experiencing popularity in the United States. Volumes are on the order of 100,000 to 400,000 ft^3 (3000 to 12,000 m^3), and digesters can be constructed from either prestressed concrete or steel. Compared with conventional cylindrical digesters, the egg-shaped units minimize problems associated with the accumulation of solids in the lower corners and collection of foam and scum on the upper surfaces. The shape also promotes better mixing that enhances digestion. However, variations in the shape greatly affect grit collection and required mixing power. Mixing can be accomplished with uncombined gas mixing, mechanical mixing using an impeller and draft-tube, and pumped recirculation. Typical volatile suspended solids loading rates are 0.062 to 0.17 lbm VSS/ft^3-day (1 to 2.8 kg VSS/m^3·day) with a 15 to 25 day retention time. Operational problems include grit accumulation, gas leakage, and foaming.

19. METHANE PRODUCTION

The theoretical volume of methane produced from sludge digestion is 5.61 ft^3 (0.35 m^3) per pound (per kilogram) of BOD converted. Wasted sludge does not contribute to methane production, and the theoretical amount is reduced by various inefficiencies. Therefore, the actual volume of methane produced is predicted by Eq. 30.51. The total volume of digester gas is larger than the methane volume alone since methane constitutes about ⅔ of the total volume. E is the efficiency of waste utilization, typically 0.6 to 0.9. S_o is the ultimate BOD of the influent.

$$V_{\text{methane,m}^3\text{/day}} = \left(0.35\ \frac{\text{m}^3}{\text{kg}}\right) \times \left(\frac{EQ_{\text{m}^3\text{/day}} S_{o,\text{mg/L}}}{1000\ \frac{\text{g}}{\text{kg}}} - 1.42 P_{x,\text{kg/day}}\right) \quad \text{[SI]} \quad \textit{30.51(a)}$$

$$V_{\text{methane,ft}^3\text{/day}} = \left(5.61\ \frac{\text{ft}^3}{\text{lbm}}\right) \times \left((EQ_{\text{MGD}} S_{o,\text{mg/L}}) \left(8.345\ \frac{\text{lbm-L}}{\text{MG-mg}}\right) - 1.42 P_{x,\text{lbm/day}}\right) \quad \text{[U.S.]} \quad \textit{30.51(b)}$$

Table 30.10 *Typical Characteristics of Single-Stage Heated Anaerobic Digester*

minimum number of units	2
size	
trickling filter sludge	3–4 ft^3/person (0.08–0.11 m^3/person)
primary and secondary sludge	6 ft^3 (0.16 m^3/person)
volatile solids loading	0.13–0.2 lbm/day-ft^3 (2.2–3.3 kg/day·m^3)
temperature	85–100°F; 95–98°F optimum (29–38°C; 35–36.7°C optimum)
pH	6.7–7.8; 6.9–7.2 optimum
gas production	7–10 ft^3/lbm volatile solids (0.42–0.60 m^3/kg volatile solids)
	0.5–1.0 ft^3/day-person (0.014–0.027 m^3/day·person)
gas composition	65% methane; 35% carbon dioxide
gas heating value	500–700; 600 Btu/ft^3 typical (19–26 MJ/m^3; 22 MJ/m^3)
sludge final moisture content	90–95%
sludge detention time	30–90 days (conventional) 15–25 days (high rate)
depth	20–45 ft (6–14 m)
minimum freeboard	2 ft (0.6 m)

The heating value of digester gas listed in Table 30.10 is approximately 600 Btu/ft^3 (22 MJ/m^3). This value is appropriate for digester gas with the composition given: 65% methane and 35% carbon dioxide by volume. Carbon dioxide is not combustible and does not contribute to the heating effect. The actual heating value will depend on the volumetric fraction of methane. The temperature and pressure also affect the gas volume. At 60°F (15.6°C) and 1 atm, the pure methane has a lower heating value of 913 Btu/ft^3 (34.0 MJ/m^3). The higher heating value of 1013 Btu/ft^3 (37.7 MJ/m^3) should not normally be used, since the water vapor produced during combustion is not allowed to settle out.

The total heating energy is

$$q = (\text{LHV})V_{\text{fuel}} \qquad 30.52$$

20. HEAT TRANSFER AND LOSS

In an adiabatic reactor, energy is required only to heat the influent sludge to the reactor temperature. In a nonadiabatic reactor, energy will also be required to replace energy lost to the environment through heat transfer from the exposed surfaces.

The energy required to increase the temperature of sludge from T_1 to T_2 is given by Eq. 30.53. The specific heat, c_p, of sludge is assumed to be the same as for water, 1.0 Btu/lbm-°F (4190 J/kg·°C).

$$\begin{aligned} q &= m_{\text{sludge}}c_p(T_2 - T_1) \\ &= V_{\text{sludge}}\rho_{\text{sludge}}c_p(T_2 - T_1) \end{aligned} \qquad 30.53$$

The energy lost from a heated digester can be calculated in several ways. If the surface temperature is known, the convective heat lost from a heated surface to the surrounding air depends on the convective outside *film coefficient*, h. The film coefficient depends on the surface temperature, air temperature, orientation, and prevailing wind. Heat losses from digester sides, top, and other surfaces must be calculated separately and combined.

$$q = hA_{\text{surface}}(T_{\text{surface}} - T_{\text{air}}) \qquad 30.54$$

If the temperature of the digester contents is known, it can be used with the *overall coefficient of heat transfer*, U (a combination of inside and outside film coefficients), as well as the conductive resistance of the digester walls to calculate the heat loss.

$$q = UA_{\text{surface}}(T_{\text{contents}} - T_{\text{air}}) \qquad 30.55$$

If the temperatures of the inner and outer surfaces of the digester walls are known, the energy loss can be calculated as a conductive loss. k is the average thermal conductivity of the digester wall, and L is the wall thickness.

$$q = \frac{kA(T_{\text{inner}} - T_{\text{outer}})}{L} \qquad 30.56$$

21. SLUDGE DEWATERING

Once sludge has been thickened, it can be digested or dewatered prior to disposal. At water contents of 75%, sludge can be handled with shovel and spade, and is known as *sludge cake*. A 50% moisture content represents the general lower limit for conventional drying methods. Several methods of dewatering are available, including vacuum filtration, pressure filtration, centrifugation, sand and gravel drying beds, and lagooning.

Generally, vacuum filtration and centrifugation are used with undigested sludge. A common form of vacuum filtration occurs in a *vacuum drum filter*. A hollow drum covered with filter cloth is partially immersed in a vat of sludge. The drum turns at about 1 rpm. Suction is applied from within the drum to attract sludge to the filter surface and to extract moisture. The sludge cake is dewatered to about 75 to 80% moisture content (solids content of 20 to 25%) and is then scraped off the belt by a blade or delaminated by a sharp bend in the belt material. This degree of dewatering is sufficient for sanitary landfill. A higher solids content of 30 to 33% is needed, however, for direct incineration unless external fuel is provided. Chemical flocculants (e.g., polymers or ferric chloride, with or without lime) may be used to collect finer particles on the filter drum. Performance is measured in terms of the amount of dry solids removed per unit area (kg/m^2·hr). Typical performance is 3.5 lbm/hr-ft^2 (17 kg/hr·m^2).

Belt filter presses accept a continuous feed of conditioned sludge and use a combination of gravity drainage

and mechanically applied pressure. Sludge is applied to a continuous-loop woven belt (cotton, wool, nylon, polyester, woven stainless steel, etc.) where the sludge begins to drain by gravity. As the belt continues on, the sludge is compressed under the action of one or more rollers. Belt presses typically have belt widths of 80 to 140 in (2.0 to 3.5 m) and are loaded at the rate of 60 to 450 lbm/ft-hr (90 to 680 kg/m·h). Moisture content of the cake is typically 70 to 80%.

Pressure filtration is usually chosen only for sludges with poor dewaterability (such as waste-activated sludge) and where it is desired to dewater to a solids content higher than 30%. *Recessed plate filter presses* operate by forcing sludge at pressures of up to 120 psi (830 kPa) into cavities of porous filter cloth. The filtrate passes through the cloth, leaving the filter cake behind. When the filter becomes filled with cake, it is taken offline and opened. The filter cake is either manually or automatically removed.

Filter press sizing is based on a continuity of mass. In Eq. 30.57, s is the solids content as a decimal fraction in the filter cake.

$$\begin{aligned} V_{\text{press}}\rho_{\text{filter cake}}s_{\text{filter cake}} &= V_{\text{sludge,per cycle}}s_{\text{sludge}}\rho_{\text{sludge}} \\ &= V_{\text{sludge,per cycle}}s_{\text{sludge}}\rho_{\text{water}}\text{SG}_{\text{sludge}} \end{aligned} \quad \textit{30.57}$$

Centrifuges can operate continuously and reduce water content to about 70%, but the effluent has a high percentage of suspended solids. The types of centrifuges used include solid bowl (both cocurrent and countercurrent varieties) and imperforate basket decanter centrifuges. With *solid bowl centrifuges*, sludge is continuously fed into a rotating bowl where it is separated into a dilute stream (the *centrate*) and a dense cake consisting of approximately 70 to 80% water. Since the centrate contains fine, low-density solids, it is returned to the wastewater treatment system. Equation 30.58 gives the number of gravities acting on a rotating particle. Rotational speed is typically 1500 to 2000 rpm. A polymer may be added to increase the capture efficiency (same as reducing the solids content of the centrate) and, accordingly, increase the feed rate.

$$G = \frac{\omega^2 r}{g} \quad \textit{30.58}$$

Sand drying beds are preferable when digested sludge is to be disposed of in a landfill since sand beds produce sludge cake with a low moisture content. Drying beds are enclosed by low concrete walls. A broken stone/gravel base 8 to 20 in (20 to 50 cm) thick is covered by 4 to 8 in (10 to 20 cm) of sand. Drying occurs primarily through drainage, not evaporation. Water that seeps through the sand is removed by a system of drainage pipes. Typically, sludge is added to a depth of about 8 to 12 in (20 to 30 cm) and allowed to dry for 10 to 30 days.

There is no theory-based design method, and drying beds are sized by rules of thumb. The drying area required is approximately 1 to 1.5 ft^2 (0.09 to 1.4 m^2) per person for primary digested sludge, 1.25 to 1.75 ft^2 (0.11 to 0.16 m^2) per person for primary and trickling filter digested sludge, 1.75 to 2.5 ft^2 (0.16 to 0.23 m^2) per person for primary and waste-activated digested sludge, and 2 to 2.5 ft^2 (0.18 to 0.23 m^2) per person for primary and chemically precipitated digested sludge. This area can be reduced by approximately 50% if transparent covers are placed over the beds, creating a "greenhouse effect" and preventing the spread of odors.

Other types of drying beds include paved beds (both drainage and decanting types), vacuum-assisted beds, and artificial media (e.g., stainless steel wire and high-density polyurethane panels) beds.

Sludge dewatering by freezing and thawing in exposed beds is effective during some months in parts of the country.

Example 30.5

A belt filter press handles an average flow of 19,000 gal/day of thickened sludge containing 2.5% solids by weight. Operation is 8 hr/day and 5 days/wk. The belt filter press loading is specified as 500 lbm/m-hr (lbm/hr per meter of belt width). The dewatered sludge is to have 25% solids by weight; the suspended solids concentration in the filtrate is 900 mg/L. The belt is continuously washed on its return path at the rate of 24 gal/m-min. The specific gravities of the sludge feed, dewatered cake, and filtrate are 1.02, 1.07, and 1.01 respectively. (a) What size belt is required? (b) What is the volume of filtrate rejected? (c) What is the solids capture fraction?

Solution

(a) The daily masses of wet and dry influent sludge are

$$\begin{aligned} m_{\text{wet}} &= V\rho_{\text{sludge}} = V\rho_{\text{water}}\text{SG}_{\text{sludge}} \\ &= \left(19{,}000\ \frac{\text{gal}}{\text{day}}\right)\left(\frac{\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)(1.02)}{7.48\ \frac{\text{gal}}{\text{ft}^3}}\right) \\ &= 1.617 \times 10^5\ \text{lbm/day} \end{aligned}$$

$$\begin{aligned} m_{\text{dry}} &= (\text{fraction solids})m_{\text{wet}} \\ &= (0.025)\left(1.617 \times 10^5\ \frac{\text{lbm}}{\text{day}}\right) \\ &= 4042\ \text{lbm/day} \end{aligned}$$

Since the influent is received continuously but the belt filter press operates only 5 days a week for 8 hours per day, the average hourly processing rate is

$$\frac{\left(4042\ \frac{\text{lbm}}{\text{day}}\right)\left(\frac{7\ \text{days}}{5\ \text{days}}\right)}{8\ \frac{\text{hr}}{\text{day}}} = 707\ \text{lbm/hr}$$

The belt size required is

$$w = \frac{707\ \frac{\text{lbm}}{\text{hr}}}{500\ \frac{\text{lbm}}{\text{m-hr}}} = 1.41\ \text{m}$$

Use one 1.5 m belt filter press. A second standby unit may also be specified.

(b) The mass of solids received each day is

$$\left(707\ \frac{\text{lbm}}{\text{hr}}\right)\left(8\ \frac{\text{hr}}{\text{day}}\right) = 5656\ \text{lbm/day}$$

The fractional solids in the filtrate is

$$s_{\text{filtrate}} = \frac{900\ \frac{\text{mg}}{\text{L}}}{\left(1000\ \frac{\text{mg}}{\text{g}}\right)\left(1000\ \frac{\text{g}}{\text{L}}\right)} = 0.0009$$

The solids balance is

$$\text{influent solids} = \text{sludge cake solids} + \text{filtrate solids}$$

$$5656\ \frac{\text{lbm}}{\text{day}} = \left(\frac{Q_{\text{cake,gal/day}}}{7.48\ \frac{\text{gal}}{\text{ft}^3}}\right)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right) \times (1.07)(0.25) + \left(\frac{Q_{\text{filtrate,gal/day}}}{7.48\ \frac{\text{gal}}{\text{ft}^3}}\right)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right) \times (1.01)(0.0009)$$

The total liquid flow rate is the sum of the sludge flow rate and the washwater flow rate.

$$\begin{aligned} Q_{\text{total}} &= Q_{\text{cake}} + Q_{\text{filtrate}} \\ &= \left(19{,}000\ \frac{\text{gal}}{\text{day}}\right)\left(\frac{7\ \text{days}}{5\ \text{days}}\right) + \left(24\ \frac{\text{gal}}{\text{m-min}}\right)(1.5\ \text{m})\left(60\ \frac{\text{min}}{\text{hr}}\right)\left(8\ \frac{\text{hr}}{\text{day}}\right) \\ &= 43{,}880\ \text{gal/day} \end{aligned}$$

Solving simultaneously,

$$Q_{\text{cake}} = 2396\ \text{gal/day}$$

$$Q_{\text{filtrate}} = 41{,}484\ \text{gal/day}$$

(c) The solids in the filtrate are

$$m_{\text{filtrate}} = \left(\frac{41{,}484\ \frac{\text{gal}}{\text{day}}}{7.48\ \frac{\text{gal}}{\text{ft}^3}}\right) \times \left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)(1.01)(0.0009) = 315\ \text{lbm/day}$$

The solids capture fraction is

$$\frac{\text{influent solids} - \text{filtrate solids}}{\text{influent solids}} = \frac{5656\ \frac{\text{lbm}}{\text{day}} - 315\ \frac{\text{lbm}}{\text{day}}}{5656\ \frac{\text{lbm}}{\text{day}}} = 0.944$$

22. SLUDGE DISPOSAL

Liquid sludge and sludge cake disposal options are limited to landfills; incineration; nonagricultural land application such as strip-mine reclamation; agricultural land application; commercial applications (known as *distribution and marketing* and *beneficial reuse*) such as composting, special monofills, and surface impoundments; and various state-of-the-art methods. Different environmental contaminants are monitored with each disposal method, making the options difficult to evaluate.

If a satisfactory site is available, sludge, sludge cake, screenings, and scum can be discarded in municipal *landfills*. Approximately 40% of the sludge produced in the United States is disposed of in this manner. This has traditionally been the cheapest disposal method, even when transportation costs are included.

The sludge composition and its potential effects on landfill leachate quality must be considered. Sludge with minute concentrations of monitored substances (e.g., heavy metals such as cadmium, chromium, copper, lead, nickel, and zinc) may be classified as hazardous waste, requiring disposal in hazardous waste landfills.

Sludge-only *monofills* and other surface impoundments may be selected in place of municipal landfills. Monofills are typically open pits protected by liners, slurry cutoff walls, and levees (as protection against floods). Monofills may include a pug mill to combine sludge with soil from the site.

Approximately 25% of the sludge produced in the United States is disposed of in a *beneficial reuse program* such as surface spreading and/or composting. Isolated cropland, pasture, and forest land (i.e., "silvaculture") is perfect for surface spreading. However, sludge applied to the surface may need to be harrowed into the soil soon after spreading to prevent water pollution from sludge runoff and possible exposure to or spread of bacteria. Alternatively, the sludge can be injected 12 to 18 in (300 to 460 mm) below grade directly from distribution equipment.

By itself, filter cake is not highly useful as a fertilizer since its nutrient content is low. However, it is a good filler and soil conditioner for more nutrient-rich fertilizers. Other than as filler, filter cake has few practical applications.

Where sludges have low metals contents, *composting* (in static piles or vessels) can be used. *Compost* is a dry, odor-free soil conditioner with applications in turf grass, landscaping, land reclamation, and other horticultural industries. These markets can help to defray the costs of the program. Control of odors, cold weather operations, and concern about airborne pathogens are problems with *static pile composting.* Expensive air-quality scrubbers add to the cost of processing. With *in-vessel composting*, dewatered raw sludge is mixed with a bulking material, placed in an enclosed tank, and mixed with air in the tank.

Incineration is the most expensive treatment, though it results in almost total destruction of volatile solids, is odor free, and is independent of the weather. Approximately 20% of sludge is disposed of in this manner. A solids content of 30 to 33% is needed for direct incineration without the need to provide external fuel (i.e., so that the sludge burns itself). Air quality controls, equipment, and the regulatory permitting needed to meet strict standards may make incineration prohibitively expensive in some areas. The incineration ash produced represents a disposal problem of its own.

State-of-the-art options include using sludge solids in bricks, tiles, and other building materials; below-grade injection; subsurface injection wells; multiple-effect (Carver-Greenfield) evaporation; combined incineration with solid waste in "mass burn" units; and fluidized-bed gasification. The first significant installation attempting to use sludge solids as powdered fuel for power generation was the 25 MW Hyperion Energy Recovery System at the Hyperion treatment plant in Los Angeles. This combined-cycle cogeneration plant unsuccessfully attempted to operate using the Carver-Greenfield process and a fluidized-bed gasifier to convert sludge solids to fuel.

Ocean dumping, once a popular option for coastal areas, has been regulated out of existence and is no longer an option for new or existing facilities.

PRACTICE PROBLEMS

Sludge Quantities

1. 33 m^3/day of thickened sludge with a suspended solids content of 3.8% and 13 m^3/day of anaerobic digester sludge with a suspended solids content of 7.8 are produced in a wastewater treatment plant.

(a) What would be the effect of using a filter press to increase the solids content of the thickened sludge to 24%?

(A) 4000 m^3/yr
(B) 8000 m^3/yr
(C) 10,000 m^3/yr
(D) 15,000 m^3/yr

The answer is (C).

(b) What volume of digester sludge must be disposed of from sand drying beds that increase the solids concentration to 35%?

(A) 500 m^3/yr
(B) 1000 m^3/yr
(C) 2000 m^3/yr
(D) 4000 m^3/yr

The answer is (B).

2. An activated sludge plant processes 10 MGD of wastewater with 240 mg/L BOD and 225 mg/L suspended solids. 70% of the suspended solids are inorganic. The discharge from the final clarifier contains 15 mg/L BOD (all organic) and 20 mg/L suspended solids (all inorganic). Primary clarification removes 60% of the suspended solids and 35% of the BOD. The BOD reduction in the primary clarifier does not contribute to sludge production. The sludge produced has a specific gravity of 1.02 and a solids content of 6%. The cell yield (conversion of BOD to biological solids) is 60%. The final clarifier does not reduce BOD.

(a) What is the daily mass of dry sludge solids produced?

(A) 2500 lbm/day
(B) 5000 lbm/day
(C) 10,000 lbm/day
(D) 20,000 lbm/day

The answer is (D).

(b) Assuming that the sludge is completely dried and compressed solid, what is the daily sludge volume?

(A) 200 ft^3/day
(B) 500 ft^3/day
(C) 1000 ft^3/day
(D) 1600 ft^3/day

The answer is (A).

(c) Assuming that the final moisture content in the sludge is 70% and air voids increase the volume by 10%, what is the daily sludge volume?

(A) 200 ft^3/day
(B) 500 ft^3/day
(C) 1000 ft^3/day
(D) 1600 ft^3/day

The answer is (C).

1. MUNICIPAL SOLID WASTE

Municipal solid waste (MSW, known for many years as "*garbage*") consists of the solid material discarded by a community, including excess food, containers and packaging, residential garden wastes, other household discards, and light industrial debris. Hazardous wastes, including paints, insecticides, lead car batteries, used crankcase oil, dead animals, raw animal wastes, and radioactive substances present special disposal problems and are not included in MSW.

MSW is generated at the average rate of approximately 5 to 8 lbm/capita-day (2.3 to 3.6 kg/capita·day). Five lbm/capita-day (2.3 kg/capita·day) is a conservative estimate commonly used in design studies.

Although each community's MSW has its own characteristics, Table 31.1 gives average composition in the United States. The moisture content of MSW is approximately 20%.

Table 31.1 *Typical Characteristics of MSW*[a,b]

component	percentage by weight
paper, cardboard	35.6
yard waste	20.1
food waste	8.9
metal	8.9
glass	8.4
plastics	7.3
wood	4.1
rubber, leather	2.8
cloth	2.0
other (ceramic, stone, dirt)	1.9

2. LANDFILLS

Municipal solid waste has traditionally been disposed of in *municipal solid waste landfills* (MSWLs, for many years referred to as "*dumps*"). Other wastes, including incineration ash and water treatment sludge, may be included with MSW in some landfills.

The fees charged to deposit waste are known as *tipping fees.* Tipping fees are generally higher in the eastern United States (where landfill sites are becoming scarcer). Tipping fees for resource recovery plants are approximately double those of traditional landfills.

Many early landfills were not designed with liners, not even simple compacted-soil bottom layers. Design was often by rules of thumb, such as the bottom of the landfill had to be at least 5 ft (1.5 m) above maximum elevation of groundwater and 5 ft (1.5 m) above bedrock. Percolation through the soil was believed sufficient to make the leachate bacteriologically safe. However, inorganic pollutants can be conveyed great distances, and the underlying soil itself can no longer be used as a barrier to pollution and to perform filtering and cleansing functions.

Landfills without bottom liners are known as *natural attenuation* (NA) *landfills*, since the native soil is used to reduce the concentration of leachate components. Landfills lined with clay (pure or bentonite-amended soil) or synthetic liners are known as *containment landfills.*

Landfills can be incrementally filled in a number of ways. With the *area method*, solid waste is spread and compacted on flat ground before being covered. With the *trench method*, solid waste is placed in a trench and covered with the trench soil. In the *progressive method* (also known as the *slope/ramp method*), cover soil is taken from the front (toe) of the working face.

Landvaults are essentially above-ground piles of MSW placed on flat terrain. This design, with appropriate covers, liners, and instrumentation, has been successfully used with a variety of industrial wastes, including incineration ash and wastewater sludge. However, except when piggybacking a new landfill on top of a closed landfill, it is not widely used with MSW.

Waste is placed in layers, typically 2 to 3 ft thick (0.6 to 0.9 m), and is compacted before soil is added as a cover. Two to five passes by a tracked bulldozer are sufficient to compact the MSW to 800 to 1500 lbm/yd^3 (470 to 890 kg/m^3). (A density of 1000 lbm/ft^3 or 590 kg/m^3 is used in design studies.) The *lift* is the height of the covered layer, as shown in Fig. 31.2. When the landfill layer has reached full height, the ratio of solid waste volume to soil cover volume will be approximately between 4:1 and 3:1.

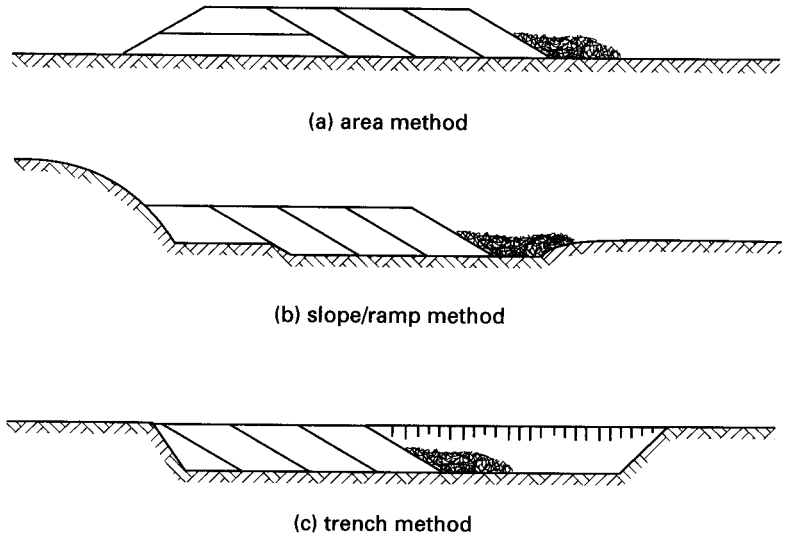

Figure 31.1 *Landfill Creation Methods*

The *cell height* is typically taken as 8 ft (2.4 m) for design studies, although it can actually be much higher. The height should be chosen to minimize the cover material requirement consistent with the regulatory requirements. Cell slopes will be less than 40°, and typically 20° to 30°.

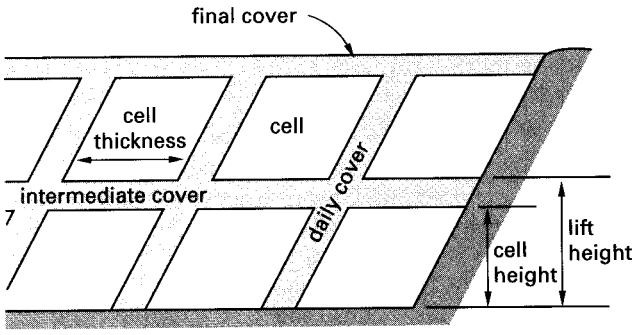

Figure 31.2 *Landfill Cells*

Each *cell* is covered by a soil layer 0.5 to 1.0 ft (0.15 to 0.3 m) in thickness. The final top and side covers should be at least 2 ft (0.6 m) thick. Daily, intermediate, and final soil covers are essential to proper landfill operation. The daily and intermediate covers prevent fly emergence, discourage rodents, reduce odors, and reduce wind-blown litter. In the event of ignition, the soil layers form fire stops within the landfill.

The final soil cover (cap) is intended to reduce or eliminate entering moisture. The soil cover also contains and channels landfill gas and provides a pleasing appearance and location for growing vegetation.

3. LANDFILL CAPACITY

The *compaction factor*, CF, is a multiplicative factor used to calculate the compacted volume for a particular type of waste and compaction method. The compacted volume of MSW or components within the waste is

$$V_c = (\mathrm{CF})V_o \qquad 31.1$$

The daily increase in landfill volume is predicted by Eq. 31.2. N is the population size, G is the per-capita MSW generation rate, and γ is the landfill overall specific weight calculated as a weighted average of soil and compacted MSW specific weights. Soils have specific weights between 70 and 130 lbf/ft^3 (densities between 1100 and 2100 kg/m^3). A value of 100 lbf/ft^3 (1600 kg/m^3) is commonly used in design studies.

$$\Delta V_{\mathrm{day}} = \frac{NG(\mathrm{LF})}{\gamma} = \frac{NG(\mathrm{LF})}{\rho g} \qquad \text{[SI]} \qquad 31.2(a)$$

$$\Delta V_{\mathrm{day}} = \frac{NG(\mathrm{LF})}{\gamma} = \frac{NG(\mathrm{LF})g_c}{\rho g} \qquad \text{[U.S.]} \qquad 31.2(b)$$

The *loading factor*, LF, is 1.25 for a 4:1 volumetric ratio and is calculated from Eq. 31.3 for other ratios.

$$\mathrm{LF} = \frac{V_{\mathrm{MSW}} + V_{\mathrm{cover\ soil}}}{V_{\mathrm{MSW}}} \qquad 31.3$$

Most large-scale sanitary landfills do not apply daily cover to deposited waste. Time, cost, and reduced capacity are typically cited as the reasons that the landfill is not covered with soil. In the absence of such cover, the loading factor has a value of 1.0.

4. SUBTITLE D LANDFILLS

Since 1992, new and expanded municipal landfills in the United States must satisfy strict design regulations and are designated "*Subtitle D landfills*," referring to Subtitle D of the Resource Conservation and Recovery Act (RCRA). The regulations apply to any landfill designed to hold municipal solid waste, biosolids, and ash from MSW incineration.

Construction of landfills is prohibited near sensitive areas such as airports, floodplains, wetlands, earthquake zones, and geologically unstable terrain. Air quality control methods are required to control emission of dust, odors (from hydrogen sulfide and volatile organic vapors), and landfill gas. Runoff from storms must be controlled.

Subtitle D landfills must have *double-liner systems*, defined as "two or more liners and a leachate collection system above and between such liners." While states can specify greater protection, the minimum (basic) bottom layer requirements are a 30-mil flexible PVC membrane liner (FML) and at least 2 ft of compacted soil with a maximum hydraulic conductivity of 1.2×10^{-5} ft/hr (1×10^{-7} cm/s). If the membrane is high-density polyethylene (HDPE), the minimum thickness is 60 mils. 30-mil PVC costs less than 60-mil HDPE, but the 60-mil product offers superior protection.

The preferred double liner consists of two FMLs separated by a drainage layer (approximately 0.5 m thick) of sand, gravel, or *drainage netting* and placed on low-permeability soil. This is the standard design for *Subtitle C* hazardous waste landfills. The advantage of selecting the preferred design for municipal landfills is realized in the permitting process.

The minimum thickness is 20 mils for the top FML, and the maximum hydraulic conductivity of the cover soil is 1.8×10^{-5} ft/hr (1.5×10^{-7} cm/s).

A series of wells and other instrumentation are required to detect high hydraulic heads and the accumulation of heavy metals and volatile organic compounds (VOCs) in the leachate.

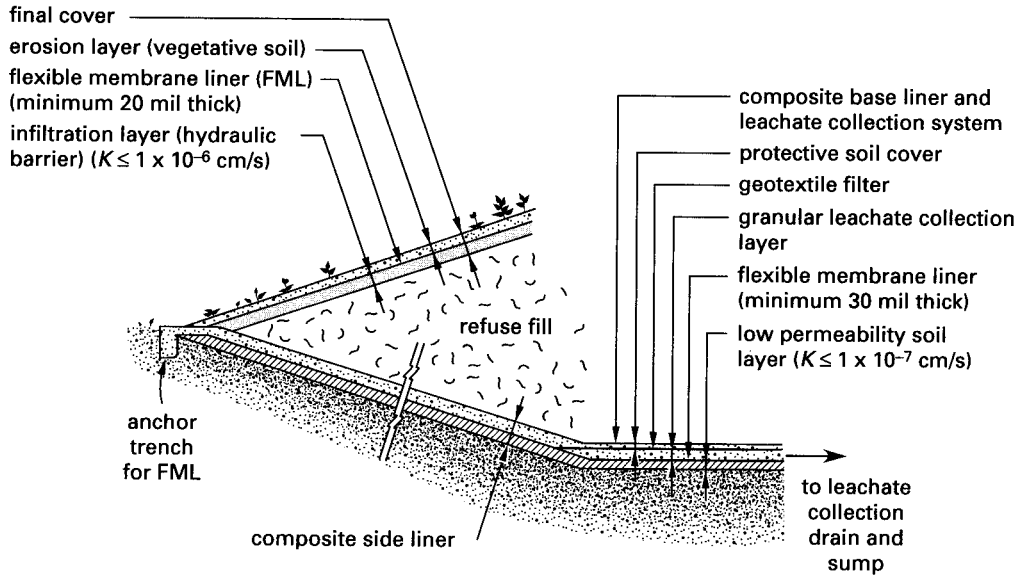

Figure 31.3 *Subtitle D Liner and Cover Detail*

5. CLAY LINERS

Liners constructed of well-compacted bentonite clays fail by fissuring (as during freeze-thaw cycles), dessication (i.e., drying out), chemical interaction, and general disruption. Permeability increases dramatically with organic fluids (hydrocarbons) and acidic or caustic leachates. Clays need to be saturated and swollen to retain their high impermeabilities. Permeabilities measured in the lab as 1.2×10^{-5} ft/hr (10^{-7} cm/s) can actually be 1.2×10^{-3} ft/hr (10^{-5} cm/s) in the field.

Although a 0.5 to 1.0 ft (0.15 to 0.30 m) thickness could theoretically contain the leachate, the probability of success is not high when typical exposure issues are considered. Clay liners with thicknesses of 4 to 5 ft (1.2 to 1.5 m) will still provide adequate protection, even when the top half has degraded.

6. FLEXIBLE MEMBRANE LINERS

Synthetic *flexible membrane liners* (FMLs, the term used by the United States EPA), also known as *synthetic membranes, synthetic membrane liners* (SMLs), *geosynthetics, geomembranes*, and liners are highly attractive because of their negligible permeabilities, and good chemical resistance. The term *geocomposite liner* is used when referring to a combination of FML and one or more compacted clay layers.

FML materials include polyvinyl chloride (PVC); chlorinated polyethylene (CPE); low-density polyethylene (LDPE); linear, low-density polyethylene (LLDPE); very low density polyethylene (VLDPE); high-density polyethylene (HDPE); chlorosulfonated polyethylene, also known as Hypalon® (CSM or CSPE); ethylene propylene dienemonomer (EP or EPDM); polychloroprene, also known as neoprene (CR); isobutylene isoprene, also known as butyl (IIR); and oil resistant polyvinyl chloride (ORPVC). LDPE covers polyethylene with densities in the range of about 0.900 to 0.935 g/cm^3, while HDPE covers the range from 0.935 to 0.970 g/cm^3.

Currently, HDPE is preferred for municipal landfills and hazardous waste sites because of its high tensile strength, high toughness (resistance to tear and puncture), and ease of seaming. HDPE has captured the majority of the FML market.

Some FMLs can be manufactured with an internal nylon or dacron mesh, known as a *scrim*, or a spread coating on one side. The resulting membrane is referred to as a *reinforced* or *supported membrane*. An "R" is added to the name to indicate the reinforcement (e.g., "HDPE-R"). Membranes without internal scrims are *unreinforced* or *unsupported membranes*.

FMLs can be embossed or textured to increase the friction between the FML and any soil layer adjacent to it.

FMLs are sealed to the original grade and restrained against movement by deep *anchor trenches* around the periphery of the landfill.

FMLs fail primarily by puncturing, tearing, and long-term exposure to ultraviolet (UV) rays. Freezing temperatures may also weaken them. FMLs are protected from UV radiation by a soil backfill with a minimum thickness of approximately 6 in (15 cm). The cover soil should be placed promptly.

7. LANDFILL CAPS

The landfill *cap* (*top cap*) is the *final cover* placed over the landfill. Under Subtitle D regulations, caps cannot be any more permeable than the bottom liners. Therefore, only preexisting landfills can be capped with clay.

Caps fail by desiccation, penetration by roots, rodent and other animal activity, freezing and thawing cycles, erosion, settling, and breakdown of synthetic liners from sunlight exposure. Failure can also occur when the cover collapses into the disposal site due to voids opening below or excess loading (rainwater ponding) above.

Synthetic FML caps offer several advantages over clay caps—primarily lower permeability, better gas containment, faster installation, and easier testing and inspection.

Preferred landfill design incorporates maximum slopes of 1:1 or 1:1.5 (horizontal:vertical), with horizontal tiers (benches) every so often. However, many landfills have slopes as steep as 1:3 (horizontal:vertical). This is steep enough to cause concern about cap slope instability. Although clay caps can be constructed this steep, synthetic membranes have lower *interfacial friction angles* and are too smooth for use on steep slopes. Slippage between different layers in the cap (e.g., between the FML and the soil cover) is known as *veneer failure.* Some relief is possible with *textured synthetics.*

A common cap system is a textured synthetic with a nonwoven geotextile. Vertical cap collapse can be prevented by incorporating a high-strength plastic *geogrid.*

Table 31.2 *Typical Interfacial Friction Angles*

interface	typical friction angle
nonwoven geotextile/smooth FML	10°–13°
compacted sand/smooth FML	15°–25°
compacted clay/smooth FML	5°–20°
nonwoven geotextile/textured FML	25°–35°
compacted sand/textured FML	20°–35°
compacted clay/textured FML	15°–32°

8. LANDFILL SITING

Sanitary landfills should be designed for a 5 yr minimum life. Sanitary landfill sites are selected on the basis of many relevant factors, including (a) economics and the availability of inexpensive land; (b) location, including ease of access, transport distance, acceptance by the population, and aesthetics; (c) availability of cover soil, if required; (d) wind direction and speed, including odor, dust, and erosion considerations; (e) flat topography; (f) dry climate and low infiltration rates; (g) location (elevation) of the water table; (h) low risk of aquifer contamination; (i) types and permeabilities of underlying strata; (j) avoidance of winter freezing; (k) future growth and capacity requirements; and (l) ultimate use.

Suitable landfill sites are becoming difficult to find, and once identified, they are subjected to a rigorous permitting process. They are also objected to by residents near the site and MSW transport corridor. This is referred to as the *NIMBY syndrome* (not in my backyard). People agree that landfills are necessary, but they do not want to live near them.

9. VECTORS

In landfill parlance, a *vector* is an insect or arthropod, rodent, or other animal of public health significance capable of causing human discomfort or injury, or capable of harboring or transmitting the causative agent of human disease. Vectors include flies, domestic rats, field rodents, mosquitoes, wasps, and cockroaches. Standards for vector control should state the vector thresholds (e.g., "six or more flies per square yard").

10. ULTIMATE LANDFILL DISPOSITION

When filled to final capacity and closed, the covered landfill can be used for grassed green areas, shallow-rooted agricultural areas, and recreational areas (soccer fields, golf, etc.). Light construction uses are also possible, although there may be problems with gas accumulation, corrosion of pipes and foundation piles, and settlement.

Settlement will generally be uneven. Settlement in areas with high rainfall can be up to 20% of the overall landfill height. In dry areas, the settlement may be much less, 2 to 3%. Little information on bearing capacity of landfills is available. Some studies have suggested capacities of 500 to 800 lbf/ft^2 (24 to 38 kPa).

11. LANDFILL GAS

Once covered, the organic material within a landfill cell provides an ideal site for decomposition. Aerobic conditions prevail for approximately the first month. Gaseous products of the initial aerobic decomposition include CO_2 and H_2O. The following are typical reactions involving carbohydrates and stearic acid.

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O \qquad 31.4$$

$$C_{18}H_{36}O_2 + 26O_2 \rightarrow 18CO_2 + 18H_2O \qquad 31.5$$

After the first month or so, the decomposing waste will have exhausted the oxygen from the cell. Digestion continues anaerobically, producing a low-heating value *landfill gas* (LFG) consisting of approximately 50% methane (CH_4), 50% carbon dioxide, and trace amounts of other gases (e.g., CO, N_2, and H_2S). Decomposition occurs at temperatures of 100 to 120°F (40 to 50°C), but may increase to up to 160°F (70°C).

$$C_6H_{12}O_6 \rightarrow 3CO_2 + 3CH_4 \qquad 31.6$$

$$C_{18}H_{36}O_2 + 8H_2O \rightarrow 5CO_2 + 13CH_4 \qquad 31.7$$

LFG is essentially saturated with water vapor when formed. However, if the gas collection pipes are vertical or sloped, some of the water vapor will condense on the pipes and drain back into the landfill. Most of the remaining moisture is removed in condensate traps located along the gas collection system line.

From Dalton's law, the total gas pressure within a landfill is the sum of the partial pressures of the component gases. Partial pressure is volumetrically weighted and can be found from the volumetric fraction, B, of the gas.

$$p_t = p_{CH_4} + p_{CO_2} + p_{H_2O} + p_{N_2} + p_{other} \quad 31.8$$

$$p_i = B_i p_t \quad 31.9$$

If uncontrolled, LFG will migrate to the surface. If the LFG accumulates, an explosion hazard results, since methane is highly explosive in concentrations of 5 to 15% by volume. Thus, methane will pass through the explosive concentration as it is being diluted. Other environmental problems, including objectionable odors, can also occur. Therefore, various methods are used to prevent gas from escaping or spreading laterally.

Landfill gases can be collected by either passive or active methods. *Passive collection* uses the pressure of the gas itself as the driving force. Passive collection is applicable for sites that generate low volumes of gas and where offsite migration of gas is not expected. This generally applies to small municipal landfills—those with volumes less than approximately 50,000 yd^3 (40 000 m^3). Common passive control methods include (a) isolated gas (pressure relief) vents in the landfill cover, with or without a common flare; (b) perimeter interceptor gravel trenches; (c) perimeter barrier trenches (e.g., slurry walls); (d) impermeable barriers within the landfill; and (e) sorptive barriers in the landfill.

Active gas collection draws the landfill gas out with a vacuum from *extraction wells.* Various types of horizontal and vertical wells can be used through the landfill to extract gas in vertical movement, while perimeter facilities are used to extract gases in lateral movement. Vertical wells are usually perforated PVC pipes packed in sleeves of gravel and bentonite clay. PVC pipe is resistant to the chlorine and sulfur compounds present in the landfill.

Determining the location of isolated vents is essentially heuristic—one vent per 10,000 yd^3 (7500 m^3) of landfill is probably sufficient. Regardless, extraction wells should be spaced with overlapping zones of influence. If the *radius of influence*, R, of each well and the desired fractional overlap, O, are known, the spacing between wells is given by Eq. 31.11. For example, if the extraction wells are placed on a square grid with spacing of $L = 1.4R$, the overlap will be 60%. For a 100% overlap, the spacing would equal the radius of influence.

$$\frac{L}{R} = 2 - O \quad 31.10$$

In many locations, the LFG is incinerated in flares. However, emissions from flaring are problematic. Alternatives to flaring include using the LFG to produce hot water or steam for heating or electricity generation. During the 1980s, reciprocating engines and combustion turbines powered by LFG were tried. However, such engines generated relatively high emissions of their own due to impurities and composition variations in the fuel. True Rankine-cycle power plants (generally without reheat) avoid this problem, since boilers are less sensitive to impurities.

One problem with using LFG commercially is that LFG is withdrawn from landfills at less than atmospheric pressure. Conventional furnace burners need approximately 5 psig at the boiler front. Low-pressure burners that require 2 psig are available, but they are expensive. Therefore, some of the plant power must be used to pressurize the LFG in blowers.

Although production is limited, LFG is produced for a long period after a landfill site is closed. Production slowly drops 3 to 5% annually to approximately 30% of its original value after about 20 to 25 yr, which is considered to be the economic life of a gas-reclamation system. The theoretical ultimate production of LFG has been estimated by other researchers as 15,000 ft^3 per ton (0.45 m^3/kg) of solid waste, with an estimated volumetric gas composition of 54% methane and 46% carbon dioxide. However, unfavorable and nonideal conditions in the landfill often reduce this yield to approximately 1000 to 3000 ft^3/ton (0.03 to 0.09 m^3/kg) or even lower.

Table 31.3 *Properties of Methane and Carbon Dioxide*

	CH_4	CO_2
color	none	none
odor	none	none
density, at STP		
(g/L)	0.717	1.977
(lbm/ft^3)	0.0447	0.123

solubility (760 mm Hg, 20°C), volumes in one volume of water	0.33	0.88
solubility, qualitative	slight	moderate

12. LANDFILL LEACHATE

Leachates are liquid wastes containing dissolved and finely suspended solid matter and microbial waste produced in landfills. Leachate becomes more concentrated as the landfill ages. Leachate forms from liquids brought into the landfill, water run-on, and precipitation. Leachate in a natural attenuation landfill will contaminate the surrounding soil and groundwater. In a lined containment landfill, leachate will percolate downward through the refuse and collect at the first landfill liner.

Leachate must be removed to reduce hydraulic head on the liner and to reduce unacceptable concentrations of hazardous substances.

When a layer of liquid sludge is disposed of in a landfill, the consolidation of the sludge by higher layers will cause the water to be released. This released water is known as *pore-squeeze liquid.*

Some water will be absorbed by the MSW and will not percolate down. The quantity of water that can be held against the pull of gravity is referred to as the *field capacity*, FC. The potential quantity of leachate is the amount of moisture within the landfill in excess of the FC.

In general, the amount of leachate produced is directly related to the amount of external water entering the landfill. Theoretically, the leachate generation rate can be determined by writing a water mass balance on the landfill. This can be done on a preclosure and a postclosure basis. Typical units for all the terms are units of length (e.g., "1.2 in of rain") or mass per unit volume (e.g., "a field capacity of 4 lbm/yd^3").

The preclosure leachate generation rate is

$$\begin{aligned}\text{preclosure leachate generation} = {} & \text{moisture released by incoming waste, including pore-squeeze liquid} \\ & + \text{precipitation} \\ & - \text{moisture lost due to evaporation} \\ & - \text{field capacity}\end{aligned} \qquad 31.11$$

The postclosure water balance is

$$\begin{aligned}\text{postclosure leachate generation} = {} & \text{precipitation} \\ & - \text{surface runoff} \\ & - \text{evapotranspiration} \\ & - \text{moisture lost in formation of landfill gas and other chemical compounds} \\ & - \text{water vapor removed along with landfill gas} \\ & - \text{change in soil moisture storage}\end{aligned} \qquad 31.12$$

13. LEACHATE MIGRATION FROM LANDFILLS

From Darcy's law (Chap. 21), migration of leachate contaminants that have passed through liners into aquifers or the groundwater table is proportional to the hydraulic conductivity, K, and the hydraulic gradient, i. Hydraulic conductivities of clay liners are 1.2×10^{-7} to 1.2×10^{-5} ft/hr (10^{-9} to 10^{-7} cm/s). However, the properties of clay liners can change considerably over time due to interactions with materials in the landfill. If the clay dries out (desiccates), it will be much more permeable. For synthetic FMLs, hydraulic conductivities are 1.2×10^{-10} to 1.2×10^{7} ft/hr (10^{-12} to 10^{-9} cm/s). The average permeability of high-density polyethylene is approximately 1.2×10^{-11} ft/hr (1×10^{-13} cm/s).

$$Q = KiA \qquad 31.13$$

$$i = \frac{dH}{dL} \qquad 31.14$$

14. GROUNDWATER DEWATERING

It may be possible to prevent or reduce contaminant migration by reducing the elevation of the groundwater table (GWT). This is accomplished by dewatering the soil with relief-type *extraction drains (relief drains).* The *ellipse equation*, also known as the *Donnan formula*, used for calculating pipe spacing, L, in draining agricultural fields, can be used to determine the spacing of groundwater dewatering systems. In Eq. 31.16, K is the hydraulic conductivity with units of length/time, a is the distance between the pipe and the impervious layer barrier (a is zero if the pipe is installed on the barrier), b is the maximum allowable table height above the barrier, and Q is the *recharge rate*, also known as the *drainage coefficient*, with dimensions of length/time. The units of K and Q must be on the same time basis.

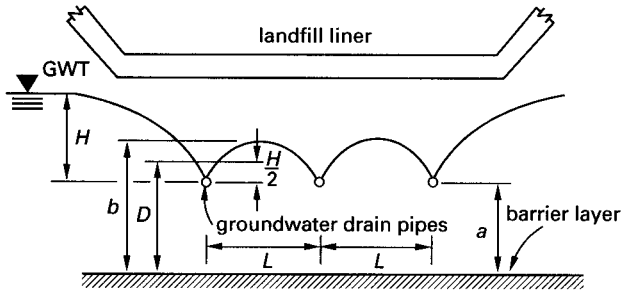
$$L = 2\sqrt{\left(\frac{K}{Q}\right)(b^2 - a^2)} = 2\sqrt{\frac{b^2 - a^2}{i}} \qquad 31.15$$

Equation 31.15 is often used because of its simplicity, but the accuracy is only approximately ± 20%. Therefore, the calculated spacing should be decreased by 10 to 20%.

For pipes above the impervious stratum, the total discharge per unit length of each pipe (in ft^3/sec-ft or m^3/s·m) is given by Eq. 31.16. H is the maximum height of the water table above the pipe invert elevation. D is the average depth of flow.

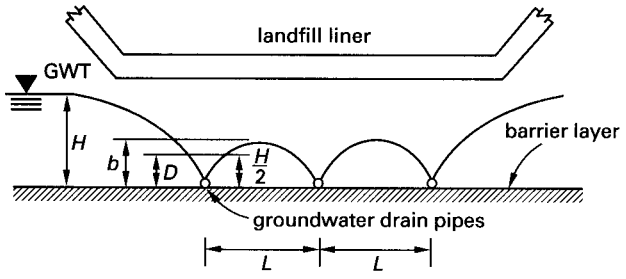
$$Q_{\text{unit length}} = \frac{2\pi KHD}{L} \qquad 31.16$$

$$D = a + \frac{H}{2} \qquad 31.17$$



For pipes on the impervious stratum, the total discharge per unit length from the ends of each pipe (in ft^3/sec-ft or m^3/s·m) is

$$Q_{\text{unit length}} = \frac{4KH^2}{L} \qquad 31.18$$



Equation 31.19 gives the total discharge per pipe. If the pipe drains from both ends, the discharge per end would be half of that amount.

$$Q_{\text{pipe}} = LQ_{\text{unit length}} \qquad 31.19$$

Environmental

15. LEACHATE RECOVERY SYSTEMS

At least two distinct leachate recovery systems are required in landfills: one within the landfill to limit the hydraulic head of leachate that has reached the top liner, and another to catch the leachate that has passed through the top liner and drainage layer and has reached the bottom liner.

By removing leachate at the first liner, the hydrostatic pressure on the liner is reduced, minimizing the pressure gradient and hydraulic movement through the liner. A pump is used to raise the collected leachate to the surface once a predetermined level has been reached. Tracer compounds (e.g., lithium compounds or radioactive hydrogen) can be buried with the wastes to signal migration and leakage.

Leachate collection and recovery systems fail because of clogged drainage layers and pipe, crushed collection pipes due to waste load, pump failures, and faulty design.

16. LEACHATE TREATMENT

Leachate is essentially a very strong municipal wastewater, and it tends to become more concentrated as the landfill ages. Leachate from landfills contains extremely high concentrations of compounds and cannot be discharged directly into rivers or other water sources.

Leachate is treated with biological (i.e., trickling filter and activated sludge) and physical/chemical processes very similar to those used in wastewater treatment plants. For large landfills, these treatment facilities are located on the landfill site. A typical large landfill treatment facility would include an equalization tank, a primary clarifier, a first-stage activated sludge aerator and clarifier, a second-stage activated sludge aerator and clarifier, and a rapid sand filter. Additional equipment for sludge dewatering and digestion would also be required. Liquid effluent would be discharged to the municipal wastewater treatment plant.

17. LANDFILL MONITORING

Monitoring is conducted at sanitary landfills to ensure that no contaminants are released from the landfill. Monitoring is conducted in the vadose zone for gases and liquid, in the groundwater for leachate movements, and in the air for air quality monitoring.

Landfills use *monitoring wells* located outside of the covered cells and extending past the bottom of the disposal site into the aquifer. In general, individual monitoring wells should extend into each stratum upstream and downstream (based on the hydraulic gradient) of the landfill.

18. CARBON DIOXIDE IN LEACHATE

Carbon dioxide is formed during both aerobic and anaerobic decomposition. Carbon dioxide combines with water to produce *carbonic acid*, H_2CO_3. In the absence of other mitigating compounds, this will produce a slightly acidic leachate.

The concentration of carbon dioxide (in mg/L) in the leachate (assumed to be water) can be calculated from the *absorption coefficient* (*solubility*), K_s. The absorption coefficient for carbon dioxide at 32°F (0°C) and 1 atm is approximately $K_s = 0.88$ L/L. This can be converted to mg/L with the ideal gas law.

$$\frac{m_g}{V_L} = \frac{p(\text{MW})}{R^* T} = \frac{B_{CO_2} p_t \left(44 \frac{\text{g}}{\text{mol}}\right)}{\left(0.08206 \frac{\text{atm-L}}{\text{mol-K}}\right) T_K} \qquad 31.20$$

$$T_K = T_{°C} + 273 \qquad 31.21$$

At a typical internal landfill temperature of 100°F (38°C), this equation reduces to

$$\frac{m_g}{V_L} = 1.72 B_{CO_2} \qquad 31.22$$

The concentration of carbon dioxide in the leachate is

$$C_{CO_2,\text{mg/L}} = \left(\frac{m_g}{V_L}\right) K_{s,\text{L/L}} \left(1000 \frac{\text{mg}}{\text{g}}\right) \qquad 31.23$$

Table 31.4 *Typical Absorption Coefficients (L/L at 0°C and 1 atm)*

hydrogen	0.017
nitrogen	0.015
oxygen	0.028
carbon monoxide	0.025
methane	0.33
carbon dioxide	0.88

19. INCINERATION OF MUNICIPAL SOLID WASTE

Incineration of MSW results in a 90% reduction in waste disposal volume and a mass reduction of 75%.

In *no-boiler incinerators*, MSW is efficiently burned without steam generation. However, incineration at large installations is often accompanied by recycling and steam and/or electrical power generation. Incinerator/generator facilities with separation capability are known as *resource-recovery plants*. Facilities with boilers are referred to as *waste-to-steam plants*. Facilities with boilers and electrical generators are referred to as *waste-to-energy (WTE) facilities*. In WTE plants, the combustion heat is used to generate steam and electrical power.

Mass burning is the incineration of unprocessed MSW, typically on stoker grates or in rotary and waterwall combustors to generate steam. With mass burning, MSW is unloaded into a pit and then moved by crane to the furnace conveying mechanism. Approximately 27% of the MSW remains as ash, which consists of glass, sand, stones, aluminum, and other noncombustible materials. It and the flyash are usually collected and disposed of in municipal landfills. (The U.S. Environmental Protection Agency (EPA) has ruled that ash from the incineration of MSW is not a hazardous waste. However, this is hotly contested and is subject to ongoing evaluation.) Capacities of typical mass burn units vary from less than 400 tons/day (360 Mg/d) to a high of 3000 tons/day (2700 Mg/d), with the majority of units processing 1000 to 2000 tons/day (910 to 1800 Mg/d).

MSW, as collected, has a heating value of approximately 4500 Btu/lbm (10 MJ/kg), though higher values have been reported. For 1000 tons/day (1000 Mg/d) of MSW incinerated, the yields are approximately 150,000 to 200,000 lbm/hr (75 to 1000 Mg/h) of 650 to 750 psig (4.5 to 5.2 MPa) steam at 700 to 750°F (370 to 400°C) and 25 to 30 MW (27.6 to 33.1 MW) of gross electrical power. Approximately 10% of the electrical power is used internally, and units generating much less than approximately 10 MW (gross) may use all of their generated electrical power internally.

The *burning rate* varies from approximately 40 to 60 lbm/hr-ft^2 (200 to 300 kg/h·m^2) and is the fueling rate divided by the total effective grate area. Maximum heat release rates are approximately 300,000 Btu/hr-ft^2 (940 kW/m^2). The *heat release rate*, HRR, is defined as

$$\text{HRR} = \frac{(\text{fueling rate})(\text{HV})}{\text{total effective grate area}} \qquad 31.24$$

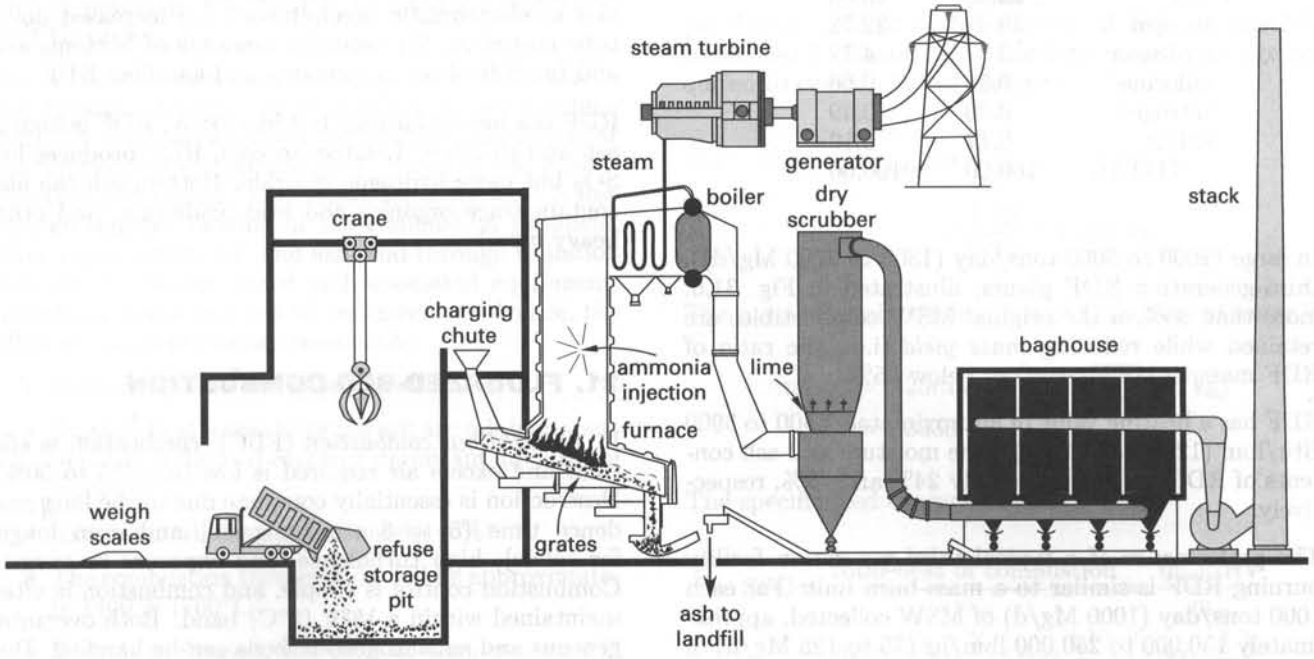

Figure 31.5 *Typical Mass-Burn Waste-to-Energy Plant*

20. REFUSE-DERIVED FUEL

Refuse-derived fuel (RDF) is derived from MSW. First-generation RDF plants use "crunch and burn" technology. In these plants, the MSW is shredded after ferrous metals are removed magnetically. First-generation RDF plants suffer from the same problems that have plagued early mass burn units, including ash with excessive quantities of noncombustible materials such as glass, grit and sand, and aluminum.

Second-generation plants incorporate screens and air classifiers to reduce noncombustible materials and to increase the recovery of some materials. *Material recovery facilities* (MRFs) specialize in sorting out recyclables from MSF. The ash content is reduced, and the energy content of the RDF is increased. The MSW is converted into RDF pellets $2\frac{1}{2}$ to 6 in (6.4 to 15 cm) in size and is introduced through feed ports above a traveling grate. Some of fuel is burned in suspension, with the rest burned on the grate. Grate speed is varied so that the fuel is completely incinerated by the time it reaches the ash rejection ports at the front of the burner.

Table 31.5 *Typical Ultimate Analyses of MSW and RDF*

	percentage by weight	
element	MSW	RDF
carbon	26.65	31.00
water	25.30	27.14
ash	23.65	13.63
oxygen	19.61	22.72
hydrogen	3.61	4.17
chlorine	0.55	0.66
nitrogen	0.46	0.49
sulfur	0.17	0.19
TOTAL	100.00	100.00

In large (2000 to 3000 tons/day (1800 to 2700 Mg/d)), third-generation RDF plants, illustrated in Fig. 31.6, more than 95% of the original MSW combustibles are retained while reducing *mass yield* (i.e., the ratio of RDF mass to MSW mass) to below 85%.

RDF has a heating value of approximately 5500 to 5900 Btu/lbm (12 to 14 MJ/kg). The moisture and ash contents of RDF are approximately 24% and 12%, respectively.

The performance of a typical third-generation facility burning RDF is similar to a mass-burn unit: For each 1000 tons/day (1000 Mg/d) of MSW collected, approximately 150,000 to 250,000 lbm/hr (75 to 125 Mg/h) of 750 to 850 psig (5.2 to 5.9 Mpa) steam at 750 to 825°F (400 to 440°C) can be generated, resulting in approximately 30 to 40 MW (33.1 to 44.1 MW) of electrical power.

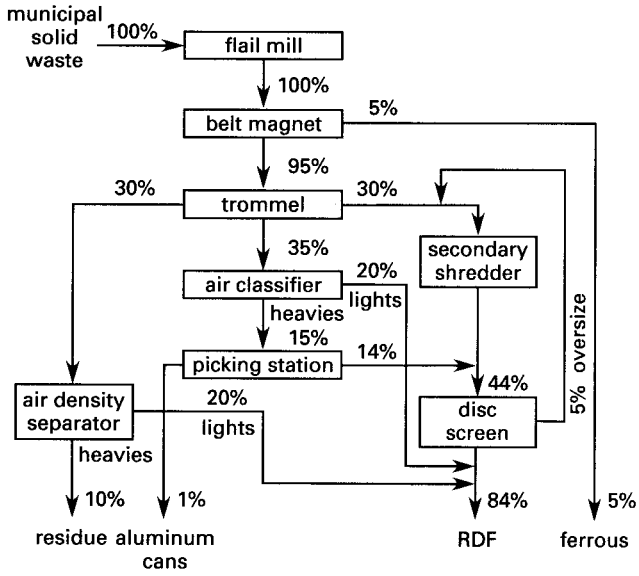

Figure 31.6 *Typical RDF Processing*

Natural gas is introduced at startup to bring the furnace up to the required 1800°F (1000°C) operating temperature. Natural gas can also be used upon demand, as when a load of particularly wet RDF lowers the furnace temperature.

Coal, oil, or natural gas can be used as a back-up fuel if RDF is unavailable or as an intended part of a *co-firing* design. Co-firing installations are relatively rare, and many have discontinued burning RDF due to poor economic performance. Typical problems with co-firing are (a) upper furnace wall slagging, (b) decreased efficiencies in electrostatic precipitators, (c) increased boiler tube corrosion, (d) excessive amounts of bottoms ash, and (e) difficulties in receiving and handling RDF.

RDF is a low-sulfur fuel, but like MSW, RDF is high in ash and chlorine. Relative to coal, RDF produces less SO_2 but more hydrogen chloride. Bottom ash can also contain trace organics and lead, cadmium, and other heavy metals.

21. FLUIDIZED-BED COMBUSTION

In *fluidized-bed combustion* (FBC), combustion is efficient and excess air required is low (e.g., 25 to 50%). Destruction is essentially complete due to the long residence time (5 to 8 sec for gases, and even longer for solids), high turbulence, and exposure to oxygen. Combustion control is simple, and combustion is often maintained within a 15°F (8°C) band. Both overautogeneous and subautogenous feeds can be handled. Due to the thermal mass of the bed, the FBC temperature drops slowly—at the rate of about 10°F/hr (5°C/h) after shut-down. Start-up is fast and operation can be intermittent.

Relative to other hazardous waste disposal methods, NOx and metal emissions are low, and organic content of the ash is very low (e.g., below 1%). Because of the long residence time, FBC systems do not usually require afterburners or *secondary combustion chambers* (SCCs). Due to the turbulent combustion process, the combustion temperature can be 200 to 300°F (110 to 170°C) lower than in rotary kilns. These factors translate into fuel savings, fewer or no NOx emissions, and lower metal emissions.

Most limitations of FBC systems relate to the feed. The feed must be small in size and roughly regular in shape so that it can be fluidized. This makes FBCs ideal for non-atomizable liquids, slurries, sludges, tars, and granular solids. It is more appropriate (and economical) to destroy atomizable liquid wastes in a boiler or special injection furnace and large bulky wastes in a rotary kiln or incinerator.

FBCs cannot usually be used when the feed material or its ash melts below the bed temperature. If the feed melts, it will agglomerate and defluidize the bed. When it is necessary to burn a feed with a low melting temperature, two methods can be used. The bed can be operated as a *chemically active bed*, where operation is close to but below the ash melting point of 1350°F to 1450°F (730°C to 790°C). A small amount of controlled melting is permitted to occur, and the agglomerated ash is removed.

When a higher temperature is desired in order to destroy hazardous materials, the melting point of feed can be increased by injecting low-cost additives (e.g., calcium hydroxide or kaolin clay). These combine with alkali metals salts to form refractory-like materials with melting points in the 1950°F to 2350°F (1070°C to 1290°C) range.

The design of a fluidizing-bed incinerator starts with a heat balance. Energy enters the FBC during combustion of the feed and auxiliary fuel and from sensible heat contributions of the air and fuel. Some of the heat is recovered and reused. The remainder of the heat is lost through sensible heating of the combustion products, water vapor, excess air, and ash, and through radiation from the combustor vessel and associated equipment. Since these items may not all be known in advance, the following assumptions are reasonable.

- Radiation losses are approximately 5%.
- Sensible heat losses from the ash are minimal, particularly if the feed contains significant amounts of moisture.
- Excess air will be approximately 40%.
- The combustion temperature will be approximately 1400°F (760°C).
- If air is preheated, the preheat temperature will be approximately 1000°F (540°C).

The fuel's *specific feed characteristic* (SFC) is the ratio of the higher (gross) heating value to the moisture content. Typical values range from a low of approximately 1000 Btu/lbm (2300 kJ/kg) for wastewater treatment plant biosolids to over 60,000 Btu/lbm (140 MJ/kg) for barks, sawdust, and RDF. (Although the units are the same, the specific feed characteristic is not the same as the heating value.) Making the previous assumptions and using the SFC as an indicator, the following generalizations can be made.

- Fuels with an SFC less than 2600 Btu/lbm (6060 kJ/kg) require a 1000°F (540°C) hot windbox, and are autogeneous at that value and subautogeneous below that value. The SFC drops to 2400 Btu/lbm (5600 kJ/kg) with air preheated to 1200°F (650°C). Below the subautogeneous SFC, water evaporation is the controlling design factor and auxiliary fuel is required.
- Fuels with an SFC of 4000 Btu/lbm (9300 kJ/kg) are autogeneous with a cold windbox and are overautogeneous above that value. Combustion is the controlling design factor for overautogenous SFCs.

Example 31.1

A wastewater treatment sludge is dewatered to 75% water by weight. The solids have a heating value of 6500 Btu/lbm (15 000 kJ/kg). The dewatered sludge enters a fluidized-bed combustor with a 1000°F (540°C) windbox at the rate of 15,000 lbm/hr (1.9 kg/s). (a) What is the specific feed characteristic? (b) Approximately what energy (in Btu/hr) must the auxiliary fuel supply?

SI Solution

(a) The dewatered sludge consists of 25% combustible solids and 75% moisture. The total mass of sludge required to contain 1.0 kg water is

$$\begin{aligned} m_{\text{sludge}} &= \frac{m_w}{x_w} \\ &= \frac{1\ \text{kg}}{0.75} = 1.333\ \text{kg} \end{aligned}$$

The mass of combustible solids per kilogram of water is

$$\begin{aligned} m_{\text{solids}} &= 0.25 m_{\text{sludge}} = (0.25)(1.333\ \text{kg}) \\ &= 0.3333\ \text{kg} \end{aligned}$$

The specific feed characteristic is

$$\begin{aligned} \text{SFC} &= \frac{\text{total heat of combustion}}{m_w} = \frac{m_{\text{solid}}\text{HV}}{m_w} \\ &= \frac{(0.3333\ \text{kg})\left(15\,000\ \frac{\text{kJ}}{\text{kg}}\right)\left(1000\ \frac{\text{J}}{\text{kJ}}\right)}{1\ \text{kg}} \\ &= 5.0 \times 10^6\ \text{J/kg} \end{aligned}$$

(b) Making the listed assumptions, operation with a 540°C hot windbox requires an SFC of approximately 6060 kJ/kg. Therefore, the energy per kilogram of water in the fuel that an auxiliary fuel must provide is

$$(6060 \text{ kJ})\left(1000 \frac{\text{J}}{\text{kJ}}\right) - 5 \times 10^6 \text{ J} = 1.06 \times 10^6 \text{ J}$$

The energy supplied by the auxiliary fuel is

$$\begin{aligned}\dot{m}_{\text{fuel}} x_w \times \text{SFC deficit} &= \left(1.9 \frac{\text{kg}}{\text{s}}\right)(0.75)\left(1.06 \times 10^6 \frac{\text{J}}{\text{kg}}\right) \\ &= 1.51 \times 10^6 \text{ J/s} \quad (1.5 \text{ MW})\end{aligned}$$

Customary U.S. Solution

(a) The dewatered sludge consists of 25% combustible solids and 75% moisture. The total mass of sludge required to contain 1.0 lbm water is

$$\begin{aligned}m_{\text{sludge}} &= \frac{m_w}{x_w} \\ &= \frac{1 \text{ lbm}}{0.75} = 1.333 \text{ lbm}\end{aligned}$$

The mass of combustible solids per pound of water is

$$\begin{aligned}m_{\text{solids}} &= 0.25 m_{\text{sludge}} = (0.25)(1.333 \text{ lbm}) \\ &= 0.3333 \text{ lbm}\end{aligned}$$

The specific feed characteristic is

$$\begin{aligned}\text{SFC} &= \frac{\text{total heat of combustion}}{m_w} = \frac{m_{\text{solid}} \text{HV}}{m_w} \\ &= \frac{(0.3333 \text{ lbm})\left(6500 \frac{\text{Btu}}{\text{lbm}}\right)}{1 \text{ lbm}} \\ &= 2166 \text{ Btu/lbm}\end{aligned}$$

(b) Making the listed assumptions, operation with a 1000°F hot windbox requires an SFC of approximately 2600 Btu/lbm. Therefore, the energy per pound of water in the fuel that an auxiliary fuel must provide is

$$2600 \text{ Btu} - 2166 \text{ Btu} = 434 \text{ Btu}$$

The energy supplied by the auxiliary fuel is

$$\begin{aligned}\dot{m}_{\text{fuel}} x_w \times \text{SFC deficit} &= \left(15{,}000 \frac{\text{lbm}}{\text{hr}}\right)(0.75)\left(434 \frac{\text{Btu}}{\text{lbm}}\right) \\ &= 4.88 \times 10^7 \text{ Btu/hr}\end{aligned}$$

PRACTICE PROBLEMS

Landfills

1. A town has a current population of 10,000, which is expected to grow linearly, doubling in population during the next 15 years. The town intends to dispose of its municipal solid waste in a 30-acre landfill that will be converted to a park in 20 yr. Solid waste is generated at the rate of 5 lbm/capita-day. The average compacted density in the landfill will be 1000 lbm/yd^3. Disregarding any soil addition for cover and cell construction, how long will it take to fill the landfill to a uniform height of 6 ft?

(A) 2100 days
(B) 4200 days
(C) 6300 days
(D) 9500 days

The answer is (B).

2. (*Time limit: one hour*) A town of 10,000 people has selected a square landfill site to deposit its solid waste. The minimum unused side borders are 50 ft. The landfill currently consists of a square 50-acre depression with an average depth of 20 ft below the surrounding grade. When the landfill is at final capacity, it will be covered with 10 ft of earth cover. The maximum height of the covered landfill is 20 ft above the surrounding grade. Solid waste is generated at the rate of 5 lbm/capita-day. The average compacted density in the landfill will be 1000 lbm/yd^3.

(a) What is the volumetric capacity of the landfill site?

(A) 1.1×10^6 ft^3
(B) 6.5×10^6 ft^3
(C) 3.1×10^7 ft^3
(D) 5.7×10^7 ft^3

The answer is (D).

(b) Using a loading factor of 1.25, what is the volume of landfill used each day?

(A) 60 yd^3/day
(B) 120 yd^3/day
(C) 180 yd^3/day
(D) 240 yd^3/day

The answer is (A).

(c) What is the service life of the landfill site?

(A) 30 yr
(B) 45 yr
(C) 60 yr
(D) 90 yr

The answer is (D).

Part 1: General Concepts

Pollution prevention (sometimes referred to as "P2") can be achieved in a number of ways. The most desirable method is reduction at the source. Reduction is accomplished through process modifications, raw material quantity reduction, substitution of materials, improvements in material quality, and increased efficiencies. However, traditional *end-of-pipe* treatment and disposal processes after the pollution is generated remain the main focus. *Pollution control* is the limiting of pollutants in a planned and systematic manner.

Table 32.1 *Pollution Prevention Hierarchy (from most to least desirable)*

source reduction
recycling
waste separation and concentration
waste exchange
energy/material recovery
waste treatment
disposal

Pollution control, hazardous waste, and other environmental regulations vary from nation to nation and are constantly changing. Therefore, regulation-specific issues, including timetables, permit application processes, enforcement, and penalties for violations, are either omitted from this chapter or discussed in general terms. For a similar reason, few limits on pollutant emission rates and concentrations are given in this chapter.[1] Those that are given should be considered merely representative and typical of the general range of values.

Part 2: Types and Sources of Pollution

2. THE ENVIRONMENT

Specific regulations often deal with parts of the *environment*, such as the atmosphere (i.e., the "air"), oceans and other surface water, subsurface water, and the soil. *Nonattainment areas* are geographical areas identified

[1]Another factor complicating the publication of specific regulations is that the maximum-permitted concentrations and emissions depend on the size and nature of the source.

by regulation that already do not currently meet *national ambient air quality standards* (NAAQS). Nonattainment is usually the result of geography, concentrations of industrial facilities, and excessive vehicular travel, and can apply to any of the regulated substances (e.g., ozone, oxides of sulfur and nitrogen, and heavy metals).

3. POLLUTANTS

A *pollutant* is a material or substance that is accidentally or intentionally introduced to the environment in a quantity that exceeds what occurs naturally. Not all pollutants are toxic or hazardous, but the issue is moot when regulations limiting permissible concentrations are specific. As defined by regulations in the United States, *hazardous air pollutants* (HAPs), also known as *air toxics*, consist of trace metals (e.g., lead, beryllium, mercury, cadmium, nickel, and arsenic) and other substances for a total of approximately 200 "listed" substances.[2]

Another categorization defined by regulation in the United States separates pollutants into *criteria pollutants* (e.g., sulfur dioxide, nitrogen oxides, carbon monoxide, volatile organic compounds, particulate matter, and lead) and *noncriteria pollutants* (e.g., fluorides, sulfuric acid mist, reduced sulfur compounds, vinyl chloride, asbestos, beryllium, mercury, and other heavy metals).

4. WASTES

Process wastes are generated during manufacturing. *Intrinsic wastes* are part of the design of the product and manufacturing process. Examples of intrinsic wastes are impurities in the reactants and raw materials, byproducts, residues, and spent materials. Reduction of intrinsic wastes usually means redesigning the product or manufacturing process. *Extrinsic wastes*, on the other hand, are usually reduced by administrative controls, maintenance, training, or recycling. Examples of extrinsic wastes are fugitive leaks and discharges during material handling, testing, or process shutdown.

Solid wastes are garbage, refuse, biosolids, and containerized solid, liquid, and gaseous wastes.[3] *Hazardous waste* is defined as solid waste, alone or in combination with other solids, that because of its quantity, concentration, or physical, chemical, or infectious characteristics may either (a) cause an increase in mortality or serious (irreversible or incapacitating) illness, or (b) pose a present or future hazard to health or the environment when improperly treated, stored, transported, disposed of, or managed.

A substance is *reactive* if it reacts violently with water; if the pH is less than 2 or greater than 12.5, it is *corrosive*; if its flash point is less than 140°F (60°C), it is *ignitable*. The *toxicity characteristic leaching procedure* (TCLP)[4] test is used to determine if the substance is *toxic*. The TCLP tests for the presence of 8 metals (e.g., chromium, lead, and mercury) and 25 organic compounds (e.g., benzene and chlorinated hydrocarbons).

Hazardous wastes can be categorized by the nature of their sources. *F-wastes* (e.g., spent solvents and distillation residues) originate from nonspecific sources; *K-wastes* (e.g., separator sludge from petroleum refining) are generated from industry-specific sources; *P-wastes* (e.g., hydrogen cyanide) are acutely hazardous discarded commercial products, off-specification products, and spill residues; *U-wastes* (e.g., benzene and hydrogen sulfide) are other discarded commercial products, off-specification products, and spill residues.

Two notable "rules" pertain to hazardous wastes. The *mixture rule* states that any solid waste mixed with hazardous waste becomes hazardous. The *derived from rule* states that any waste derived from the treatment of a hazardous waste (e.g., ash from the incineration of hazardous waste) remains a hazardous waste.[5]

5. POLLUTION SOURCES

A *pollution source* is any facility that produces pollution. A *generator* is any facility that generates hazardous waste. The term "major" (i.e., a *major source*) is defined differently for each class of nonattainment areas.[6]

The combustion of fossil fuels (e.g., coal, fuel oil, and natural gas) to produce steam in electrical generating plants is the most significant source of air-borne pollution. As such, this industry is among the most highly regulated.

Specific regulations pertain to generators of hazardous waste. Generators of more than certain amounts (e.g., 100 kg/month) must be registered (i.e., with the Environmental Protection Agency, EPA). Restrictions are placed on generators in the areas of storage, personnel training, shipping, treatment, and disposal.

[2]The most dangerous air toxics include asbestos, benzene, cadmium, carbon tetrachloride, chlorinated dioxins and dibenzofurans, chromium, ethylene dibromide, ethylene dichloride, ethylene oxide and methylene chloride, radionuclides, vinyl chloride, and emissions from coke ovens. Most of these substances are carcinogenic.

[3]The term *biosolids* is replacing the term *sludge* as it refers to organic waste produced from biological wastewater treatment processes. Sludge from industrial processes and flue gas cleanup (FGC) devices retains its name.

[4]Probably no subject in this book has more acronyms than environmental engineering. All of the acronyms used in this chapter are in actual use; none were invented for the benefit of the chapter.

[5]Hazardous waste should not be incinerated with nonhazardous waste, as all of the ash would be considered hazardous by these rules.

[6]A nonattainment area is classified as marginal, moderate, serious, severe, or extreme based on the average pollution (e.g., ozone) level measured in the area.

6. ENVIRONMENTAL IMPACT REPORTS

New installations and large-scale construction projects must be assessed for potential environmental damage before being approved by state and local building officials. The assessment is documented in an *environmental impact report* (EIR). The EIR evaluates all of the potential ways that a project could affect the ecological balance and environment. A report that alleges the absence of any environmental impacts is known as a *negative declaration* ("negative dec").

The following questions and issues are typically addressed in an EIR.

1. the nature of the proposed project
2. the nature of the project area, including distinguishing natural and man-made characteristics
3. current and proposed percentage uses by zoning: residential, commercial, industrial, public, and planned development
4. current and proposed percentage uses by application: built-up, landscaped, agricultural, paved streets and highways, paved parking, surface and aerial utilities, railroad, and vacant and unimproved
5. the nature and degree that the earth will be altered: (a) changes in topology from excavation and earth movement to and from the site, (b) changes in slope, (c) changes in chemical composition of the soil, and (d) changes in structural capacity of the soil as a result of compaction, tilling, shoring, or moisture content
6. the nature of known geologic hazards such as earthquake faults and soil instability (subsidence, landslides, and severe erosion)
7. increases in dust, smoke, or air pollutants generated by hauling during construction
8. changes in path, direction, and capacity of natural draining or tendency to flood
9. changes in erosion rates on and off the site
10. the extent to which the project will affect the potential use, extraction, or conservation of the earth's resources, such as crops, minerals, and groundwater
11. after construction is complete, the nature and extent to which the completed project's sewage, drainage, airborne particulate matter, and solid waste will affect the quality and characteristics of the soil, water, and air in the immediate project area and in the surrounding community
12. the quantity and source of fresh water consumed as a result of the project
13. effects on the plant and animal life currently onsite
14. effects on any unique (i.e., not found anywhere else in the city, county, state, or nation) natural or man-made features
15. effect on any historically significant or archeological site
16. changes to the view of the site from points around the project
17. changes affecting wilderness use, open space, landscaping, recreational use, and other aesthetic considerations
18. effects on the health and safety of the people in the project area
19. changes to existing noise levels
20. changes in the number of people who will (a) live or (b) work in the project area
21. changes in the burden placed on roads, highways, intersections, railroads, mass transit, or other elements of the transportation system
22. changes in the burden placed on other municipal services, including sewage treatment; health, fire, and police services; utility companies; etc.
23. the extent to which hazardous materials will be involved, generated, or disposed of during or after construction

Part 3: Environmental Issues

7. INTRODUCTION

Engineers face many environmental issues. This part of the chapter discusses (in alphabetical order) some of them. In some cases, "listed substances" (e.g., those that are specifically regulated) are discussed. In other cases, environmental issues are discussed in general terms.

Environmental engineering covers an immense subject area, and this chapter is merely an introduction to some of the topics. Some subjects "belong" to other engineering disciplines. For example, coal-fired plants are typically designed by mechanical engineers. Other subjects, such as the storage and destruction of nuclear wastes, are specialized topics subject to changing politics, complex legislation, and sometimes-untested technologies. Finally, some wastes are considered nonhazardous industrial wastes and are virtually unregulated. They are not discussed in this chapter either. Processing of medical wastes, personal safety, and the physiological effects of exposure, as important as they are, are beyond the scope of this chapter.

Other philosphical and political issues, such as nuclear fuel versus fossil fuel, plastic bags versus paper bags, and disposable diapers versus cloth diapers, are similarly not covered.

8. ACID GAS

Acid gas generally refers to *sulfur trioxide*, SO_3, in flue gas.[7,8] *Sulfuric acid*, H_2SO_4, formed when sulfur trioxide combines with water, has a low vapor pressure and, consequently, a high boiling point. Hydrochloric (HCl), hydrofluoric (HF), and nitric (HNO_3) acids also form in smaller quantities. However, unlike sulfuric acid, they do not lower the vapor pressure of water significantly. Therefore, any sulfuric acid present will control the dew point.

Sulfur trioxide has a large affinity for water, forming a strong acid even at very low concentrations. At the elevated temperatures in a stack, sulfuric acid attacks steel, almost all plastics, cement, and mortar. Sulfuric acid can be prevented from forming by keeping the temperature of the flue gas above the dew-point temperature. This may require preheating equipment prior to start-up and postheating during shutdown.

Hydrochloric acid does not normally occur unless the fuel has a high chlorine content, as do chlorinated solvents, municipal solid wastes (MSW), and refuse-derived fuels (RDF). Hydrochloric acid formed during the combustion of MSW and RDF can be removed by semidry scrubbing. HCl removal efficiencies of 90 to 99% are common. (See also Acid Rain and Sulfur Oxides.)

9. ACID RAIN

Acid rain consists of weak solutions of sulfuric, hydrochloric, and to a lesser extent, nitric acids. These acids are formed when emissions of sulfur oxides (SOx), hydrogen chloride (HCl), and nitrogen oxides (NOx) return to the ground in rain, fog, or snow, or as dry particles and gases. Acid rain affects lakes and streams, damages buildings and monuments, contributes to reduced visibility, and affects certain forest tree species. Acid rain may also represent a health hazard. (See also Acid Gas and Sulfur Oxides.)

10. ALLERGENS AND MICROORGANISMS

Allergens such as molds, viruses, bacteria, animal droppings, mites, cockroaches, and pollen can cause allergic reactions in humans. One form of bacteria, *legionella*, causes the potentially fatal *Legionnaire's disease*. Inside buildings, allergens and microorganisms become particularly concentrated in standing water, carpets, HVAC filters and humidifier pads, and in locations where birds and rodents have taken up residence. Legionella bacteria can also be spread by aerosol mists generated by cooling towers and evaporative condensers if the bacteria are present in the recirculating water.

Some buildings cause large numbers of people to simultaneously become sick, particularly after a major renovation or change has been made. This is known as *sick building syndrome* or *building-related illness*. This phenomenon can be averted by using building materials that do not release vapor over time (e.g., as does plywood impregnated with formaldehyde) or harbor other irritants. Carpets can accumulate dusts. Repainting, wallpapering, and installing of new flooring can release new airborne chemicals. Areas must be flushed with fresh air until all noticeable effects have been eliminated.

Care must also be taken to ensure that filters in the HVAC system do not harbor microorganisms and are not contaminated by bird or rodent droppings. Air intakes must not be located near areas of chemical storage or parking garages.

11. ASBESTOS

Asbestos is a fibrous silicate mineral material that is inert, strong, and incombustible. Once released into the air, its fibers are light enough to stay airborne for a long time.

Asbestos has typically been used in woven and compressed forms in furnace insulation, gaskets, pipe coverings, boards, roofing felt, and shingles, and has been used as a filler and reinforcement in paint, asphalt, cement, and plastic. Asbestos is no longer banned outright in industrial products. However, regulations, well-publicized health risks associated with cancer and *asbestosis*, and potential liabilities have driven producers to investigate alternatives.

No single product has emerged as a suitable replacement for all asbestos applications. (Almost all replacements are more costly.) *Fiberglass* is an insulator with superior tensile strength but low heat resistance. Fiberglass has a melting temperature of approximately 1000°F (538°C). However, fiberglass treated with hydrochloric acid to leach out most of the silica (SiO_2) can withstand 2000 to 3500°F (1090 to 1930°C).

In typical static sealing applications, *aramid fibers* (known by the trade names Kevlar™ and Twaron™) are particularly useful up to approximately 800°F (427°C). However, aramid fibers cannot withstand the caustic, high-temperature environment encountered in curing concrete.

Table 32.2 lists asbestos substitutes by application.

[7]The term *stack gas* is used interchangeably with *flue gas*.
[8]Sulfur dioxide normally is not a source of acidity in the flue gas.

Table 32.2 Asbestos Substitutes

application	substitute material
insulation boards	mineral wool, fiberglass, foams (polyurethane, cellulose, styrene, and polyimide)
braided packing seals	polytetrafluoroethylene (PTFE), carbon, graphite
flange and furnace door gaskets	*reinforcing fibers*: cellulose, carbon, glass, polyvinyl alcohol, polyamide, polyester, polyacrylonitrile, aramid, and polyolefin; *binders*: nitrile butadiene rubber (NBR)
concrete filler; flame retardant	fiberglass, graphite, polypropylene, acrylics
thixotropic[a] agent in paints, coatings, adhesives, and sealants	polyethylene
additive to plastics and fiberglass to improve heat resistance	vermiculite

[a] A *thixotropic substance* is thick and gel-like when stationary but becomes free-flowing when stirred or agitated.

12. BOTTOM ASH

Ash is the residue left after combustion of a fossil fuel. *Bottom ash* (*bottoms ash* or *bottoms*) is the ash that is removed from the combustor after a fuel is burned. (The rest of the ash is flyash.) The ash falls through the combustion grates into quenching troughs below. It may be continuously removed by *submerged scraper conveyors* (SSCs), screw-type devices, or ram dischargers. The ash can be dewatered to approximately 15% moisture content by compression or by being drawn up a dewatering slope. Bottom ash is combined with conditioned flyash on the way to the ash storage bunker.[9] Most combined ash is eventually landfilled.

13. DISPOSAL OF ASH

Combined ash (bottom ash and flyash) is usually landfilled. Other occasional uses for high-quality combustion ash (not ash from the incineration of municipal solid waste) include roadbed subgrades, road surfaces ("ashphalt"), and building blocks.

[9] Approximately half of the electrical generating plants in the United States use wet flyash handling.

14. CARBON DIOXIDE

Carbon dioxide, though an environmental issue, is not a hazardous material and is not regulated as a pollutant.[10] Carbon dioxide is not an environmental or human toxin, is not flammable, and is not explosive. Skin contact with solid or liquid carbon dioxide presents a freezing hazard. Other than the remote potential for causing frostbite, carbon dioxide has no long-term health effects. Its major hazard is that of asphyxiation, by excluding oxygen from the lungs.

15. CARBON MONOXIDE

Carbon monoxide, CO, is formed during incomplete combustion of carbon in fuels. This is usually the result of an oxygen deficiency at lower temperatures. Carbon monoxide displaces oxygen in the bloodstream, so it represents an asphyxiation hazard. Carbon monoxide does not contribute to smog.

Generation of carbon monoxide can be minimized by furnace monitoring and control. For industrial sources, the American Boiler Manufacturers Association (ABMA) recommends limiting carbon monoxide to 400 ppm (corrected to 3% O_2) in oil- and gas-fired industrial boilers. This value can usually be met with reasonable ease. Local ordinances may be more limiting, however.

Most carbon monoxide released in highly populated areas comes from vehicles. Vehicular traffic may cause the CO concentration to exceed regulatory limits. For this reason, *oxygenated fuels* are required to be sold in those areas during certain parts of the year. Oxygenated gasoline has a minimum oxygen content of approximately 2.0%. Oxygen is increased in gasoline with additives such as ethanol (ethyl alcohol) or methyl tertiary butyl ether (MTBE).

Minimization of carbon monoxide is compromised by efforts to minimize nitrogen oxides. Control of these pollutants is inversely related.

16. CHLOROFLUOROCARBONS

Most atmospheric oxygen is in the form of two-atom molecules, O_2. However, there is a thin layer in the stratosphere about 12 miles up where *ozone* molecules, O_3, are found in large quantities. Ozone filters out ultraviolet radiation that damages crops and causes skin cancer.

Chlorofluorocarbons (i.e., chlorinated fluorocarbons, such as Freon™) contribute to the deterioration of the Earth's ozone layer. Ozone in the atmosphere is depleted in a complex process involving pollutants, wind patterns, and atmospheric ice. As chlorofluorocarbon molecules rise through the atmosphere, solar energy breaks the chlorine free. The chlorine molecules attach

[10] Industrial exposure is regulated by the U.S. Occupational Safety and Health Administration (OSHA).

themselves to ozone molecules, and the new structure eventually decomposes into chlorine oxide and normal oxygen, O_2. The depletion process is particularly pronounced in the Antarctic because that continent's dry, cold air is filled with ice crystals on whose surfaces the chlorine and ozone can combine. Also, the prevailing winter wind isolates and concentrates the chlorofluorocarbons.

Table 32.3 *Typical Replacement Compounds for Chlorofluorocarbons*

designation	applications
HCFC 22	low- and medium-temperature refrigerant; blowing agent; propellant
HCFC 123	replacement for CFC-11; industrial chillers and applications where potential for exposure is low; somewhat toxic; blowing agent; replacement for perchloroethylene (dry cleaning fluid)
HCFC 124	industrial chillers; blowing agent
HFC 134a	replacement for CFC-12; medium-temperature refrigeration systems; centrifugal and reciprocating chillers; propellant
HCFC 141b	replacement for CFC-11 as a blowing agent; solvent
HCFC 142b	replacement for CFC-12 as a blowing agent; propellant
IPC (isopropyl chloride)	replacement for CFC-11 as a blowing agent

The depletion is not limited to the Antarctic, but occurs throughout the northern hemisphere, including virtually all of the United States. At various points during the year in the Northern Hemisphere, the ozone deficit is as much as 6%.

The 1987 Montreal Protocol (conference) resulted in an international agreement to phase out world-wide production of chemical compounds that have ozone-depletion characteristics.

The Clean Air Act (Title VI) follows the Montreal Protocol and prohibits production of chlorofluorocarbons (and Halon) in the United States. The 1990 Clean Air Act required that class I chemicals, including chlorofluorocarbons (CFCs), Halons, and carbon tetrachloride, be phased out by the year 2000. The fumigant methyl chloride, also a class I chemical, was given a phase-out deadline of 2002. The 1990 Clean Air Act required that class II chemicals, including hydrochlorofluorocarbons (HCFCs), be phased out by the year 2030.

Special allowances are made for aviation safety, national security, and fire suppression and explosion prevention if safe or effective substitutes are not available for those purposes. Excise taxes are used as interim disincentives for those who produce the compounds. Large reserves and recycling, however, probably ensure that chlorofluorocarbons and Halons will be in use for many years after the deadlines have passes.

Possible replacements for chlorofluorocarbons (CFCs) include hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs), both of which are environmentally more benign than CFCs, and blends of HCFCs and HFCs. The additional hydrogen atoms in the molecules make them less stable, allowing nearly all chlorine to dissipate in the lower atmosphere before reaching the ozone layer. The lifetime of HCFC molecules is 2 to 25 years, compared with 100 years or longer for CFCs. The net result is that HCFCs have only 2 to 10% of the ozone-depletion ability of CFCs. HFCs have no chlorine and thus cannot deplete the ozone layer.

Most chemicals intended to replace CFCs still have chlorine, but at reduced levels. Additional studies are determining if HCFCs and HFCs accumulate in the atmosphere, how they decompose, and whether any by-products could damage the environment.

17. COOLING TOWER BLOWDOWN

State-of-the art reuse programs in *cooling towers* (CTs) may recirculate water 15 to 20 times before it is removed through blowdown. Pollutants such as metals, herbicides, and pesticides originally in the makeup water are concentrated to five or six times their incoming concentrations. Most CTs are constructed with copper alloy condenser tubes, so the recirculated water becomes contaminated with copper ions as well. CT water also usually contains chlorine compounds or other biocides added to inhibit biofouling. Ideally, no water should leave the plant (i.e., a *zero-discharge facility*). If discharged, CT blowdown must be treated prior to disposal.

18. CONDENSER COOLING WATER

Approximately half of the electrical generation plants in the United States use *once-through (OT) cooling water*. The discharged cooling water may be a chemical or thermal pollutant. Since fouling in the main steam condenser significantly reduces performance, water can be treated by the intermittent addition of chlorine, chlorine dioxide, bromine, or ozone, and these chemicals may be present in residual form. *Total residual chlorine* (TRC) is regulated. Methods of chlorine control include *targeted chlorination* (the frequent application of small amounts of chlorine where needed) and *dechlorination.*

19. DIOXINS

Dioxins are a family of chlorinated dibenzo-*p*-dioxins (CDDs). The term *dioxin*, however, is commonly used to refer to the specific congener 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Primary sources of dioxin include herbicides containing 2,4-T, 2,4,5-trichlorophenol, and hexachlorophene. Other potential sources include incinerated municipal and industrial waste, leaded gasoline exhaust, chlorinated chemical wastes, incinerated polychlorinated biphenyls (PCBs), and any combustion in the presence of chlorine.

The exact mechanism of dioxin formation during incineration is complex but probably requires free chlorine (in the form of HCl vapor), heavy metal concentrations (often found in the ash), and a critical temperature window of 570 to 840°F (300 to 450°C). Dioxins in incinerators probably form near waste heat boilers, which operate in this temperature range.

Dioxin destruction is difficult because it is a large organic molecule with a high boiling point. Most destruction methods rely on high temperature since temperatures of 1550°F (850°C) denature the dioxins. Other methods include physical immobilization (i.e., vitrification), dehalogenation, oxidation, and catalytic cracking using catalysts such as platinum.

Dioxins liberated during the combustion of municipal solid waste (MSW) and refuse-derived fuel (RDF) can be controlled by the proper design and operation of the furnace combustion system. Once formed, they can be removed by end-of-pipe processes, including activated charcoal (AC) injection. Success has also been reported using the vanadium oxide catalyst used for NOx removal.

20. DUST, GENERAL

Dust or *fugitive dust* is any solid particulate matter (PM) that becomes airborne, with the exception of PM emitted from the exhaust stack of a combustion process. Nonhazardous fugitive dusts are commonly generated when a material (e.g., coal) is unloaded from trucks and railcars. Dusts are also generated by manufacturing, construction, earth-moving, sand blasting, demolition, and vehicle movement.

Dusts pose three types of hazards. (a) Inhalation of airborne dust or vapors, particularly those that carry hazardous compounds, is the major concern. Even without toxic compounds, odors can be objectionable. Dusts are easily observed and can cover cars and other objects left outside. (b) Dusts can transport hazardous materials, contaminating the environment far from the original source. (c) In closed environments, even nontoxic dusts can represent an explosion hazard.

Dust emission reduction from *spot sources* (e.g., manufacturing processes such as grinders) is accomplished by *inertial separators* such as cyclone separators. Potential dust sources (e.g., truck loads and loose piles) can be covered, and dust generation can be reduced by spraying water mixed with other compounds.

There are three mechanisms of dust control by spraying. (a) In *particle capture* (as occurs in a spray curtain at a railcar unloading station), suspended particles are knocked down, wetted, and captured by liquid droplets. (b) In *bulk agglomeration* (as when a material being carried on a screw conveyor is sprayed), the moisture keeps the dust with the material being transported. (c) Spraying roads and coal piles to inhibit wind-blown dust is an example of *surface stabilization.*

Wetting agents are *surfactant* formulations added to water to improve water's ability to wet and agglomerate fine particles.[11] The resulting solution can be applied as liquid spray or as a foam.[12] *Humectant binders* (e.g., magnesium chloride and calcium chloride) and adhesive binders (e.g., waste oil) may also be added to the mixture to make the dust adhere to the contact surface if other water-based methods are ineffective.[13]

Surface stabilization of materials stored outside and exposed to wind, rain, freeze-thaw cycles, and ultraviolet radiation is enhanced by the addition of *crusting agents.*

21. DUST, COAL

Clean coals, western low-sulfur coal, eastern low-sulfur coal, eastern high-sulfur coal, low-rank lignite coal, and varieties in between have their own peculiar handling characteristics.[14] *Dry ultra-fine coal* (DUC) and coal slurries have their own special needs.

Western coals have a lower sulfur content, but because they are easily fractured, they generate more dust. Western coals also pose higher fire and explosion hazards than eastern coals. Water misting or foam must be applied to coal cars, storage piles, and conveyer transfer points. Adequate ventilation in storage silos and bunkers is also required, with the added benefit of reducing methane accumulation.

DUC is as fine as talcum (10 μm with less than 10% moisture).[15] It must be containerized for transport, because traditional railcars are not sufficiently airtight. Also, since the minimum oxygen content for combustion is 14 to 15%, DUC should be maintained in a pressurized, oxygen-depleted environment until used. Pneumatic flow systems are used to transport DUC through the combustion plant.

[11] A *surface-acting agent (surfactant)* is a soluble compound that reduces a liquid's surface tension or reduces the interfacial tension between a liquid and a solid.

[12] Foam is an increasingly popular means of reducing the potential for explosions in secondary coal crushers.

[13] A *humectant* is a substance that absorbs or retains moisture.

[14] A valuable resource for this subject is NFPA 850, *Fire Protection for Fossil Fueled Steam and Combustion Turbine Electrical Generating Plants,* National Fire Protection Association, Quincy, MA.

[15] A μm is a *micrometer*, 10^{-6} m, and is commonly referred to as a *micron.*

22. FUGITIVE EMISSIONS

Equipment leaks from plant equipment are known as *fugitive emissions* (FEs). Leaks from pump and valve seals are common sources, though compressors, pressure-relief devices, connectors, sampling systems, closed vents, and storage vessels are also potential sources. FEs are reduced administratively by *leak detection and repair programs* (LDARs).

Common causes of fugitive emissions are (a) equipment in poor condition, (b) off-design pump operation, (c) inadequate seal characteristics, and (d) inadequate boiling-point margin in the seal chamber. Other pump/shaft/seal problems that can increase emissions include improper seal-face material, excessive seal-face loading and seal-face deflections, and improper pressure balance ratio.

Inadequate *boiling-point margin* (BPM) results in poor seal performance and face damage. BPM is the difference between the seal chamber temperature and the initial boiling point temperature of the pumped product at the seal chamber pressure. When seals operate close to the BPM, seal-generated heat can cause the pumped product between the seal faces to flash and the seal to run dry. A minimum BPM of 15°F (9°C) or a 25 psig (172 kPa) pressure margin is recommended to avoid flashing. Even greater margins will result in longer seal life and reduced emissions.

23. GASOLINE-RELATED POLLUTION

Gasoline-related pollution is primarily in the form of unburned hydrocarbons, nitrogen oxides, lead, and carbon monoxide. (The requirement for lead-free gasoline has severely curtailed gasoline-related lead pollution.) Though a small reduction in gasoline-related pollution can be achieved by blending detergents into gasoline, reformulation is required for significant improvements. Table 32.4 lists typical characteristics for traditional and reformulated gasolines.

Table 32.4 *Typical Gasoline Characteristics*

fuel parameter	traditional	reformulated
sulfur	150 ppmw[a]	40 ppmw
benzene	2% by vol	1% by vol
olefins	9.9% by vol	4% by vol
aromatic hydrocarbons	32% by vol	25% by vol
oxygen	0	1.8 to 2.2% by wt
T90	330°F (166°C)	300°F (149°C)
T50	220°F (104°C)	210°F (99°C)
RVP	8.5 psig (59 kPa)	7 psig (48 kPa)

[a]ppmw = parts per million by weight

The potential for smog formation can be reduced by reformulating gasoline and/or reducing the summer *Reid vapor pressure* (RVP) of the blend. Regulatory requirements to reduce the RVP can be met, in the short run, by using less butane in the gasoline. However, reformulating to remove pentanes is required when the RVP is required to achieve 7 psig (48 kPa) or below. Sulfur content can be reduced by pretreating the refinery feed in hydrodesulfurization (HDS) units. Heavier gasoline components must be removed to lower the 50% and 90% *distillation temperatures* (T50 and T90).

24. GLOBAL WARMING

The *global warming* hypothesis is that increased levels of atmospheric carbon dioxide, CO_2, from the combustion of carbon-rich fossil fuels and other *greenhouse gases* (e.g., water vapor, methane, nitrous oxide, and chlorofluorocarbons) trap an increasing amount of solar radiation in a *greenhouse effect*, gradually increasing the Earth's temperature. It is claimed that the most recent cycle of increases in carbon dioxide began with the industrial revolution.

Recent studies have shown that atmospheric carbon dioxide is increasing at the rate of about 1% per year. (For example, in one year carbon dioxide might increase from 350 ppmv to 354 ppmv. By comparison, oxygen is approximately 209,500 ppmv.) There has also been a 100% increase in atmospheric methane since the beginning of the industrial revolution. According to some researchers, there has been a corresponding global temperature increase of approximately 0.9°F (0.5°C) since the year 1890.[16]

In addition to a temperature increase, other evidence cited by supporters of the global warming hypothesis are several record-breaking hot summers, widespread aberrations in the traditional seasonal weather patterns (e.g., hurricane-like storms in England), and a 4 to 12 in (10 to 30 cm) rise in sea level over the last century.[17]

The global warming hypothesis is disputed by many scientists and has not been proved to be an absolute truth. Arguments against the hypothesis center around the fact that manufactured carbon dioxide is a small fraction of what is naturally released (e.g., by wetlands, in rain forest fires, and during volcanic eruptions). It is argued that, in the face of such massive contributors, and since the Earth's temperature has remained essentially constant for millenia, the Earth already possesses some built-in mechanism, currently not perfectly understood, that reduces the Earth's temperature swings.

The environmentalists' claim that there will be a temperature increase of 3 to 9°F (1.7 to 5°C) by the year 2100 and that this increase will be catastrophic is also

[16]Other researchers can detect no discernible upward trend, and some offer a counter-argument. Based on the retreat of the northern-most lines capable of growing oranges since 1850, some believe that the weather is generally becoming colder, not hotter.

[17]The rise in the level of the oceans is disputed.

disputed by many scientists. On the contrary, most scientists agree that the deprivation and human suffering that would result from a reduction or cessation in the burning of fossil fuels will be significantly higher than the effects of a slightly increased temperature.

Regardless of the validity of the global warming hypothesis, some major power generation industries have adopted goals of reducing carbon dioxide emissions. However, efforts to reduce carbon dioxide emissions by converting fossil fuel from one form to another are questioned by many engineers. Natural gas produces the least amount of carbon dioxide of any fossil fuel. Therefore, conversion of coal to a gas or liquid fuel in order to lower the carbon-to-hydrogen ratio would appear to lessen carbon dioxide emissions at the point of final use. However, the conversion processes consume energy derived from carbon-containing fuel. This additional consumption, taken over all sites, results in a net increase in carbon dioxide emission of 10 to 200%, depending on the process.

The use of ethanol as an alternative for gasoline is also problematic. Manufacturing processes that produce ethanol give off (at least) twice as much carbon dioxide as the gasoline being replaced produces during combustion.

Most synthetic fuels are intrinsically less efficient (based on their actual heating values compared with those theoretically obtainable from the fuels' components in elemental form). This results in an increase in the amount of fuel consumed. Thus, fossil fuels should be used primarily in their raw forms until cleaner sources of energy are available.

25. LEAD

Lead, even in low concentrations, is toxic. Inhaled lead accumulates in the blood, bones, and vital organs. It can produce stomach cramps, fatigue, aches, and nausea. It causes irreparable damage to the brain, particularly in young and unborn children, and high blood pressure in adults. At high concentrations, lead damages the nervous system and can be fatal.

Lead was outlawed in paint in the late 1970s.[18] Lead has also been removed from most gasoline blends. Lead continues to be used in large quantities in automobile batteries and plating and metal-finishing operations. However, these manufacturing operations are tightly regulated. Lead enters the atmosphere during the combustion of fossil fuels and the smelting of sulfide ore. Lead enters lakes and streams primarily from acid mine drainage.

For lead in industrial and municipal wastewater, current remediation methods include pH adjustment with lime or alkali hydroxides, coagulation-sedimentation, reverse osmosis, and zeolite ion exchange.

[18]Workers can be exposed to lead if they strip away lead-based paint, demolish old buildings, or weld or cut metals that have been coated with lead-based paint.

26. NITROGEN OXIDES

Nitrogen oxides (NOx) are one of the primary causes of smog formation.[19] NOx from the combustion of coal is primarily *nitric oxide* (NO) with small quantities of *nitrogen dioxide* (NO_2).[20] NO_2 can be a primary or a secondary pollutant. Although some NO_2 is emitted directly from combustion sources, it is also produced from the oxidation of nitric oxide, NO, in the atmosphere.

NOx is produced in two ways: (a) *thermal NOx* produced at high temperatures from free nitrogen and oxygen, and (b) *fuel NOx* (or *fuel-bound NOx*) formed from the decomposition/combustion of fuel-bound nitrogen.[21] When natural gas and light distillate oil are burned, almost all of the NOx produced is thermal. Residual fuel oil, however, can have a nitrogen content as high as 0.3%, and 50 to 60% of this can be converted to NOx. Coal has an even higher nitrogen content.[22]

Thermal NOx is usually produced in small (but significant) quantities when excess oxygen is present at the highest temperature point in a furnace, such that nitrogen (N_2) can dissociate.[23] Dissociation of N_2 and O_2 is negligible, and little or no thermal NOx is produced below approximately 3000°F (1650°C).

Formation of thermal NOx is approximately exponential with temperature. For this reason, many NOx-reduction techniques attempt to reduce the *peak flame temperature* (PFT). NOx formation can be reduced also by injecting urea or ammonia reagents directly into the furnace.[24] The relationship between NOx production and excess oxygen is somewhat inconclusive, but NOx production appears to vary directly with the square root of the oxygen concentration.

In existing plants, retrofit NOx-reduction techniques include fuel-rich combustion (i.e., staged air burners), flue gas recirculation, changing to a low-nitrogen fuel, reduced air preheat, installing low-NOx burners, and

[19]In Los Angeles County, approximately 75% of the NOx is produced by vehicles, with the remainder being produced by combustion operations, such as boilers and heaters.

[20]Other oxides are produced in insignificant amounts. These include *nitrous oxide* (N_2O), N_2O_4, N_2O_5, and NO_3, all of which are eventually oxidized to (and reported as) NO_2.

[21]Some engineers further divide the production of fuel-bound NOx into low- and high-temperature processes and declare a third fuel-related NOx-production method known as *prompt-NOx*. Prompt-NOx is the generation of the first 15 to 20 ppm of NOx from partial combustion of the fuel at lower temperatures.

[22]In order of increasing fuel-bound NOx production potential, common boiler fuels are: methanol, ethanol, natural gas, propane, butane, ultralow-nitrogen fuel oil, fuel oil No. 2, fuel oil No. 6, and coal.

[23]The *mean residence time* at the high temperature points of the combustion gases is also an important parameter. At temperatures below 2500°F (1370°C), several minutes of exposure may be required to generate any significant quantities of NOx. At temperatures above 3000°F (1650°C), dissociation can occur in less than a second. At the highest temperatures—3600°F (1980°C) and above—dissociation takes less than a tenth of a second.

[24]*Urea* (NH_2CONH_2), also known as *carbamide urea*, is a water-soluble organic compound prepared from ammonia. Urea has significant biological and industrial usefulness.

using overfire air.[25] Low-NOx burners using controlled flow/split flame or internal fuel staging technology are essentially direct replacement (i.e., "plug in") units, differing from the original burners primarily in nozzle configuration. However, some fuel supply and air modifications may also be needed. Use of overfire air requires windbox modifications and separate ducts.

Lime spray-dryer scrubbers of the type found in electrical generating plants do not remove all of the NOx. Further reduction requires that the remaining NOx be destroyed. Reburn, selective catalytic reduction (SCR), and selective noncatalytic methods are required.

Scrubbing, incineration, and other end-of-pipe methods typically have been used to reduce NOx emissions from stationary sources such as gas turbine-generators, although these methods are unwieldy for the smallest units. Water/steam injection, catalytic combustion, and *selective catalytic reduction* (SCR) are particularly suited for gas-turbine and combined-cycle installations. SCR is also effective in NOx reduction in all heater and boiler applications.

27. ODORS

Odors of unregulated substances can be eliminated at their source, contained by sealing and covering, diluted to unnoticeable levels with clean air, or removed by simple water washing, chemical scrubbing (using acid, alkali, or sodium hypochlorite), bioremediation, and activated carbon adsorption.

28. OIL SPILLS IN NAVIGABLE WATERS

Intentional and accidental releases of oil in navigable waters are prohibited. Deleterious effects of such spills include large-scale biological (i.e., sea life and wildlife) damage and destruction of scenic and recreational sites. Long-term toxicity can be harmful for microorganisms that normally live in the sediment.[26]

29. OZONE

Ground-level ozone is a secondary pollutant. Ozone is not usually emitted directly, but is formed from hydrocarbons and nitrogen oxides (NO and NO_2) in the presence of sunlight. *Oxidants* are byproducts of reactions between combustion products. Nitrogen oxides react with other organic substances (e.g., hydrocarbons) to form the oxidants ozone and peroxyacyl nitrates (PAN) in complex *photochemical reactions.* Ozone and PAN are usually considered to be the major components of smog.[27] (See also Smog.)

[25]Air is injected into the furnace at high velocity over the combustion bed to create turbulence and to provide oxygen.

[26]This has given rise to a new *sediment testing technology.*

[27]The term *oxidant* sometimes is used to mean the original emission products of NOx and hydrocarbons.

30. PARTICULATE MATTER

Particulate matter (PM), also known as *aerosols*, is defined as all particles that are emitted by a combustion source. Particulate matter with aerodynamic diameters of less than or equal to a nominal 10 μm is known as *PM-10.* Particulate matter is generally inorganic in nature. It can be categorized into metals (or heavy metals), acids, bases, salts, and nonmetallic inorganics.

Metallic inorganic PM from incinerators is controlled with baghouses or electrostatic precipitators (ESPs), while nonmetallic inorganics are removed by scrubbing (wet absorption). Flue gas PM, such as flyash and lime particles from desulfurization processes, can be removed by fabric baghouses and electrostatic precipitators. These processes must be used with other processes that remove NOx and SO_2.

High temperatures cause the average flue gas particle to decrease in size toward or below 10 μm. With incineration, emission of trace metals into the atmosphere increases significantly. Because of this, incinerators should not operate above 1650°F (900°C.)[28]

31. PCBs

Polychlorinated biphenyls (PCBs) are organic compounds (i.e., *chlorinated organics*) manufactured in oily liquid and solid forms through the late 1970s, and subsequently prohibited. PCBs are carcinogenic and can cause skin lesions and reproductive problems. PCBs build up, rather than dissipate, in the food chain, accumulating in fatty tissues. Most PCBs were used as dielectric and insulating liquids in large electrical transformers and capacitors, and in ballasts for fluorescent lights (which contain capacitors). PCBs were also used as heat transfer and hydraulic fluids, as dye carriers in carbonless copy paper, and as plasticizers in paints, adhesives, and caulking compounds.

Incineration of PCB liquids and PCB-contaminated materials (usually soil) has long been used as an effective mediation technique. However, PCB-contaminated soil apparently can be effectively treated in situ by adding high-calcium flyash or (more expensive) aluminum powder. The reduction mechanism is unclear, but catalysis with an unidentified catalyst is most likely. The destruction of PCB is total. (The addition of quicklime alone has not been supported as a treatment method.)

Specialized PCB processes targeted at cleaning PCB from spent oil are also available. Final PCB concentrations are below detectable levels, and the cleaned oil can be recycled or used as fuel.

32. PLASTICS

Plastics, of which there are six main chemical polymers, generally do not degrade once disposed of, and

[28]The upper temperature limit for biosolids (sewage sludge) incineration may be regulated.

are therefore considered a disposal issue. Disposal is not a problem per se, however, since plastics are lightweight, inert, and do not harm the environment when discarded.

A distinction is made between *biodegrading* and *recycling*. Most plastics, such as the polyethylene bags used to protect pressed shirts from the dry cleaners and to mail some magazines, are not biodegradable but are recyclable. Also, all plastics can be burned for their fuel value.

The collection and sorting problems often render low-volume plastic recycling efforts uneconomical. Complicating the drive toward recycling is the fact that many of the six different types cannot be distinguished visually, and they cannot be recycled successfully when intermixed. Also, some plastic products consist of layers of different polymers that cannot be separated mechanically.

Table 32.5 *Polymers*

polymer	common use
low-density polyethylene (LDPE)	grocery bags; food wrap
high-density polyethylene (HDPE)	detergent; milk bottles; oil containers; toys
polyethylene terephthalate (PET)	clear beverage containers
polypropylene (PP)	labels; bottles; housewares;
polyvinyl chloride (PVC)	clear bottles
polystyrene (PS)	styrofoam cups; "clam shell" food containers

Sorting in low-volume applications is performed visually and manually. Commercial high-volume methods include hydrocycloning, flotation with flocculation (for all polymers), x-ray fluorescence (primarily for PVC detection), and near-infrared spectroscopy (primarily for separating PVC, PET, PP, PE, and PS). Mass spectroscopy is also promising, but has yet to be commercialized.

Unsorted plastics can be melted and reformed into some low-value products. This operation is known as *downcycling*, since each successful cycle further degrades the material. This method is suitable only for a small fraction of the overall recyclable plastic.

Other operations that can reuse the compounds found in plastic products are hydrogenation, pyrolysis, and gasification. *Hydrogenation* is the conversion of mixed plastic scrap to "syncrude," synthetic crude oil, in a high-temperature (i.e., 750 to 880°F (400 to 470°C)), high-pressure (i.e., 2200 to 4400 psig (15 to 30 MPa)), hydrogen-rich atmosphere. Since the end product is a crude oil substitute, hydrogenation operations must be integrated into refinery or petrochemical operations.

Gasification and pyrolysis are stand-alone operations that do not require integration with a refinery. *Pyrolysis* takes place in a fluidized bed between 750°F and 1475°F (400°C and 800°C). Cracked polymer gas or other inert gas fluidizes the sand bed, which promotes good mixing and heat transfer, resulting in liquid and gaseous petroleum products.

Gasification operates at higher temperatures, 1650 to 3600°F (900 to 2000°C), and lower pressures, around 870 psig (6 MPa). The waste stream is pyrolyzed at lower temperatures before being processed by the gasifier. The gas can be used on-site to generate steam. Gasification has the added advantage of being able to treat the entire municipal solid waste stream, avoiding the need for sorting plastics.

The development and use of a biodegradable plastic is an alternative to recycling. Original research in degradable plastics focused on nondegradable polymers mixed with small amounts of materials that reacted with sunlight and soil microbes. Such products, however, were criticized by environmentalists as being waste that broke down into smaller nondegradable pieces. Polymers that are derived from agricultural sources, rather than from petroleum, are now being investigated in the search for totally biodegradable plastics.

Success has been reported with polymers based on blackstrap molasses (a sugar production waste residue) and potato or corn starches. Another promising degradable polymer is polyhydroxybutyrate-valerate (PBHV), derived from the bacterium *alcaligenes eutrophus*. The bacteria, when deprived of phosphorus, feed on organic acids and sugars, converting more than 80% of their body mass into PBHV.

Some engineers point out that biodegrading is not even a desirable characteristic for plastics and that being nonbiodegradable is not harmful. Biodegrading converts materials (such as the paper bags often preferred over plastic bags) to water and carbon dioxide, contributing to the greenhouse effect without even receiving the energy benefit of incineration. Biodegrading of most substances also results in gases and leachates that can be more harmful to the environment than the original substance. In a landfill, biodegrading serves no useful purpose, since the space occupied by the degraded plastic does not create additional useful space (volume).

33. RADON

Radon gas is a radioactive gas produced from the natural decay of radium within the rocks beneath a building.[29] Radon accumulates in unventilated areas (e.g., basements), in stagnant water, and in air pockets formed when the ground settles beneath building slabs. Radon also can be brought into the home by radon-saturated

[29]Radon also can be generated in concrete made from slag derived from uranium mines. Such mines are primarily located in Colorado, Florida, Oregon, and South Dakota.

well water used in baths and showers. The maximum acceptable concentration is approximately 3 pCi/L.

Radon mitigation methods include (a) pressurizing to prevent the infiltration of radon, (b) installing of depressurization systems to intercept radon below grade and vent it safely, (c) removing radon-producing soil, and (d) abandoning radon-producing sites.

34. RAINWATER RUNOFF

Rainwater percolating through piles of coal, flyash, mine tailings, and other stored substances can absorb toxic compounds and eventually make its way into the earth, possibly contaminating soil and underground aquifers.

35. RAINWATER RUNOFF FROM HIGHWAYS

The *first flush* of a storm is generally considered to be the first half-inch of storm runoff or the runoff from the first 15 min of the storm. Along highways and other paved transportation corridors, the first flush contains potent pollutants such as petroleum products, asbestos fibers from brake pads, tire rubber, and fine metal dust from wearing parts. Under the National Pollutant Discharge Elimination System (NPDES), stormwater runoff in newly developed watersheds must be cleaned before it reaches existing drainage facilities, and runoff must be maintained at or below the present undeveloped runoff rate.

A good stormwater system design generally contains two separate basins or a single basin with two discrete compartments. The function of one compartment is water quality control, and the function of the other is peak runoff control.

The *water quality compartment* (WQC) should normally have sufficient volume and discharge rates to provide a minimum of 1 hour of detention time for 90 to 100% of the first flush volume. "Treatment" in the WQC consists of sedimentation of suspended solids and evaporation of volatiles. A removal goal of 75% of the suspended solids is reasonable in all but the most environmentally sensitive areas.

In environmentally sensitive areas, a filter berm of sand, a sand chamber, or a sand filter bed can further clarify the discharge from the WQC.

After the WQC becomes full from the first flush, subsequent runoff will be diverted to the *peak-discharge compartment* (PDC). This is done by designing a junction structure with an inlet for the incoming runoff and separate outlets from each compartment. If the elevation of the WQC outlet is lower than the inlet to the PDF, the first flush will be retained in the WQC.

Sediment from the WQC chamber and any filters should be removed every 1 to 3 years, or as required. The sediment must be properly handled, as it may be considered to be hazardous waste under the EPA's "mixture" and "derived-from" rules and its "contained-in" policy.

When designing chambers and filters, sizing should accommodate the first flush of a 100-year storm. The top of the berm between the WQC and PDC should include a minimum of 1 ft (0.3 m) of freeboard. In all cases, an emergency overflow weir should allow a storm greater than the design storm to discharge into the PDC or receiving water course.

Minimum chamber and berm width is approximately 8 ft (2.4 m). Optimum water depth in each chamber is approximately 2 to 5 ft (0.6 to 1.5 m). Each compartment can be sized by calculating the divided flows and staging each compartment. The outlet from the WQC should be sufficient to empty the compartment in approximately 24 to 28 hours after a 25-year storm.

A *filter berm* is essentially a sand layer between the WQC and the receiving chamber that filters water as it flows between the two compartments. The filter should be constructed as a layer of sand placed on geosynthetic fabric, protected with another sheet of geosynthetic fabric, and covered with coarse gravel, another geosynthetic cover, and finally a layer of medium stone. The sand, gravel, and stone layers should all have a minimum thickness of 1 ft (0.3 m). The rate of permeability is controlled by the sand size and front-of-fill material. Permeability calculations should assume that 50% of the filter fabric is clogged.

A *filter chamber* consists of a concrete structure with a removable filter pack. The filter pack consists of geosynthetic fabric wrapped around a plastic frame (core) that can be removed for backwashing and maintenance. The filter is supported on a metal screen mounted in the concrete chamber. The outlet of the chamber should be located at least 1 ft (0.3 m) behind the filter pack. The opening's size will determine the discharge rate through the filter, which should be designed as less than 2 ft/sec (60 cm/s) assuming that 50% of the filter area is clogged.

A *sand filter bed* is similar to the filter beds used for tertiary sewage treatment. The sand filter consists of a series of 4 in (100 mm) perforated PVC pipes in a gravel bed. The gravel bed is covered by geotextile fabric and 8 in (200 mm) of fine-to-medium sand. The perforated underdrains lead to the outlet channel or chamber.

36. SMOG

Photochemical smog (usually, just *smog*) consists of ground-level ozone and peroxyacyl nitrates (PAN). Smog is produced by the sunlight-induced reaction of ozone *precursors*, primarily nitrogen dioxide (NOx), hydrocarbons, and volatile organic compounds (VOCs). NOx and hydrocarbons are emitted by combustion sources such as automobiles, refineries, and industrial boilers. VOCs are emitted by manufacturing processes, dry cleaners, gasoline stations, print shops, painting operations, and municipal wastewater treatment plants. (See also Ozone.)

37. SMOKE

Smoke results from incomplete combustion and indicates unacceptable combustion conditions. In addition to being a nuisance problem, smoke contributes to air pollution and reduced visibility. Smoke generation can be minimized by proper furnace monitoring and control.

Opacity can be measured by a variety of informal and formal methods, including transmissometers mounted on the stack. The sum of the *opacity* (the fraction of light blocked) and the *transmittance* (the fraction of light transmitted) is 1.0.

Optical density is calculated from Eq. 32.1. The *smoke spot number* (SSN) can also be used to quantify smoke levels.

$$\text{optical density} = \log_{10}\left(\frac{1}{1 - \text{opacity}}\right) \qquad 32.1$$

Visible moisture plumes with opacities of 40% are common at large steam-generators even when there are no unburned hydrocarbons emitted. High-sulfur fuels and the presence of ammonium chloride (a byproduct of some ammonia-injection processes) seem to increase formation of visible plumes. Moisture plumes from saturated gas streams can be avoided by reheating prior to discharge to the atmosphere.

38. SPILLS, HAZARDOUS

Contamination by a hazardous material can occur accidentally (e.g., a spill) or intentionally (e.g., a previously used chemical-holding lagoon). Soil that has been contaminated with hazardous materials from spills or leaks from *underground storage tanks* (commonly known as *UST wastes*) is itself a hazardous waste.

The type of waste determines what laws are applicable, what permits are required, and what remediation methods are used.[30] With contaminated soil, spilled substances can be (a) solid and nonhazardous or (b) nonhazardous liquid petroleum products (e.g., "UST nonhazardous"), and Resource Conservation and Recovery Act- (RCRA-) listed (c) hazardous substances, and (d) toxic substances.

Cleaning up a hazardous waste requires removing the waste from whatever air, soil, and water (lakes, rivers, and oceans) that have been contaminated. The term *remediation* is sometimes used to mean the corrective steps taken to return the environment to its original condition. *Stabilization* refers to the act of reducing the waste concentrations to lower levels so that the waste can be transported, stored, or landfilled.

Remediation methods are classified as available or innovative. *Available methods* can be implemented immediately without being further tested. *Innovative methods* are new, unproven methods in various stages of study.

[30]Permits must be obtained from the U.S. Environmental Protection Agency (EPA) whenever hazardous wastes (including hazardous-waste contaminated soil) are incinerated.

The remediation method used depends on the waste type. The two most common available methods are incineration and landfilling after stabilization.[31] Incineration can occur in rotary kilns, injection incinerators, infrared incineration, and fluidized-bed combustors. Landfilling requires the contaminated soil to be stabilized chemically or by other means prior to disposal. Innovative technologies for general VOC-contaminated soil include vacuum extraction, bioremediation, thermal desorption, and soil washing. Innovative methods for dioxin removal include oxygen-enriched incineration, plasma incineration, chemical dehalogenation, and ultraviolet radiation.

39. SULFUR OXIDES

Sulfur oxides (SOx), consisting of *sulfur dioxide* (SO_2) and *sulfur trioxide* (SO_3), are the primary cause of acid rain. *Sulfurous acid* (H_2SO_3) and sulfuric acid (H_2SO_4) are produced when oxides of sulfur react with moisture in the flue gas. Both of these acids are corrosive.

$$SO_2 + H_2O \longrightarrow H_2SO_3 \qquad 32.2$$

$$SO_3 + H_2O \longrightarrow H_2SO_4 \qquad 32.3$$

Fuel switching (*coal substitution/blending* (CS/B)) is the burning of low-sulfur fuel. (Low-sulfur fuels are approximately 0.25 to 0.65% sulfur by weight, compared to high-sulfur coals with 2.4 to 3.5% sulfur.) However, unlike nitrogen oxides, which can be prevented during combustion, formation of sulfur oxides cannot be avoided when low-cost, high-sulfur fuels are burned.

Some air quality regulations regarding SOx production may be met by a combination of options. These options include fuel switching, flue gas scrubbing, derating, and allowance trading. The most economical blend of these options will vary from location to location.

In addition to fuel switching, available technology options for retrofitting existing coal-fired plants include wet scrubbing, dry scrubbing, sorbent injection, repowering with clean coal technology (CCT), and co-firing with natural gas.

40. TIRES

Discarded tires are more than a disposal problem. At 15,000 Btu/lbm (35 MJ/kg), their energy content is 80% of crude oil. Discarded tires are wasted energy resources. While tires can be incinerated, other processes can be used to gasify them to produce clean synthetic gas (i.e., *syngas*). The low-sulfur, hydrogen-rich syngas can be subsequently burned in combined-cycle plants or used as a feedstock for ammonia and methanol production, or the hydrogen can be recovered for separate use.

[31]Other innovative technologies include in situ and ex situ bioremediation, chemical treatment, in situ flushing, in situ vitrification, soil vapor extraction, soil washing, solvent extraction, and thermal desorption.

Tires can also be converted in a nonchemical process into a strong asphalt-rubber pavement. In one process, asphalt binder is mixed with ground tire rubber and held at 375°F (190°C) for 30 to 60 minutes. Pavement is then produced in the normal fashion.

41. VOLATILE INORGANIC COMPOUNDS

Volatile inorganic compounds (VICs) include H_2S, NOx (except N_2O), SO_2, HCl, NH_3, and many other less common compounds.

42. VOLATILE ORGANIC COMPOUNDS

Volatile organic compounds (VOCs) (e.g., benzene, chloroform, formaldehyde, methylene chloride, napthalene, phenol, toluene, and trichloroethylene) are highly soluble in water. (VOCs are listed in Chap. 34.) VOCs that have leaked from storage tanks or have been discharged often end up in groundwater and drinking supplies.

There are a large number of methods for removing VOCs, including incineration, chemical scrubbing with oxidants, water washing, air or steam stripping, activated charcoal adsorption processes, SCR (selective catalytic reduction), and bioremediation. Incineration of VOCs is fast and 99%+ effective, but incineration requires large amounts of fuel and produces NOx. Using SCR with heat recovery after incineration reduces the energy input but adds to the expense.

43. WATER VAPOR

Water vapor emitted from sources is not generally considered to be a pollutant.

33 Disposition of Hazardous Materials

1. General Storage 33-1
2. Storage Tanks 33-1
3. Disposition of Hazardous Wastes 33-2

1. GENERAL STORAGE

Storage of *hazardous materials (hazmats)* is often governed by local building codes in addition to state and federal regulations. Types of construction, maximum floor areas, and building layout may all be restricted.[1]

Good engineering judgment is called for in areas not specifically governed by the building code. Engineering consideration will need to be given to the following aspects of storage facility design: (a) spill containment provisions, (b) chemical resistance of construction and storage materials, (c) likelihood of and resistance to explosions, (d) exiting, (e) ventilation, (f) electrical design, (g) storage method, (h) personnel emergency equipment, (i) security, and (j) spill cleanup provisions.

2. STORAGE TANKS

Underground storage tanks (USTs) have traditionally been used to store bulk chemicals and petroleum products. Fire and explosion risks are low with USTs, but subsurface pollution is common since inspection is limited. Since 1988, the U.S. Environmental Protection Agency (EPA) has required USTs to have secondary containment, corrosion protection, and leak detection. UST operators also must carry insurance in an amount sufficient to clean up a tank failure.

Because of the cost of complying with UST legislation, above-ground storage tanks (ASTs) are becoming more popular. AST strengths and weaknesses are the reverse of USTs: ASTs reduce pollution caused by leaks, but the expected damage due to fire and explosion is greatly increased. Because of this, some local ordinances prohibit all ASTs for petroleum products.[2]

The following factors should be considered when deciding between USTs and ASTs: (a) space available, (b) zoning ordinances, (c) secondary containment, (d) leak detection equipment, (e) operating limitations, and (f) economics.

Most ASTs are constructed of carbon or stainless steel. These provide better structural integrity and fire resistance than fiberglass-reinforced plastic and other composite tanks. Tanks can be either field-erected or factory-fabricated (capacities greater than approximately 50,000 gal (190 kL). Factory-fabricated ASTs are usually designed according to UL-142 (Underwriters Laboratories *Standard for Safety*), which dictates steel type, wall thickness, and characteristics of compartments, bulkheads, and fittings. Most ASTs are not pressurized, but those that are must be designed in accordance with the ASME *Boiler and Pressure Vessel Code*, Section VIII.

NFPA 30 ("Flammable and Combustible Liquids," National Fire Protection Association, Quincy, MA) specifies the minimum separation distances between ASTs, other tanks, structures, and public right-of-ways. The separation is a function of tank type, size, and contents. NFPA 30 also specifies installation, spill control, venting, and testing.

ASTs must be double-walled, concrete-encased, or contained in a dike or vault to prevent leaks and spills, and they must meet fire codes. Dikes should have a capacity in excess (e.g., 110 to 125%) of the tank volume. ASTs (as do USTs) must be equipped with overfill prevention systems. Piping should be above-ground wherever possible. Reasonable protection against vandalism and hunters' bullets is also necessary.[3]

Though it's a good idea, ASTs are not typically required to have leak-detection systems. Methodology for leak detection is evolving, but currently includes vacuum or pressure monitoring, electronic gauging, and optical and sniffing sensors. Double-walled tanks may also be fitted with sensors within the interstitial space.

Operationally, ASTs present special problems. In hot weather, volatile substances vaporize and represent an additional leak hazard. In cold weather, viscous contents may need to be heated (often by steam tracing).

[1]For example, flammable materials stored in rack systems are typically limited to heights of 25 ft (8.3 m).

[2]The American Society of Petroleum Operations Engineers (ASPOE) policy statement states, "Above-ground storage of liquid hydrocarbon motor fuels is inherently less safe than underground storage. Above-ground storage of Class 1 liquids (gasoline) should be prohibited at facilities open to the public."

[3]Approximately 20% of all spills from ASTs result from vandalism.

ASTs are not necessarily less expensive than USTs, but they are generally thought to be so. Additional hidden costs of regulatory compliance, secondary containment, fire protection, and land acquisition must also be considered.

3. DISPOSITION OF HAZARDOUS WASTES

When a hazardous waste is disposed of, it must be taken to a registered *treatment, storage, or disposal facility* (TSDF). The EPA's *land ban* specifically prohibits the disposal of hazardous wastes on land prior to treatment. Incineration at sea is also prohibited. Wastes must be treated to specific maximum concentration limits by specific technology prior to disposal in landfills.

Once treated to specific regulated concentrations, hazardous waste residues can be disposed of by incineration or landfilling, or less frequently, by deep-well injection. All disposal facilities must meet detailed design and operational standards.

1. INTRODUCTION

This chapter discusses (in alphabetical order) the methods and equipment that can be used to reduce or eliminate pollution. Legislation often requires use of the *best available control technology* (BACT—also known as the *best available technology*—BAT) and the *maximum achievable control technology* (MACT), *lowest achievable emission rate* (LAER), and *reasonably available control technology* (RACT) in the design of pollution-prevention systems.

2. ABSORPTION, GAS (GENERAL)

Gas *absorption processes* remove a gaseous substance (the *target substance*) from a gas stream by dissolving it in a liquid solvent.[1] Absorption can be used for flue gas cleanup (FGC) to remove sulfur dioxide, hydrogen sulfide, hydrogen chloride, chlorine, ammonia, nitrogen oxides, and light hydrocarbons. Gas absorption equipment includes packed towers, spray towers and chambers, and venturi absorbers.[2]

3. ABSORPTION, GAS (SPRAY TOWERS)

In a general spray tower or spray chamber (i.e., a *wet scrubber*), liquid and gas flow countercurrently or crosscurrently. The gas moves through a liquid spray that is carried downward by gravity. A mist eliminator removes entrained liquid from the gas flow. The liquid can be recirculated. The removal efficiency is moderate.

Spray towers are characterized by their low pressure drops (typically 1 to 2 iwg[3] (0.25 to 0.5 kPa)) and their liquid-to-gas ratios (typically 20 to 100 gal/1000 ft^3 (3 to 14 L/m^3)). For self-contained units, fan power is also low—approximately 3×10^{-4} kW/ft^3 (0.01 kW/m^3) of gas moved.

Flooding of spray towers is an operational difficulty where the liquid spray is carried up the column by the gas stream. Flooding occurs when the gas stream velocity approaches the *flooding velocity*. To prevent this, the tower diameter is chosen such that the gas velocity is approximately 50 to 75% of the flooding velocity.

Flue gas desulfurization (FGD) wet scrubbers can remove approximately 90 to 95% of the sulfur, with efficiencies of 98% claimed by some installations. Stack effluent leaves at approximately 150°F (65°C) and is saturated (or nearly saturated) with moisture. Dense steam plumes may be present unless the scrubbed stream is reheated.

Collected sludge waste and flyash are removed within the scrubber by purely inertial means. After being dewatered, the sludge is landfilled.[4]

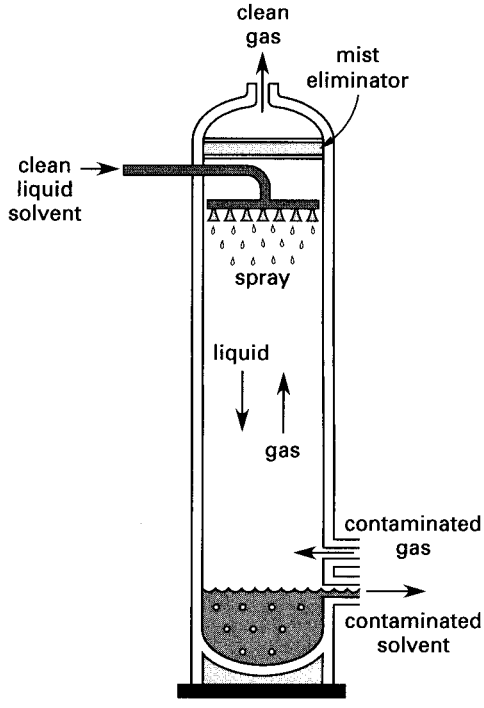

Figure 34.1 *Spray Tower Absorber*

Spray towers, though simple in concept and requiring little energy to operate, are not simple to operate and maintain. Other disadvantages of spray scrubbers include high water usage, generation of wastewater or

[1] Scrubbing, gas absorption, and stripping are distinguished by their target substances, the carrier flow phase, and the directions of flow. *Scrubbing* is the removal of particulate matter from a gas flow by exposing the flow to a liquid or slurry spray. *Gas absorption* is a countercurrent operation for the removal of a target gas from a gas mixture by exposing the mixture to a liquid bath or spray. *Stripping*, also known as *gas desorption* (also a countercurrent operation), is the removal of a dissolved gas or other volatile component from liquid by exposing the liquid to air or steam. Stripping is the reverse operation of gas absorption.

Packed towers can be used for both gas absorption and stripping processes, and the processes look similar. The fundamental difference is that in gas absorption processes, the target substance (i.e., the substance to be removed) is in the gas flow moving up the tower, and in stripping processes, the target substance is in the liquid flow moving down the tower.

[2] Spray and packed towers, though they are capable, are not generally used for desulfurization of furnace or incineration combustion gases, as scrubbers are better suited for this task.

[3] "iwg" is the abbreviation for "inches water gage," also referred to as iwc for "inches water column" and "inches of water."

[4] A typical 500 MW plant burning high-sulfur fuel can produce as much as 10^7 ft^3 (300,000 m^3) of dewatered sludge per year.

sludge, and low efficiency at removing particles smaller than 5 μm. Relative to dry scrubbing, the production of wet sludge and the requirement for a sludge-handling system is the major disadvantage of wet scrubbing.

4. ABSORPTION, GAS (IN PACKED TOWERS)

In a packed tower, clean liquid flows from top to bottom over the tower packing media, usually consisting of synthetic engineered shapes designed to maximize liquid-surface contact area. (See Fig. 34.11.) The contaminated gas flows countercurrently, from bottom to top, although crosscurrent designs also exist. As in spray towers, the liquid can be recirculated, and a mist-eliminator is used.

Pressure drops are in the 1 to 8 iwg (0.25 to 2.0 kPa) range. Typical liquid-to-gas ratios are 10 to 20 gal/1000 ft^3 (1 to 3 L/m^3). Although the pressure drop is greater than in spray towers, the removal efficiency is much higher.

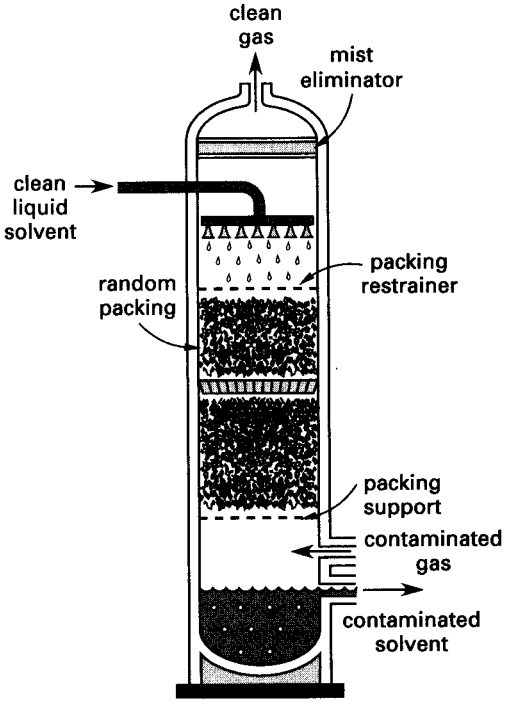

Figure 34.2 *Packed Bed Spray Tower*

5. ADSORPTION (ACTIVATED CARBON)

Granular activated carbon (GAC), also known as *activated carbon* and *activated charcoal* (AC), processes are effective in removing a number of compounds, including volatile organic compounds (VOCs), heavy metals (e.g., lead and mercury), and dioxins.[5] AC is an effective adsorbent[6] for both air and water streams, and a VOC removal efficiency of 99% can be achieved. AC can be manufactured from almost any carbonaceous raw material, but wood, coal, and coconut shell are widely used.

Pollution control processes use AC in both solvent capture-recovery (i.e., recycling) and capture-destruction processes. AC is available in powder and granular form. Granules are preferred for use in recovery systems since the AC can be regenerated when *breakthrough*, also known as *breakpoint*, occurs. This is when the AC has become saturated with the solvent and traces of the solvent begin to appear in the exit air. Until breakthrough, removal efficiency is essentially constant. The *retentivity* of the AC is the ratio of adsorbed solvent mass to carbon mass.

6. ADSORPTION (SOLVENT RECOVERY)

Activated carbon (AC) for solvent recovery is used in a cyclic process where it is alternately exposed to the target substance and then regenerated by the removal of the target substance. For solvent recovery to be effective, the VOC inlet concentration should be at least 700 ppm. Regeneration of the AC is accomplished by heating, usually by passing low-pressure (e.g., 5 psig) steam over the AC to raise the temperature above the solvent-capture temperature.

There are three main processes for solvent recovery. In a traditional *open-loop recovery system*, a countercurrent air stripper separates VOC from the incoming stream. The resulting VOC air/vapor stream passes through an AC bed. Periodically, the air/vapor stream is switched to an alternate bed, and the first bed is regenerated by passing steam through it. The VOC is recovered from the steam. The VOC-free air stream is freely discharged. Operation of a *closed-loop recovery system* is the same as an open loop system, except that the VOC-free air stream is returned to the air stripper.

For VOC-laden gas flows from 5000 to 100,000 SCFM (2.3 to 47 kL/s), a third type of solvent recovery system involves a *rotor concentrator*. VOCs are continuously adsorbed onto a multilayer, corrugated wheel whose honeycomb structure has been coated with powdered AC. The wheel area is divided into three zones: one for adsorption, one for desorption (i.e., regeneration), and one for cooling. Each of the zones is isolated from the other by tight sealing. The wheel rotates at low speed, continuously exposing new portions of the streams to the appropriate zones. Though the equipment is expensive, operational efficiencies are high—95 to 98%.

[5]The term *activated* refers to the high-temperature removal of tarry substances from the interior of the carbon granule, leaving a highly porous structure.

[6]An *adsorbent* is a substance with high surface area per unit weight, an intricate pore structure, and a hydrophobic surface. An *adsorbent material* traps substances in fluid (liquid and gaseous) form on its exposed surfaces. In addition to activated carbon, other common industrial adsorbents include alumina, bauxite, bone char, Fuller's earth, magnesia, and silica gel.

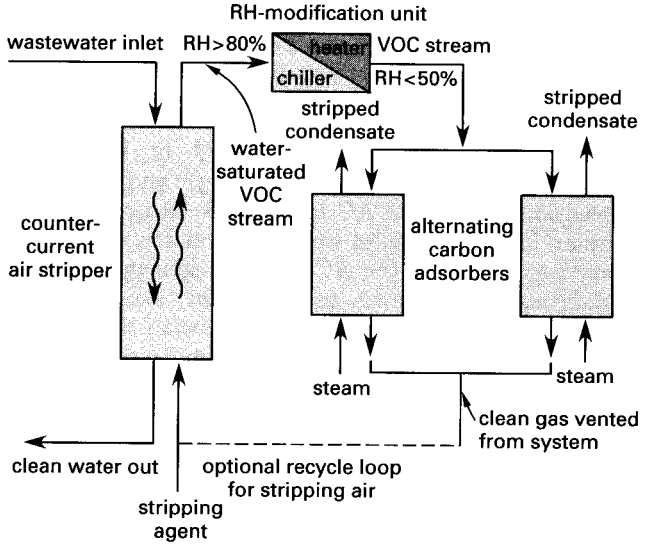

Figure 34.3 *Stripping-AC Process with Recovery*

7. ADSORPTION, HAZARDOUS WASTE

AC is particularly attractive for flue gas cleanup (FGC) at installations that burn spent oil, electrical cable, biosolids (i.e., sewage sludge), waste solvents, or tires as supplemental fuels. As with liquids, flue gases can be cleaned by passing them through fixed AC. Heavy metal dioxins are quickly adsorbed by the AC—in the first 8 in (20 cm) or so. AC injection (direct or spray) can remove 60 to 90% of the target substance present.

The spent AC creates its own waste disposal problem. For some substances (e.g., dioxins), AC can be incinerated. Heavy metals in AC must be removed by a wash process. Another process in use is vitrifying the AC and flyash into a glassy, unleachable substance. *Vitrification* is a high-temperature process that turns incinerator ash into a safe, glass-like material. In some processes, heavy-metal salts are recovered separately. No gases and no hazardous wastes are formed.

8. ADVANCED FLUE GAS CLEANUP

Most air pollution control systems reduce NOx in the burner and remove SOx in the stack. *Advanced flue gas cleanup* (AFGC) methods combine processes to remove both NOx and SOx in the stack. Particulate matter is removed by an electrostatic precipitator or baghouse as is typical. Promising AFGC methods include wet scrubbing with metal chelates such as ferrous ethylenediaminetetraacetate (Fe(II)-EDTA) (NOx/SOx removal efficiencies of 60%/90%), adding sodium hydroxide injection to dry scrubbing operations (35% NOx removal), in-duct sorbent injection of urea (80%/NOx removal), in-duct sorbent injection of sodium bicarbonate (35% NOx removal), and the NOXSO process using a fluidized-bed of sodium-impregnated alumina sorbent at approximately 250°F (120°C) (70 to 90%/90% NOx/SOx removal).

9. ADVANCED OXIDATION

The term *advanced oxidation* refers to the use of ozone, hydrogen peroxide, ultraviolet radiation, and other exotic methods that produce free hydroxyl radicals (OH^-). (See also Sec. 38: Scrubbing, Chemical.)

Table 34.1 *Relative Oxidation Powers of Common Oxidants*

oxidant	oxidation power (relative to Cl)
fluorine	2.25
hydroxyl radical (OH)	2.05
ozone (O_3)	1.52
permanganate radical (MnO_4)	1.23
chlorine dioxide (ClO_2)	1.10
hypochlorous acid	1.10
chlorine	1.00
bromine	0.80
iodine	0.40
oxygen	0.29

10. BAGHOUSES

Baghouses have a reputation for excellent particulate removal, down to 0.005 grains/ft^3 (0.18 grains/m^3) (dry), with particulate emissions of 0.01 grains/ft^3 (0.35 grains/m^3) being routine. Removal efficiencies are in excess of 99% and are often as high as 99.99% (weight basis). Fabric filters have a high efficiency for removing particular matter less than 10 μm in size. Because of this, baghouses are effective at collecting air toxics, which preferentially condense on these particles at the baghouse operating temperature—less than 300°F (150°C).

Baghouse filter fabric has micro-sized holes but may be felted or woven, with the material depending on the nature of the flue gas and particulates. Woven fabrics are better suited for lower filtering velocities in the 1 to 2 ft/min (0.3 to 0.7 m/min) range, while felted fabrics are better at 5 ft/min (1.7 m/min). The fabric is often used in tube configuration, but envelopes (i.e., flat bags) and pleated cartridges are also available.

The particulate matter collects on the outside of the bag, forming a cake-like coating. If lime has been introduced into the stream in a previous step, some of the cake will consist of unreacted lime. As the gases pass through this cake, additional neutralizing takes place.

When the pressure drop across the filter reaches a preset limit (usually 6 to 8 iwg (1.5 to 2 kPa)), the cake is dislodged by mechanical shaking, reverse-air cleaning, or pulse-jetting. The dislodged flyash cake falls into collection hoppers below the bags. Flyash is transported by pressure- or vacuum-conveying systems to the conditioning system (consisting of surge bins, rotary feeders, and pug mills).

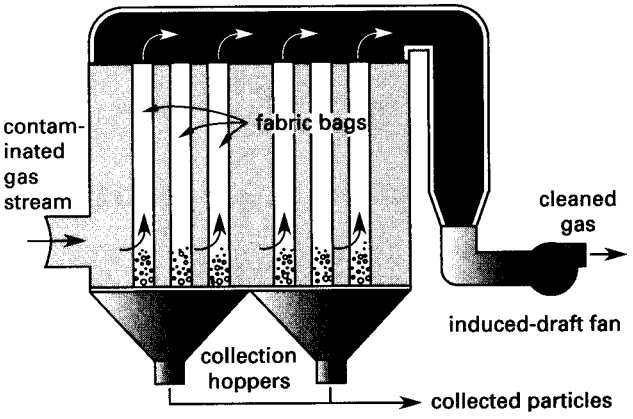

Figure 34.4 *Typical Baghouse*

Baghouses are characterized by their air-to-cloth ratios and pressure drop. The *air-to-cloth ratio*, also known as *filter ratio, superficial face velocity*, and *filtering velocity*, is the ratio of the air volumetric flow rate in ft^3/min (m^3/s) to the exposed surface area in ft^2 (m^2). After canceling, the units are ft/min (m/s), hence the name *filtering velocity*. The higher the ratio, the smaller the baghouse and the higher the pressure drop. Shaker- and reverse-air baghouses with woven fabrics have typical air-to-cloth ratios ranging from 2.0 to 2.5 ft/min (0.01 to 0.0125 m/s). Pulse-jet collectors with felted fabrics have higher ratios, ranging from 3.5 to 5.0 ft/min (0.0175 to 0.025 m/s).

Advantages of baghouses include high efficiency and performance that is essentially independent of flow rate, particle size, and particle (electrical) resistivity. Also, baghouses produce the lowest opacity (generally less than 10, which is virtually invisible). Disadvantages include clogging, difficult cleaning, and bag breakage.

11. BIOREMEDIATION

Bioremediation encompasses the methods of biofiltration, bioreaction, bioreclamation, activated sludge, trickle filtration, fixed-film biological treatment, landfilling, and injection wells (for in situ treatment of soils and groundwater). Bioremediation relies on microorganisms in a moist, oxygen-rich environment to oxidize solid, liquid, or gaseous organic compounds, producing carbon dioxide and water. Bioremediation is effective for removing volatile organic compounds (VOCs) and easy-to-degrade organic compounds such as BTEXs (benzene, toluene, ethylbenzene, and xylene).[7] Wood-preserving wastes, such as creosote and other polynuclear aromatic hydrocarbons (PAHs), can also be treated.

Bioremediation can be carried out in open tanks, packed columns, beds of porous synthetic materials, composting piles, or soil. The effectiveness of bioremediation depends on the nature of the process, the time and physical space available, and the degradability of the substance. Table 34.2 categorizes gases according to their general degradabilities.

Table 34.2 *Degradability of Volatile Organic and Inorganic Gases*

rapidly degradable VOCs	rapidly reactive VICs	slowly degradable VOCs	very slowly degradable VOCs
alcohols	H_2S	hydrocarbons[a]	halogenated hydrocarbons[b]
aldehydes	NOx (but not N_2O)	phenols	polyaromatic hydrocarbons
ketones	SO_2	methylene chloride	CS_2
ethers	HCl		
esters	NH_3		
organic acids	PH_3		
amines	SiH_4		
thiols	HF		
other molecules containing O, N, or S functional groups			

[a] Aliphatics degrade faster than aromatics, such as xylene, toluene, benzene, and styrene.
[b] such as trichloroethylene, trichloroethane, carbon tetrachloride, and pentachlorophenol

Though slow, limited by microorganisms with the specific affinity for the chemicals present, and susceptible to compounds that are toxic to the microorganisms, bioremediation has the advantage of destroying substances rather than merely concentrating them. Bioremediation is less effective when a variety of different compounds are present simultaneously.

12. BIOFILTRATION

The term *biofiltration* refers to the use of composting and soil beds. A *biofilter* is a bed of soil or compost through which runs a distribution system of perforated pipe. Contaminated air or liquid flows through the pipes and into the bed. Volatile organic compounds (VOCs) are oxidized to CO_2 by microorganisms. Volatile inorganic compounds (VICs) are oxidized to acids (e.g., HNO_3 and H_2SO_4) and salts.

Biofilters require no fuel or chemicals when processing VOCs, and the operational lifetime is essentially infinite. For VICs, the lifetime depends on the soil's capacity to neutralize acids. Though reaction times are long and absorption capacities are low (hence the large areas required), the oxidation continually regenerates (rather than depletes) the treatment capacity. Once operational, biofiltration is probably the least expensive method of eliminating VOCs and VICs.

The *removal efficiency* of a biofilter is given by Eq. 34.1. k is an empirical *reaction rate constant*, and t is the *bed residence time* of the carrier fluid (water or air) in the bed. The reaction rate constant depends on the temperature but is primarily a function of the biodegradability

[7] BTEXs are common ingredients in gasoline.

of the target substance. Biofiltration typically removes 80 to 99% of volatile organic and inorganic compounds (VOCs and VICs).

$$\eta = 1 - \frac{C_{\text{out}}}{C_{\text{in}}} = 1 - e^{-kt} \qquad 34.1$$

13. BIOREACTION

Bioreactors (reactor tanks) are open or closed tanks containing dozens or hundreds of slowly rotating disks covered with a biological film of microorganisms (i.e., colonies). Closed tanks can be used to maintain anaerobic or other design atmosphere conditions. For example, methanotrophic bacteria are useful in breaking down chlorinated hydrocarbons (e.g., trichlorethylene (TCE), dichloroethylene (DCE), and vinyl chloride (VC)) that would otherwise be considered nonbiodegradable. Methanotrophic bacteria derive their food from methane gas that is added to the bioreactor. An enzyme, known as MMO, secreted by the bacteria breaks down the chlorinated hydrocarbons.

14. BIOVENTING

Bioventing is the treatment of contaminated soil in a large plastic-covered tank. Clean air, water, and nutrients are continuously supplied to the tank while off-gases are suctioned off. The off-gas is cleaned with activated carbon (AC) adsorption or with thermal or catalytic oxidation prior to discharge. Bioventing has been used successfully to remove volatile hydrocarbon compounds (e.g., gasoline and BTEX compounds) from soil.

15. COAL CONDITIONING

Coal intended for electrical generating plants can be modified into "self-scrubbing" coal by conditioning prior to combustion. Conditioning consists of physical separation by size, by cleaning (e.g., cycloning to remove noncombustible material, including up to 90% of the pyritic sulfur), and by the optional addition of limestone and other additives to capture SO_2 during combustion. Small-sized material is pelletized to reduce loss of fines and particulate emissions (dust).

16. CYCLONE SEPARATORS

Inertial separators of the *double-vortex, single cyclone* variety are suitable for collecting medium- and large-sized (i.e., greater than 15 μm) particles from spot sources. During operation, particulate matter in the incoming gas stream spirals downward at the outside and upward at the inside.[8] The particles, because of their greater mass, move toward the outside wall, where they drop into a collection bin.

[8]The number of gas revolutions varies approximately between 0.5 and 10.0, with averages of 1.5 revolutions for simple cyclones and 5 revolutions for high-efficiency cyclones.

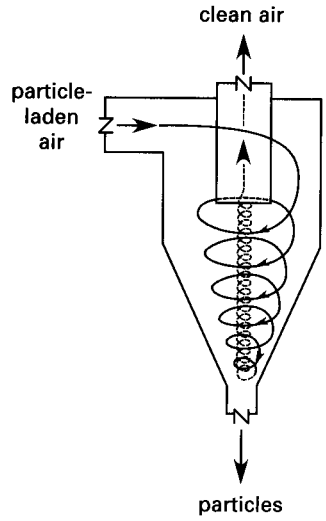

Figure 34.5 *Double-Vortex, Single Cyclone*

The *cut size* is the diameter of particles collected with a 50% efficiency. Separation efficiency varies directly with (a) particle diameter, (b) particle density, (c) inlet velocity, (d) cyclone body length (ratio of cyclone body diameter to outlet diameter), (e) smoothness of inner wall, (f) number of gas revolutions, and (g) amount of particles in the flow. Collection efficiency decreases with increases in (a) gas viscosity, (b) gas density, (c) cyclone diameter, (d) gas outlet diameter, (e) gas inlet duct width, and (f) inlet area.

Collection efficiencies are not particularly high, and dusts (5 to 10 μm) are too fine for most cyclones. For geometrically similar cyclones, the collection efficiency varies directly with the dimensionless *separation factor*, S.

$$S = \frac{\text{v}_{\text{inlet}}^2}{rg} \qquad 34.2$$

Pressure drop, h, in feet of air across a cyclone can be roughly (i.e., with an accuracy of only approximately $\pm 30\%$) estimated by Eq. 34.3. H and B are the height and width of the rectangular cyclone inlet duct, respectively; D is the gas exit duct diameter; and K is an empirical constant that varies from approximately 7.5 to 18.4, with $K = 13$ being a common design value.

$$h = \frac{KBH\text{v}_{\text{inlet}}^2}{2gD^2} \qquad 34.3$$

17. DECHLORINATION

Industrial and municipal wastewaters containing excessive amounts of *total residual chlorine* (TRC) must be dechlorinated prior to discharge. Sulfur dioxide, sodium metabisulfate, and sulfite salts are effective dechlorinating agents. For sulfur dioxide, the dose is approximately 0.9 lbm per pound (kg per kg) of chlorine to be removed. Reaction is essentially instantaneous, being completed within ten pipe diameters at turbulent flow. For open

channels, a submerged weir may be necessary to obtain the necessary turbulence. TRC is reduced to less than detectable levels.

18. ELECTROSTATIC PRECIPITATORS

Electrostatic precipitators (ESPs) are used to remove particulate matter from gas streams. Collection efficiency for particulate matter is usually in the 95 to 99% range. ESPs are preferred over scrubbers because they are more economical to operate, dependable, and predictable, and because they don't produce a moisture plume.

ESPs used on steam generator/electrical utility units treat gas that is approximately 280 to 300°F (140 to 150°C) with moisture being superheated.[9] This high temperature enhances buoyancy and plume dissipation. However, ESPs generally cannot be used with moist flows, mists, or sticky or hygroscopic particles. Scrubbers should be used in those cases. Relatively humid flows can be treated, although entrained water droplets can insulate particles, lowering their resistivities.

In operation, the gas passes over negatively charged tungsten *corona wires* or grids. Particles are attracted to positively charged collection plates.[10] The speed at which the particles move toward the plate is known as the *drift velocity*, w. Drift velocity is approximately 0.20 to 0.30 ft/sec (0.06 to 0.09 m/s), with 0.25 ft/sec (0.075 m/s) being a reasonable design value. Periodically, *rappers* vibrate the collection plates and dislodge the particles, which drop into collection hoppers.

One of the most important factors affecting the collection efficiency is the *specific collection area* (SCA), the area (in ft^2) of the collection plates divided by the volumetric flow rate (in actual ft^3/min) of the air. The higher the SCA, the higher will be the collection efficiency, with 900 ft^2/1000 ft^3/min (3000 m^2/1000 m^3/min) being at the high end of the scale. Pressure drop across ESPs is low (e.g., less than approximately 0.5 iwg (0.13 kPa)).

Use of ESPs is most efficient when particles have resistivities in the 10^{10} to 10^{14} Ω·cm range. If the particle resistivity is much lower, particles may give up their charge upon contacting the collection plate and become reentrained in (i.e., reintroduced into) the gas. If the resistivity is too high, the particles may be difficult to dislodge and may insulate the collection plates. Very small particles (0.1 to 1.0 μm) reduce the corona efficiency, and particles less than 2 to 3 μm are more easily reentrained.

[9]The flue gas, at approximately 1400°F (760°C), is cooled to this temperature range in a conditioning tower. Injected water increases the moisture content of the flue gas to approximately 25% by volume.

[10]The *tubular ESP*, used for collecting moist or sticky particles, is a variation on this design.

The theoretical efficiency of a plate precipitator is calculated from Eq. 34.4.[11] K is a measure of the ease with which the particles can be captured, and C depends on the precipitator size, gas velocity and volume, and voltage. K and C are constants for a particular installation. t is the time the particle remains in the electrical field. w is the drift velocity, A_p is the collection plate area, and Q is the volumetric air flow rate.

$$\eta = 1 - K^{Ct} = 1 - e^{\frac{-wA_p}{Q}} \qquad 34.4$$

Advantages of ESPs include high reliability, low maintenance, low power requirements, and low pressure drop. Disadvantages are sensitivity to particle size and resistivity, and the need to heat ESPs during start-up and shut-down to avoid corrosion from acid gas condensation.

Table 34.3 *Typical Electrostatic Precipitator Design Parameters*

parameter	typical range U.S.	SI
efficiency	90 to 98%	
gas velocity	2 to 4 ft/sec	0.6 to 1.2 m/s
gas temperature		
standard	≤700°F	≤370°C
high-temperature	≤1000°F	≤540°C
special	≤1300°F	≤700°C
drift velocity	0.1 to 0.7 ft/sec	0.03 to 0.21 m/s
treatment/ residence time	2 to 10 sec	
draft pressure loss	0.1 to 0.5 iwg	0.025 to 0.125 kPa
plate spacing	12 to 16 in	30 to 41 cm
plate height	30 to 50 ft	9 to 15 m
plate length/ height ratio	1.0 to 2.0	
applied voltage	30 to 75 kV	

19. FLUE GAS RECIRCULATION

NOx emissions can be reduced when thermal dissociation is the primary NOx source (as it is when low-nitrogen fuels such as natural gas are burned) by recirculating a portion (15 to 25%) of the flue gas back into the furnace. This process is known as *flue gas recirculation* (FGR). The recirculated gas absorbs heat energy from the flame and lowers the peak temperature. Thermal NOx formation can be reduced by up to 50%. The recirculated gas should not be more than 600°F (315°C).

20. FLUIDIZED-BED COMBUSTORS

Fluidized-bed combustors (FBCs) are increasingly being used in steam/electric generation systems and for destruction of hazardous wastes. A *bubbling bed FBC*,

[11]Design of ESPs is almost entirely empirical, being based on previous experience with similar processes or pilot studies.

as shown in Fig. 34.6, consists of four major components: (a) a windbox (plenum) that receives the fluidizing/combustion air, (b) an air distribution plate that transmits the air at 10 to 30 ft/sec (3 to 9 m/s) from the windbox to the bed and prevents the bed material from sifting into the windbox, (c) the fluid bed of inert material (usually sand or product ash), and (d) the freeboard area above the bed.

During the operation of a bubbling bed fluidized-bed combustor, the inert bed is levitated by the upcoming air, taking on many characteristics of a fluid (hence, the name FBC). The bed "boils" vigorously, offering an extremely large heat-transfer area, resulting in the thorough mixing of feed combustibles and air. Combustible material usually represents less than 1% of the bed mass, so the rest of the bed acts as a large thermal flywheel.

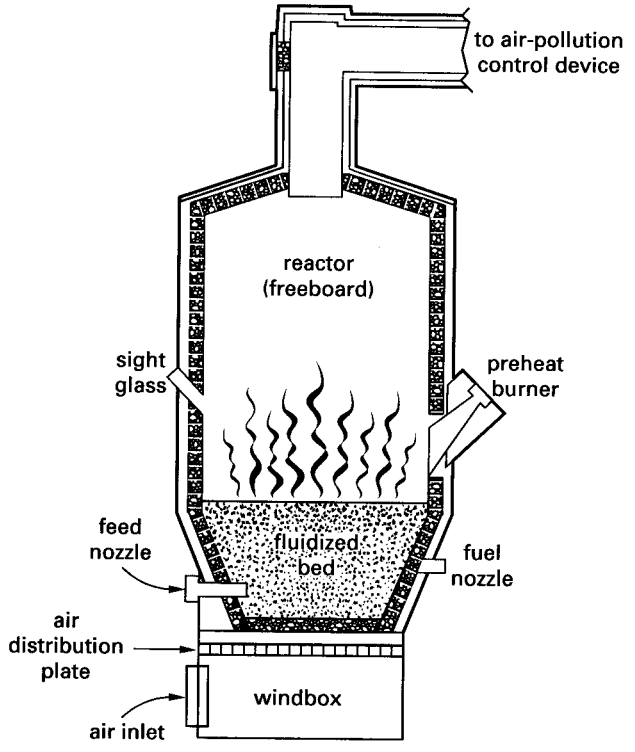

Figure 34.6 *Fluidized-Bed Combustor*

Combustion of volatile materials is completed in the freeboard area. Ash is generally reduced to small size so that it exits with the flue gas. In some cases (e.g., deliberate pelletization or wastes with high ash content), ash can accumulate in the bed. The fluid nature of the bed allows the ash to float on its surface, where it is removed through an overflow drain.

Most FBC systems use forced-air with a single blower at the front end. If there are significant losses due to heat recovery or pollution control systems, an exhaust fan may also be used. In that case, the *null (balanced draft) point* should be in the freeboard area.

Large variations in the composition of the flue gases (known as *puffing*) is minimized by the long residence time and the large heat reservoir of the bed. Air pollution control equipment common to most boilers and incinerators is used with fluidized-bed combustors. Either wet scrubbers or baghouses can be used.

The temperature of the bed can be as high as approximately 1900°F (1040°C), though in most applications, temperatures this high are neither required nor desirable.[12] Most systems operate in the 1400 to 1650°F (760 to 900°C) range.

Three main options exist for reducing temperatures with overautogeneous fuels:[13] (a) Water can be injected into the bed. This has the disadvantage of reducing downstream heat recovery. (b) Excess air can be injected. This requires the entire system to be sized for the excess air, increasing its cost. (c) Heat-exchange coils can be placed within the bed itself, in which case, the name *fluidized-bed boiler* is applicable.

Air can be preheated to approximately 1000 to 1250°F (540 to 680°C) for use with subautogenous fuels, or auxiliary fuel can be used.

Contempory FBC boilers for steam/electricity generation are typically of the *circulating fluidized-bed boiler design*. An important aspect of FBC boiler operation is the in-bed gas desulfurization and dechlorination that occurs when limestone and other solid reagents are injected into the combustion area. In addition, circulating fluidized-bed boilers have very low NOx emissions (i.e., less than 200 ppm).

21. INJECTION WELLS

Properly treated and stabilized liquid and low-viscosity wastes can be injected under high pressure into appropriate strata 2000 to 6000 ft (600 to 1800 m) below the surface. The wastes displace natural fluids, and the injection well is capped to maintain the pressure. Injection wells fail primarily by waste plumes through fractures, cracks, fault slips, and seepage around the well casing.

22. INCINERATORS, FLUIDIZED-BED COMBUSTION

In an FBC, combustion is efficient and excess air required is low (e.g., 25 to 50%). Destruction is essentially complete due to the long residence time (5 to 8 sec for gases, and even longer for solids), high turbulence, and exposure to oxygen. Combustion control is simple, and combustion is often maintained within a

[12] It is a common misconception that extremely high temperatures are required to destroy hazardous waste.

[13] A *subautogenous waste* has a heating value too low to sustain combustion and requires a supplemental fuel. Conversely, an *overautogeneous waste* has a heating value in excess of what is required to sustain combustion and requires temperature control.

15°F (8°C) band. Both overautogeneous and subautogenous feeds can be handled. Due to the thermal mass of the bed, the FBC temperature drops slowly—at the rate of about 10°F/hr (5°C/h) after shutdown. Start-up is fast and operation can be intermittent.

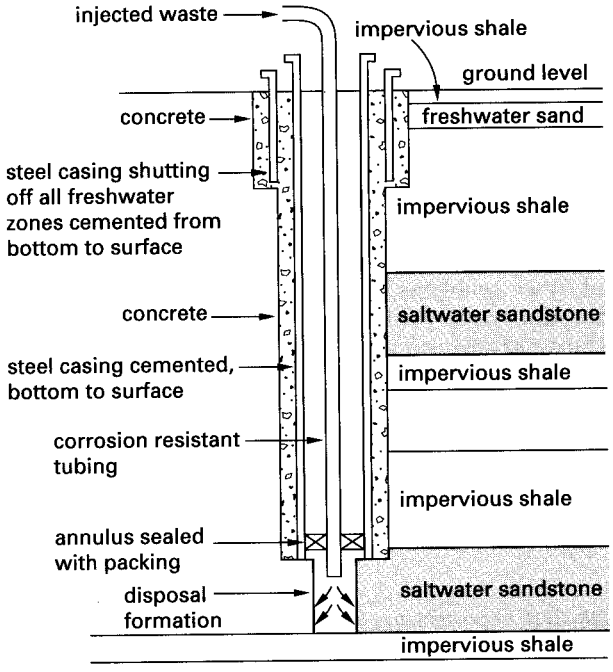

Figure 34.7 *Typical Injection Well Installation*

Relative to other hazardous waste disposal methods, NOx and metal emissions are low, and the organic content of the ash is very low (e.g., below 1%). Because of the long residence time, FBC systems do not usually require afterburners or secondary combustion chambers (SCCs). Due to the turbulent combustion process, the combustion temperature can be 200 to 300°F (110 to 170°C) lower than in rotary kilns. These factors translate into fuel savings, fewer or no NOx emissions, and lower metal emissions.

Most limitations of FBC systems relate to the feed. The feed must be of a form (small size and roughly regular in shape) that can be fluidized. This makes FBCs ideal for non-atomizable liquids, slurries, sludges, tars, and granular solids. It is more appropriate (and economical) to destroy atomizable liquid wastes in a boiler or special injection furnace and large bulky wastes in a rotary kiln or incinerator.

FBCs are usually inapplicable when the feed material or its ash melts below the bed temperature.[14] If the feed melts, it will agglomerate and defluidize the bed. When it is necessary to burn a feed with low melting temperature, two methods can be used. The bed can be operated as a *chemically active bed*, where operation is close to but below the ash melting point of 1350 to 1450°F (730 to 790°C). A small amount of controlled melting is permitted to occur, and the agglomerated ash is removed.

When a higher temperature is desirable in order to destroy hazardous materials, the melting point of feed can be increased by injecting low-cost additives (e.g., calcium hydroxide or kaolin clay). These combine with salts of alkali metals to form refractory-like materials with melting points in the 1950 to 2350°F (1070 to 1290°C) range.

The design of a fluidizing-bed incinerator starts with a heat balance. Energy enters the FBC during combustion of the feed and auxiliary fuel and from sensible heat contributions of the air and fuel. Some of the heat is recovered and reused. The remainder of the heat is lost through sensible heating of the combustion products, water vapor, excess air, and ash, and through radiation from the combustor vessel and associated equipment. Since these items may not all be known in advance, the following assumptions are reasonable.

- Radiation losses are approximately 5%.
- Sensible heat losses from the ash are minimal, particularly if the feed contains significant amounts of moisture.
- Excess air will be approximately 40%.
- Combustion temperature will be approximately 1400°F (760°C).
- If air is preheated, the preheat temperature will be approximately 1000°F (540°C).

The fuel's *specific feed characteristic* (SFC) is the ratio of the higher (gross) heating value to the moisture content. Typical values range from a low of approximately 1000 Btu/lbm (2300 kJ/kg) for wastewater treatment plant biosolids to more than 60,000 Btu/lbm (140 MJ/kg) for barks, sawdust, and RDF.[15] Making the previous assumptions and using the SFC as an indicator, the following generalizations can be made:

- Fuels with SFCs less than 2600 Btu/lbm (6060 kJ/kg) require a 1000°F (540°C) hot windbox, and are autogenous at that value and subautogenous below that value. The SFC drops to 2400 Btu/lbm (5600 kJ/kg) with air preheated to 1200°F (650°C). Below the subautogenous SFC, water evaporation is the controlling design factor, and auxiliary fuel is required.
- Fuels with an SFC of 4000 Btu/lbm (9300 kJ/kg) are autogenous with a cold windbox and are overautogenous above that value. Combustion is the controlling design factor for overautogenous SFCs.

[14]The melting temperature of a eutectic mixture of two components may be lower than the individual melting temperatures.

[15]Although the units are the same, the specific feed characteristic is not the same as the heating value.

Example 34.1

A biosolid sludge is dewatered to 75% water by weight. The solids have a higher heating value of 6500 Btu/lbm. The dewatered sludge enters a fluidized-bed combustor with a 1000°F windbox at the rate of 15,000 lbm/hr. (a) What is the specific feed characteristic? (b) Approximately what energy (in Btu/hr) must the auxiliary fuel supply?

Solution

(a) The dewatered sludge consists of 25% combustible solids and 75% moisture. The total mass of sludge required to contain 1.0 lbm of water is

$$m_{\text{sludge}} = \frac{m_w}{x_w} = \frac{1 \text{ lbm}}{0.75} = 1.333 \text{ lbm}$$

The mass of combustible solids is

$$m_{\text{solids}} = 0.25 m_{\text{sludge}} = (0.25)(1.333 \text{ lbm}) = 0.3333 \text{ lbm}$$

The specific feed characteristic is

$$\text{SFC} = \frac{\text{total heat of combustion}}{m_w} = \frac{m_{\text{solid}}\text{HHV}}{m_w} = \frac{(0.3333 \text{ lbm})\left(6500 \frac{\text{Btu}}{\text{lbm}}\right)}{1 \text{ lbm}} = 2166 \text{ Btu/lbm}$$

(b) Making the assumptions discussed, operation with a 1000°F hot windbox requires a SFC of approximately 2600 Btu/lbm. Therefore, the energy per pound of water in the fuel that an auxiliary fuel must provide is

$$2600 \text{ Btu} - 2166 \text{ Btu} = 434 \text{ Btu}$$

The energy supplied by the auxiliary fuel is

$$\dot{m}_{\text{fuel}} x_w (\text{SFC deficit}) = \left(15{,}000 \frac{\text{lbm}}{\text{hr}}\right)(0.75) \times \left(434 \frac{\text{Btu}}{\text{lbm}}\right) = 4.88 \times 10^6 \text{ Btu/hr}$$

23. INCINERATION, GENERAL

Most rotary kiln and liquid injection incinerators have primary and *secondary combustion chambers* (SCCs). Kiln temperatures are approximately 1200 to 1400°F (650 to 760°C) for soil incineration and up to 1700°F (930°C) for other waste types.[16] SCC temperatures are higher—1800°F (980°C) for most hazardous wastes and 2200°F (1200°C) for liquid PCBs. The waste heat may be recovered in a boiler, but the combustion gas must be cooled prior to further processing. *Thermal ballast* can be accomplished by injecting large amounts of excess air (typical when liquid fuels are burned) or by quenching with a water-spray (typical in rotary kilns).

SCCs are necessary to destroy toxics in the off-gases. SCCs are vertical units with high-swirl vortex-type burners. These produce high *destruction removal efficiencies* (DREs) with low retention times (e.g., 0.5 sec) and moderate-to-high temperatures, even for chlorinated compounds. When soil with fine clay is incinerated, fines can build up in the SCC, causing slagging and other problems. A refractory-lined cyclone located after the primary combustion chamber can be used to reduce particle carryover to the SCC.

Prior to full operation, incinerators must be tested in a trial burn with a *principal organic hazardous constituent* (POHC) that is in or has been added to the waste. The POHC must be destroyed with a DRE of at least 99.99% by weight.

Table 34.4 *Representative Incinerator Performance*

	type of incinerator/use			
			soil incinerators	
	rotary kiln	liquid injection	hazardous	nonhazardous
waste heating value,				
(Btu/lbm)	15,000	20,000	0	0
(MJ/kg)	35	46	0	0
kiln temp				
(°F)	1700	–	1650	850
(°C)	925	–	900	450
SCC temp				
(°F)	1800–2200	2000–2200	1800	1400
(°C)	980–1200	1100–1200	980	750
SCC mean residence time (sec)	2	2	2	1
O_2 in stack gas (%)	10%	12%	9%	6%

For nontoxic organics, a DRE of 95% is a common requirement. Hazardous wastes require a DRE of 99.99%. Certain hazardous wastes, including PCBs and dioxins, require a 99.9999% DRE. This is known as the *six nines rule*.

[16]Temperatures higher than 1400°F (760°C) may cause incinerated soil to vitrify and clog the incinerator.

Emission limitations of some pollutants depend on the incoming concentration and the height of the stack.[17] Thus, in certain circumstances, simply raising the stack is the most effective method of being in compliance. This is considered justified on the basis that ground-level concentrations will be lower with higher stacks.

Rules of thumb regarding incinerator performance are:

- Stoichiometric combustion requires approximately 725 lbm (330 kg) of air for each million Btu of fuel or waste burned.
- 100% excess air is required.
- Stack gas dew point is approximately 180°F (80°C).
- Water-spray-quenched flue gas is approximately 40% moisture by weight.

Example 34.2

What is the mass (in lbm/hr) of water required to spray-quench combustion gases from the incineration of hazardous waste with a heating rate of 50 MMBtu/hr? No additional fuel is added to the incinerator.

Solution

Use the rules of thumb. Assume 100% excess air is required. The total dry air required is

$$m_a = \frac{(2)\left(50 \times 10^6 \ \frac{\text{Btu}}{\text{hr}}\right)(725 \text{ lbm})}{10^6 \ \frac{\text{Btu}}{\text{hr}}}$$

$$= 72{,}500 \text{ lbm/hr} \quad \text{[dry]}$$

Since the quenched combustion gas is 40% water by weight, it is 60% dry air by weight. The total mass of wet combustion gas produced per hour is

$$m_t = \frac{m_a}{x_a} = \frac{m_a}{0.6} = \frac{72{,}500 \ \frac{\text{lbm}}{\text{hr}}}{0.6}$$

$$= 1.21 \times 10^5 \text{ lbm/hr}$$

The required mass of quenching water is

$$m_w = x_w m_t = 0.4 m_t = (0.4)\left(1.21 \times 10^5 \ \frac{\text{lbm}}{\text{hr}}\right)$$

$$= 4.84 \times 10^4 \text{ lbm/hr}$$

24. INCINERATION, HAZARDOUS WASTES

Most hazardous waste incinerators use rotary kilns. Waste in solid and paste form enters a rotating drum where it is burned at 1850 to 2200°F (1000 to 1200°C). (See Table 34.4 for other representative performance characteristics.) Slag is removed at the bottom, and toxic gases exit to a tall, vortex secondary combustion chamber (SCC). Gases remain in the SCC for 2 to 4 sec where they are completely burned at approximately 1850°F (1000°C). Liquid wastes are introduced into and destroyed by the SCC as well. Heat from off-gases may be recovered in a boiler. Typical flue gas cleaning processes include electrostatic precipitation, two-stage scrubbing, and NOx removal.

Common problems with hazardous waste incinerators include (a) inadequate combustion efficiency (easily caused by air leakage in the drum and uneven fuel loading) resulting in incomplete combustion of the primary organic hazardous component (POHC), emission of CO, NOx, and *products of incomplete combustion* (also known as *partially incinerated compounds* or PICS) and metals; (b) meeting low dioxin limits; and (c) minimizing the toxicity of slag and flyash.

These problems are addressed by (a) reducing air leaks in the drum and (b) introducing air to the SCC through multiple sets of ports at specific levels. Gas is burned in the SCC in substoichiometric conditions, with the vortex ensuring adequate mixing to obtain complete combustion. Dioxin formation can be reduced by eliminating the waste-heat recovery process, since the lower temperatures present near waste-heat boilers are ideal for dioxin formation. Once formed, dioxin is removed by traditional end-of-pipe methods.

25. INCINERATION, INFRARED

Infrared incineration (II) is effective for reducing dioxins to undetectable levels. The basic II system consists of a waste feed conveyor, an electrical-heated primary chamber, a gas-fired afterburner, and a typical flue gas cleanup (FGC) system (i.e., scrubber, electrostatic precipitator, and/or baghouse). Electrical heating elements heat organic wastes to their combustion temperatures. Off-gas is burned in a secondary combustion chamber (SCC).

26. INCINERATION, LIQUIDS

Liquid-injection incinerators can be used for atomizable liquids. Such incinerators have burners that fire directly into a refractory-lined chamber. If the liquid waste contains salts or metals, a downfired liquid-injection incinerator is used with a submerged quench to capture the molten material. A typical flue gas cleanup (FGC) system (i.e., scrubber, electrostatic precipitator, and/or baghouse) completes the system.

Incineration of organic liquid wastes usually requires little external fuel, since the wastes are overautogenous and have good heating values. The heating value is approximately 20,000 Btu/lbm (47 MJ/kg) for solvents and approximately 8000 to 18,000 Btu/lbm (19 to 42 MJ/kg) for chlorinated compounds.

[17]Some of the metallic pollutants treated this way include antimony, arsenic, barium, beryllium, cadmium, chromium, lead, mercury, silver, and thallium.

27. INCINERATION, OXYGEN-ENRICHED

Oxygen-enriched incineration is intended primarily for dioxin removal and is operationally similar to that of a rotary kiln. However, the burner includes oxidant jets. The jets aspirate furnace gases to provide more oxygen for combustion. Apparent advantages are low NOx production and increased incinerator feed rates.

28. INCINERATION, PLASMA

A wide variety of solid, liquid, and gaseous wastes can be treated in a *plasma incinerator*. Wastes are heated by an electric arc to higher than 5000°F (2760°C), dissociating them into component atoms. Upon cooling, atoms recombine into hydrogen gas, nitrogen gas, carbon monoxide, hydrochloric acid, and particulate carbon. The ash cools to a nonleachable, vitrified matrix. Off-gases pass through a normal train of cyclone, baghouse, and scrubbing operations. The process has a very high DRE. However, energy requirements are high.

29. INCINERATION, SOIL

Incineration can completely decontaminate soil. Incinerators are often thought of as being fixed facilities, as are cement kilns and special-use (e.g., Superfund) incinerators. However, mobile incinerators can be brought to sites when the soil quantities are large (e.g., 2000 to 100,000 tons (1800 to 90,000 Mg)) and enough setup space is available.[18] (See also Incineration, Solids and Sludges.)

30. INCINERATION, SOLIDS AND SLUDGES

Rotary kilns and fluidized-bed incinerators are commonly used to incinerate solids and sludges. The feed system depends on the waste's physical characteristics. Ram feeders are used for boxed or drummed solids. Bulk solids are fed via chutes or screw feeders. Sludges are fed via lances or by premixing with solids.

The constant rotation of the shell moves wastes through rotary kilns and promotes incineration. External fuel is required in rotary kilns if the heating value of the waste is below 1200 Btu/lbm (2800 kJ/mg) (i.e., is subautogenous). Additional fuel is required in the secondary chamber, as well.

Fluidized-bed incinerators work best when the waste is consistent in size and texture. An important benefit is the ability to introduce limestone and other solid reagents to the bed in order to remove HCl and SO_2.

[18]Modified asphalt batch processing plants can be used to incinerate soils contaminated with low-heating value, nonchlorinated hydrocarbons.

31. INCINERATION, VAPORS

Vapor incinerators, also known as *afterburners* and *flares*, convert combustible materials (gases, vapors, and particulate matter) in the stack gas to carbon dioxide and water. Afterburners can be either direct-flame or catalytic in operation.

32. LOW EXCESS-AIR BURNERS

NOx formation in gas-fired boilers can be reduced by maintaining excess air below 5%.[19] *Low excess-air burners* use a forced-draft and self-recirculating combustion chamber configuration to approximate multistaged combustion.

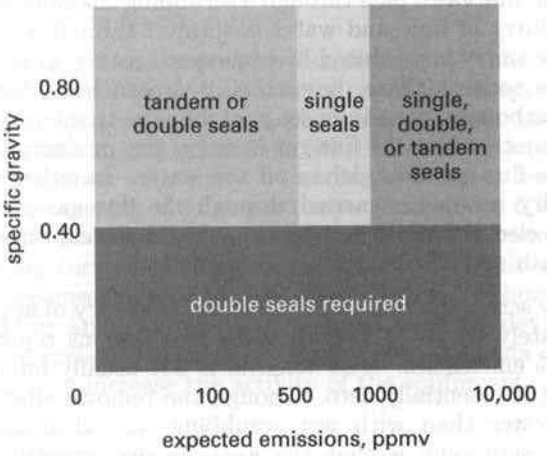
33. LOW-NOx BURNERS

Low (or *ultralow*) *NOx burners* (LNB) in gas-fired applications use a combination of staged-fuel burning and internal flue gas recirculation (FGR). Recirculation within a burner is induced by either the pressure of the fuel gas or other agents (e.g., medium-pressure steam or compressed air).

34. MECHANICAL SEALS

Fugitive emissions from pumps and other rotating equipment can be reduced or eliminated using current technology by the proper selection and installation of mechanical seals. The three major classes of mechanical seals are single seals, tandem seals (dual seals placed next to each other), and double seals (dual seals mounted back-to-back or face-to-face).

The most economical and reliable sealing device is a *single seal*. It has a minimum number of parts and requires no support devices. However, since the pumped product is usually the lubricant for the seal face, small amounts of the product escape into the environment. Emissions are generally below 1000 ppmv, and are often below 100 ppmv.



Tandem seals consist of two seal assemblies separated by a buffer fluid at a pressure lower than the seal-chamber liquid. The primary inner seal operates at full pump pressure. The outer seal operates in the buffer fluid. Tandem seals can achieve zero emissions when used with a vapor recovery system, provided that the pumped product's specific gravity is less than that of the buffer fluid and the product is immiscible with the buffer fluid.

If the buffer fluid used in a tandem dual seal is a controlled substance, emissions from the outer seal must also meet the emission limits. Seals using glycol as the buffer fluid typically achieve zero emissions. Seals using diesel oil or kerosene have emissions in the 25 to 100 ppmv range.

[19]Reducing excess air from 30% to 10%, for example, can reduce NOx emissions by 30%.

Double seals are recommended for hazardous fluids with specific gravities less than 0.4 and are a good choice when a vapor recovery system is not available. (Low specific-gravity liquids do not lubricate the seal well.) Double seals consist of two seal assemblies connected by a common collar; they operate with a barrier fluid kept at a pressure higher than that of the pumped product. Double seals can reduce the emission rate to zero.

Figure 34.8 shows the relationship between typical emissions and specific gravity for the different seal types.

[a]maximum seal size, 6 in (153 mm); maximum pressure, 600 psig (40 bar); maximum speed, 3600 rpm

Figure 34.8 *Representative Emissions to Atmosphere for Mechanical Seals[a] (1 cm from source)*

35. MULTIPLE PIPE CONTAINMENT

The U.S. Environmental Protection Agency (EPA) requires *multiple pipe containment* (MPC) in the storage and transmission of hazardous fluids.[20] MPC systems consist of a carrier pipe or bundle of pipes, a common casing, and a leak detector consisting of redundant instrumentation with automatic shutdown features. Casings are generally not pressurized. If one of the pipes within the bundle develops a leak, the fluid will remain in the casing and the detector will signal an alarm and automatically shut off the liquid flow.

Some of the many factors that go into the design of an MPC system are (a) the number of pipes to be grouped together; (b) the weight and strength of the pipes, carrier, and supports; (c) the compatibility of pipe materials and fluids; (d) differential expansion of the container and carrier pipes; and (e) a method of leak detection.

Carrier pipes within the casing should be supported and separated from each other by internal supports (i.e., perforated baffles within the casing). Carrier pipes pass through oval-shaped holes in the internal supports. Holes are oval and oversized to allow flexing of the carrier pipes due to expansion. Other holes through the internal supports allow venting and draining of the casing in the event of a leak. If multiple detectors are used, isolation baffles can be included to separate the casing into smaller sections.

When a pipe bundle changes elevation as well as direction, the carrier pipes may change their positions relative to one another. A pipe on the outside (i.e., at 3 o'clock) may end up being the lower pipe (i.e., at 6 o'clock).[21] This change in relative positioning is known as *rotation*. Rotation complicates the accommodation of pipes that must enter and exit the bundle at specific locations.

Rotation occurs when a change in direction is located at the top or bottom of an elevation change. Therefore, unless rotation can be tolerated, changes in direction should not be combined with changes in elevation. In Fig. 34.9(a), pipe A remains to the left of pipe B. In Fig. 34.9(b), pipe A starts out to the left of pipe B and ends up above pipe B.

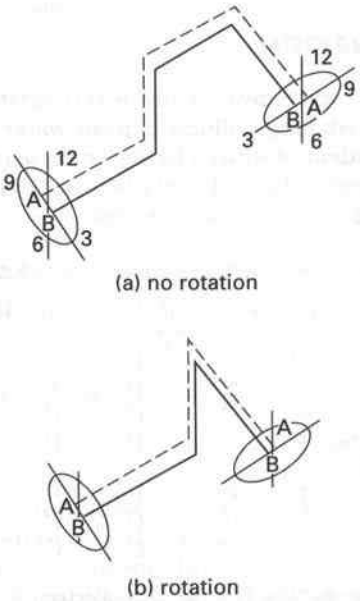


Figure 34.9 *Rotation in Pipe Bundles*

Another problem associated with MPC systems is expansion of the containment casing and carrier pipes caused by differences in ambient and fluid temperatures and the use of different pipe materials. For pipes containing direct changes, there must be space at each elbow to permit the pipe expansion. If both ends of a pipe are fixed, expansion and contraction will cause the pipes to flex unless Z-bends or loops are included.

Differential expansion must be calculated from the largest expected temperature difference using Eq. 34.5.

$$\Delta L = \alpha L \Delta T \qquad 34.5$$

[20]In addition to multiple pipe containment, other factors that contribute to reduction of fugitive emissions are (a) the use of tongue-in-groove flanges, and (b) the reduction of as many nozzles as possible from storage tanks and reactor vessels.

[21]It is important to consistently "face" the same way (e.g., in the direction of flow).

Table 34.5 *Approximate Coefficients of Thermal Expansion of Piping Materials (at 70°F (21°C))*

pipe material	U.S. (ft/ft-°F)	SI (m/m·°C)
carbon steel	6.1×10^{-6}	1.1×10^{-5}
chlorinated polyvinyl chloride (CPVC)	3.8×10^{-5}	6.8×10^{-5}
copper	9.5×10^{-6}	1.7×10^{-5}
fiberglass-reinforced polyethylene (FRP)	8.5×10^{-6}	1.5×10^{-5}
polyethylene (PE)	8.3×10^{-5}	1.5×10^{-4}
polyvinyl chloride (PVC)	3.0×10^{-5}	5.4×10^{-5}
stainless steel	9.1×10^{-6}	1.6×10^{-5}

(Multiply ft/ft-°F by 1.8 to get m/m·°C.)

Computer programs are commonly used to design pipe networks. These programs are helpful in locating guides and anchors and in performing a stress analysis on the final design. Drains, purge points, baffles, and joints are generally chosen by experience.

36. OZONATION

Ozonation is one of several advanced oxidation methods capable of reducing pollutants from water. Ozone is a powerful oxidant produced by electric discharge through liquid oxygen. Ozone is routinely used in the water treatment industry for disinfection.

Table 34.6 *Oxidation of Industrial Wastewater Pollutants*[a]

	Cl_2	ClO_2	$KMnO_4$	O_3	H_2O_2	OH^-
amines	C	P	P	P	P	C
ammonia	C	N	P	N	N	N
bacteria	C	C	C	C	P	C
carbohydrates	P	P	P	P	N	C
chlorinated solvents	P	P	P	P	N	C
phenols	P	C	C	C	P	C
sulfides	C	C	C	C	C	C

[a]C = complete reaction; P = partially effective; N = not effective

37. SCRUBBING, GENERAL

Scrubbing is the act of removing particulate matter from a gaseous stream, although substances in gaseous and liquid forms may also be removed.[22]

38. SCRUBBING, CHEMICAL

Chemical scrubbing using oxidizing compounds such as chlorine, ozone, hypochlorite, or permanganate rapidly destroys volatile organic compounds (VOCs). Efficiencies are typically 95% for highly reactive substances, but are lower for hydrocarbons and substances with low reactivities.

39. SCRUBBING, DRY

Dry scrubbing, also known as *dry absorption* and *semi-dry scrubbing*, is one form of sorbent injection. It is commonly used to remove SO_2 from flue gas. In operation, flue gases pass through a scrubbing chamber where a slurry of lime and water is sprayed through them.[23] The slurry is produced by high-speed rotary atomizers. The sorbent (lime, limestone, hydrated lime, sodium bicarbonate, or sodium sesquicarbonate–trona–reagent) is injected into the flue gas in either dry or slurry form. The flue gas heat drives off the water. In either case, a dry powder is carried through the flue gas system. An electrostatic precipitator or baghouse captures the flyash and calcium sulfate particulates.

Dry scrubbing has an SO_2 removal efficiency of approximately 50 to 75%, with some installations reporting 90% efficiencies. NOx removal is not usually intended and is essentially zero. Though the removal efficiency is lower than with wet scrubbing, an advantage of dry scrubbing is that the waste is dry, requiring no sludge-handling equipment. The lower efficiency may be sufficient in older power plants with less stringent regulations. (See also Sorbent Injection.)

Particulate removal efficiencies of 90% can be achieved. Since wet scrubbers normally have a lower particulate removal efficiency than baghouses, they are usually combined with electrostatic precipitators.

40. SCRUBBING, WET

See Absorption, Gas (Spray Towers).

41. SELECTIVE CATALYTIC REDUCTION

Selective catalytic reduction (SCR) uses ammonia in combination with a catalyst to reduce nitrogen oxides (NOx) to nitrogen gas and water.[24] Vaporized ammonia is injected into the flue gas; the mixture passes through a catalytic reaction bed approximately 0.5 to 1.0 sec later. The reaction bed can be constructed from honeycomb plates or parallel-ridged plates. Alternatively, the reaction bed may consist of a packed bed of rings, pellets, or other shapes. The catalyst lowers the NOx decomposition activation energy. NOx and NH_3 combine on the catalyst's surface, producing nitrogen and water.

[22]As it relates to air pollution control, the term *scrubbing* is loosely used. The term may be used in reference to any process that removes any substance from flue gas. In particular, any process that removes SO_2 by passing flue gas through lime or limestone is referred to as *scrubbing*.

[23]In addition to lime, limestone, sodium carbonate, and magnesium oxide can be used. Because they cost less, lime and limestone are the most common.

[24]Vanadium oxide, titanium, and platinum are metallic catalysts; zeolites and ceramic catalysts are also used.

One mole of ammonia is required for every mole of NOx removed. However, in order to maximize the reduction efficiency, approximately 5 to 10 ppm of unreacted ammonia is left behind.[25] The chemical reaction is

$$O_2 + 4NO + 4NH_3 \longrightarrow 4N_2 + 6H_2O$$

The optimal temperature for SCR is 600 to 700°F (315 to 370°C). Gas velocities are typically around 20 ft/sec (6 m/s). The pressure drop is 3 to 4 iwg (0.75 to 1 kPa). NOx removal efficiency is typically 90% but can range from 70 to 95% depending on the application.[26] SCR produces no liquid waste.

Several conditions can cause deactivation of the catalyst. *Poisoning* occurs when trace quantities of specific materials (e.g., arsenic, lead, phosphorous, other heavy metals, silicon, and sulfur from SO_2) react with the catalyst and lower its activity. Poisoning by SO_2 can be reduced by keeping the flue gas temperature above 608°F (320°C) and/or using poison-resisting compounds. *Masking* (or *plugging*) occurs when the catalytic surface becomes covered with fine particle dust, unburned solids, or ammonium salts. Internal cleaning devices remove surface contaminants such as ash deposits and are used to increase the activity of the equipment.

42. SELECTIVE NONCATALYTIC REDUCTION

Selective noncatalytic reduction (SNCR) involves injecting ammonia or urea into the upper parts of the combustion chamber (or into a thermally favorable location downstream of the combustion chamber) to reduce NOx.[27] SNCR is effective when the oxygen content is low (e.g., 1%) and the combustion temperature is controlled. If the temperature is too high, the NH_3 will react more with oxygen than with NOx, forming even more NOx. If the temperature is too low, the reactions slow and unreacted ammonia enters the flue gas. The optimal temperature range is 1600 to 1750°F (870 to 950°C) for NH_3 injection and up to 1900°F (1040°C) for urea. (In general, the temperature ranges for NH_3 and urea are similar. However, various hydrocarbon additives can be used with urea to lower the temperature range.)

[25]Leftover ammonia in the flue gas is referred to as *ammonia slip* and is usually measured in ppm. 50 to 100 ppm would be considered an excessive ammonia slip. Since NOx and NH_3 react on a 1:1 molar basis, slip is easily calculated. In the following equations, the units can be either molar or volumetric (ppmvd, lbm/hr, mol/hr, scfm, etc.), but they must be consistent.

$$\begin{aligned} NH_{3,slip} &= NH_{3,feed} - NH_{3,reacted} \\ &= NH_{3,feed} - (NOx_{in} - NOx_{out}) \\ &= NH_{3,feed} - (NOx_{in})(\text{removal efficiency}) \end{aligned}$$

[26]Removal efficiencies of 95 to 99% are possible when SCR is used for VOC removal.

[27]*Urea*, which decomposes to NH_3 and carbon dioxide inside the combustion chamber, is safer and easier to handle.

The reactions are

$$6NO + 4NH_3 \longrightarrow 5N_2 + 6H_2O$$
$$6NO_2 + 8NH_3 \longrightarrow N_2 + 12H_2O$$

The NOx reduction efficiency is approximately 20 to 50% with an ammonia slip of 20 to 30 ppm. The actual efficiency is highly dependent on the injection geometries and interrelations between ammonia slip, ash, and sulfur.

Since the NOx reduction efficiency is relatively low, the SNCR process cannot usually satisfy NOx regulations by itself. The use of urea must be balanced against the potential for ammonia slip and the conversion of NO to nitrous oxide. These and other problems relating to formation of ammonium salts have kept SNCR from gaining widespread popularity in small installations.

43. SOIL WASHING

Soil washing is effective in removing heavy metals, wood preserving wastes (PAHs), and BTEX compounds from contaminated soil. Soil washing is a two-step process. In the first step, soil is mixed with water to dissolve the contaminants. Additives are used as required to improve solubility. In the second step, additional water is used to flush the soil and to separate the fine soil from coarser particles. (Semivolatile materials concentrate in the fines.) Metals are extracted by adding chelating agents to the wash water.[28] The contaminated wash water is subsequently treated.

44. SORBENT INJECTION

Sorbent injection (FSI) involves injecting a limestone slurry directly into the upper parts of the combustion chamber (or into a thermally favorable location downstream) to reduce SOx. Heat calcines the limestone into reactive lime. Fast drying prevents wet particles from building up in the duct. Lime particles are captured in a scrubber with or without an electrostatic precipitator (ESP). With only an ESP, the SOx removal efficiency is approximately 50%.

45. SPARGING

Sparging is the process of using air injection wells to bubble air through groundwater. The air pushes volatile contaminants into the overlying soil above the aquifer where they can be captured by vacuum extraction.

[28]A *chelate* is a ring-like molecular structure formed by unshared electrons of neighboring atoms. A *chelating agent (chelant)* is an organic compound in which atoms form bonds with metals in solution. By combining with metal ions, chelates control the damaging effects of trace metal contamination. Ethylenediaminetetraacetic acid (EDTA) types are the leading industrial chelants.

46. STAGED COMBUSTION

Staged combustion methods are primarily used with gas-fired burners to reduce formation of nitrogen oxides (NOx). Both staged-air burner and staged-fuel burner systems are used. *Staged-air burner systems* reduce NOx production 20 to 35% by admitting the combustion air through primary and secondary paths around each fuel nozzle. The fuel burns partially in the fuel-rich zone. Fuel-borne nitrogen is converted to compounds that are subsequently oxidized to nitrogen gas. Secondary air completes combustion and controls the flame size and shape. Combustion temperature is lowered by recirculation of combustion products within the burner. Staged burners have few disadvantages, the main one being longer flames.

In *staged-fuel burner systems*, a portion of the fuel gas is initially burned in a fuel-lean (air-rich) combustion. The peak flame temperature is reduced, with a corresponding reduction in thermal NOx production. The remainder of the fuel is injected through secondary nozzles. Combustion gases from the first stage dilute the combustion in the second stage, reducing peak temperature and oxygen content. Reductions in NOx formation of 50 to 60% are possible. Flame length is less than with staged-air burners, and the required excess air is lower.

47. STRIPPING, AIR

Air strippers are primarily used to remove volatile organic compounds (VOCs) or other target substances from water. In operation, contaminated water enters a stripping tower at the top, and fresh air enters at the bottom. The effectiveness of the process depends on the volatility of the compound, its temperature and concentration, and the liquid-air contact area. However, removal efficiencies of 80 to 90% (and above) are common for VOCs.

There are three types of stripping towers—*packed towers* filled with synthetic *packing media* (polypropylene balls, rings, saddles, etc.), *spray towers*, and (less frequently for VOC removal) *tray towers* with horizontal trays arranged in vertical layers. *Redistribution rings (wall wipers)* prevent channeling down the inside of the tower. (*Channeling* is the flow of liquid through a few narrow paths rather than an over-the-bed packing.) The stripping air is generated by a small blower at the column base. A mist eliminator at the top eliminates entrained water from the air.

As the contaminated water passes over packing media in a packed tower, the target substance leaves the liquid and enters the air where the concentration is lower. The mole fraction of the target substance in the water, x, decreases; the mole fraction of the target substance in the air, y, increases.

The discharged air, known as *off-gas*, is discharged to a process that destroys or recovers the target substance. (Since the quantities are small, recovery is rarer.)

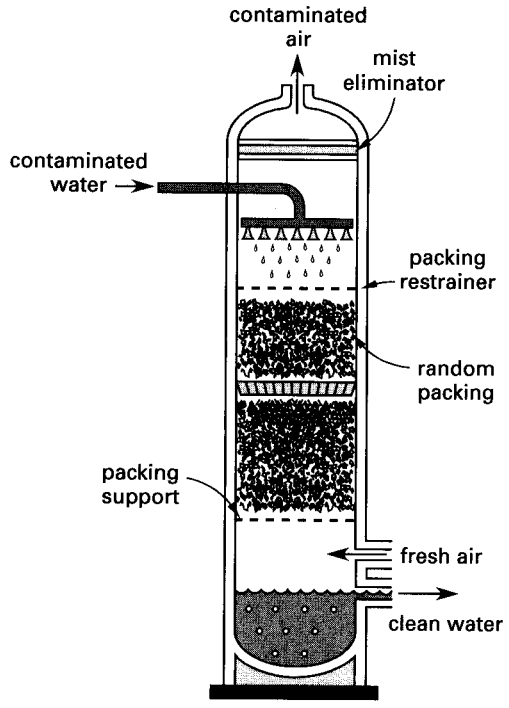

Figure 34.10 *Schematic of Air Stripping Operation*

Destruction of the target substance can be accomplished by flaring, carbon absorption, and incineration. Since flaring is dangerous and carbon absorption creates a secondary waste if the AC is not regenerated, incineration is often preferred.

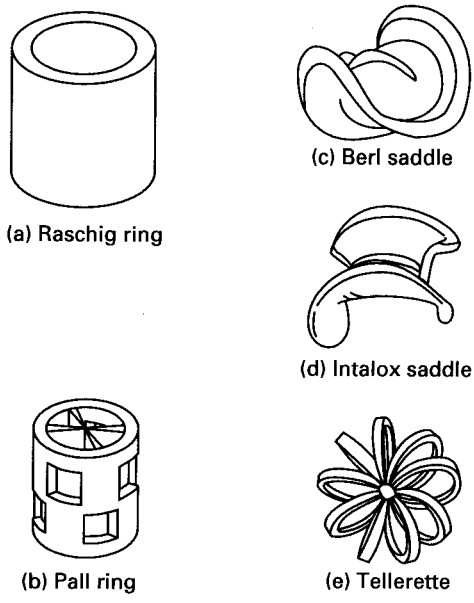

Figure 34.11 *Packing Media Types*

Henry's law, as it applies to water treatment, states that at equilibrium, the vapor pressure of target substance A is directly proportional to the target substance's mole fraction, x_A. (The maximum mole fraction is the

substance's *solubility*.) Table 34.7 lists representative values of Henry's law constant, H.[29] When multiple compounds are present in the water, the *key component* is the one that is the most difficult to remove (i.e., the component with the highest concentration and lowest Henry's constant).

$$p_A = H_A x_A \qquad 34.6$$

The liquid *mass-transfer coefficient*, $K_L a$, is the product of the *coefficient of liquid mass transfer*, K, and the *interfacial area* per volume of packing, a. The mass transfer coefficient is a measure of the efficiency of the air stripper as a whole. The higher the mass transfer coefficient, the higher the efficiency. The $K_L a$ value is largely a function of the size and shape of the packing material, and it is usually obtained from the packing manufacturer or theoretical correlations.

Table 34.7 *Typical Henry's Law Constants for Selected Volatile Organic Compounds (at low pressures and 25°C)*

VOC	Henry's law constant, H (atm)[a]
1,1,2,2-tetrachloroethane	24.02
1,1,2-trichloroethane	47.0
propylene dichloride	156.8
methylene chloride	177.4
chloroform	188.5
1,1,1-trichloroethane	273.56
1,2-dichloroethene	295.8
1,1-dichloroethane	303.0
hexachloroethane	547.7
hexachlorobutadiene	572.7
trichloroethylene	651.0
1,1-dichloroethene	834.03
perchloroethane	1596.0
carbon tetrachloride	1679.17

(Multiply atm by 101.3 to obtain kPa.)
[a]Henry's law indicates that the units of H are atmospheres per mole fraction. Mole fraction is dimensionless and does not appear in the units for H.

For some types of packing, the gas-phase resistance is greater than the liquid-phase resistance, and the gas mass-transfer coefficient, $K_G a$, may be given.

The *stripping factor*, R (the reciprocal of the *absorption factor*), is given by Eq. 34.7. Units for the gas and liquid flow rates, G and L, depend on the correlations used to solve the stripping equations. The air flow rate is limited by the acceptable pressure drop through the tower.

$$R = \frac{HG}{L} \qquad 34.7$$

[29]Henry's law is fairly accurate for most gases when the partial pressure is less than 1 atm. If the partial pressure is greater than 1 atm, Henry's law constants will vary with partial pressure.

The *transfer unit method* is a convenient way of designing and analyzing the performance of stripping towers. A *transfer unit* is a measure of the difficulty of the mass-transfer operation and depends on the solubility and concentrations. The overall number of transfer units is expressed as NTU_{OG} or NTU_{OL} (alternatively, N_{OG} or N_{OL}), depending on whether the gas or liquid resistance dominates.[30] The NTU value depends on the incoming and desired concentrations and the material flow rates.[31]

The *height of the packing*, z, is the effective height of the tower. It is calculated from the NTUs and the *height of a transfer unit*, HTU, using Eq. 34.8. The HTU value depends on the packing media.

$$z = (HTU_{OG})(NTU_{OG}) = (HTU_{OL})(NTU_{OL}) \qquad 34.8$$

Ten percent additional height should be added to the theoretical value as a safety factor. Packing heights greater than 30 to 40 ft (9.1 to 12.2 m) are not recommended since the packing might be crushed, and greater heights produce little or no increase in removal efficiency.

The blower power depends on the packing shape and size and the air-to-water ratio. Typical pressure drops are 0.5 to 1.0 iwg per vertical foot (0.38 to 0.75 kPa/m) of packing. To minimize the blower power requirement, the ratio of tower diameter to gross packing dimension should be between 8 and 15. Blower fan power increases with increasing air-to-water ratios.

A significant problem for air strippers removing contaminants from water is fouling of the packing media through biological growth and solids (e.g., iron complexes) deposition. Biological growth can be inhibited by continuous or batch use of a *biocide* that does not interfere with the off-gas system.[32] Another problem is *flooding*, which occurs when excess liquid flow rates impede the flow of the air.

48. STRIPPING, STEAM

Steam stripping is more effective than air stripping for removing semi- and non-volatile compounds, such as

[30]The gas film resistance controls when the solubility of the target substance in the liquid is high. Conversely, when the solubility is low, the liquid film resistance controls. In flue gas cleanup (FGC) work, the gas film resistance usually controls.
[31]Stripping is one of many mass-transfer operations studied by chemical engineers. Determining the number of transfer units required and the height of a single transfer unit are typical chemical engineering calculations.
[32]A *biocide* is a chemical that kills living things, particularly microorganisms. Biocide categories include chlorinated isocyanurates (used in swimming pool disinfectants and dishwashing detergents), sodium bromide, inorganics (used in wood treatments), quaternaries ("quats") used in hard surface cleaners and sanitizers, and iodophors (used in human skin disinfectants). By comparison, *biostats* do not kill microorganisms already present, but they retard further growth of microorganisms from the moment they are incorporated. Biostats are organic acids and salts (e.g., sodium and potassium benzoate, sorbic acid, and potassium sorbate used "to preserve freshness" in foods).

diesel fuel, oil, and other organic compounds with boiling points up to approximately 400°F (200°C). Operation of a steam stripper is similar to that of an air stripper, except that steam is used in place of the air. Steam strippers can be operated at or below atmospheric pressure. Higher vacuums will remove greater amounts of the compound.

49. THERMAL DESORPTION

Thermal desorption is primarily used to remove volatile organic compounds (VOCs) from contaminated soil. The soil is heated directly or indirectly to approximately 1000°F (540°C) to evaporate the volatiles. This method differs from incineration in that the released gases are not burned but are captured in a subsequent process step (e.g., activated carbon filtration).

50. VACUUM EXTRACTION

Vacuum extraction is used to remove many types of volatile organic compounds (VOCs) from soil. The VOCs are pulled from the soil through a well dug in the contaminated area. Air is withdrawn from the well, vacuuming volatile substances with it.

51. VAPOR CONDENSING

Some vapors can be removed simply by cooling them to below their dew points. Traditional contact- (open) and surface- (closed) condensers can be used.

52. VITRIFICATION

Vitrification melts and forms slag and ash wastes into glass-like pellets. Heavy metals and toxic compounds cannot leach out, and the pellets can be disposed of in hazardous waste landfills. Vitrification can occur in the incineration furnace or in a stand-alone process. Stand-alone vitrification occurs in an electrically heated vessel where the temperature is maintained at 2200 to 2370°F (1200 to 1300°C) for up to 20 hr or so. Since the electric heating is nonturbulent, flue gas cleaning systems are not needed.

53. INDUSTRIAL WASTEWATER TREATMENT PROCESSES

Many industrial processes use water for cooling, rinsing, or mixing. Such water must be treated prior to being discharged to *publicly owned treatment works* (POTWs).[33] Table 34.8 lists some of the polluting characteristics of industrial wastewaters.

[33]Rainwater runoff from some industrial plants can also be a hazardous waste.

Table 34.8 *Types of Pollution from Industrial Wastewater*

whole-effluent toxicity (LC_{50})

Most large-volume industrial wastewaters go through the following processes: (a) flow equalization, (b) neutralization, (c) oil and grease removal, (d) suspended solids removal, (e) metals removal, and (f) VOC removal. These processes are similar, in many cases, to processes with the same names used to treat municipal wastewater in a POTW.

Flow equalization reduces the chance of under- and overloading a treatment process. Equalization of both hydraulic and chemical loading is required. *Hydraulic loading* is usually equalized by storing wastewater during high flow periods and discharging it during periods of low flow. *Chemical loading* is equalized by use of an equalization basin with mechanical mixing or air agitation. Mixing with air has the added advantages of oxidizing reducing compounds, stripping away volatiles, and eliminating odors.

There are two reasons for water *neutralization*. First, the pH of water is regulated and must be between 6.0 and 9.0 when discharged. Second, water that is too acidic or alkaline may not be properly processed by subsequent, particularly biological, processes. The optimum pH for biological processes is between 6.5 and 7.5. The effectiveness of the processes is greatly reduced with pHs below 4.0 and above 9.5.

Acidic water is neutralized by adding lime (oxides and hydroxides of calcium and magnesium), limestone, or some other caustic solution. Alkaline waters are treated with sulfuric or hydrochloric acid or carbon dioxide gas.[34]

Large volumes of oil and grease float to the surface and are skimmed off. Smaller volumes may require a dissolved-air process. Removing emulsified oil is more complex and may require use of chemical coagulants.

[34]In water, carbon dioxide gas forms *carbonic acid.*

The method used to remove suspended solids depends on the solid size. Most industrial plants do not require strainers, bar screens, or fine screens to remove large solids (i.e., those larger than 1 in (25 mm)). *Grit* (i.e., sand and gravel) is removed in grit chambers by simple sedimentation. Fine solids are categorized into *settleable solids* (diameters more than 1 μm) and *colloids* (diameters between 0.001 μm and 1 μm). Settleable solids and colloids are removed in a sedimentation tank, with chemical coagulants or dissolved-air flotation being used to assist colloidal particles in settling out.

Most metal (e.g., lead) removal occurs by precipitating its hydroxide, although precipitation as carbonates or sulfides is also used.[35] A caustic substance (e.g., lime) is added to the water to raise the pH below the solubility limit of the metal ion. When they come out of solution, the metallic compounds are *flocculated* into larger flakes that ultimately settle out. Floc is mechanically removed as inorganic heavy-metal sludge, which has a 96 to 99% water content by weight. The sludge is dewatered in a drying bed, vacuum filter, or filter press to 65 to 85% water. Depending on its composition, the sludge can be landfilled or treated as a hazardous waste by incineration or other methods.

Volatile organic compounds (VOCs) such as benzene and toluene are removed by air stripping or adsorption in activated charcoal (AC) towers. Nonvolatile organic compounds (NVOCs) are removed by biological processes such as lagooning, trickle filtration, and activated sludge.

Although destruction of biological health hazards is not always needed for industrial wastewater, chemical oxidants (see Table 34.1) are still needed to destroy odors, control bacterial growth downstream, and eliminate sulfur compounds.[36] Chemical oxidants can also reduce heavy metals (e.g., iron, manganese, silver, and lead) that were not removed in previous operations.

[35]Ion exchange, activated charcoal, and reverse osmosis methods can be used but may be more expensive.

[36]Meat-packing and dairy (e.g., cheese) plants are examples of industrial processes that require chlorination to destroy bacteria in wastewater.

z	zero air voids

1. SOIL PARTICLE SIZE DISTRIBUTION

Soil is an aggregate of loose mineral and organic particles. *Rock*, on the other hand, exhibits strong and permanent cohesive forces between the mineral particles. From an engineering perspective, the distinction between soil and rock relates to the workability of materials. For example, one practical definition is that soil can be excavated with a backhoe while rock needs to be blasted. The distinction between soil and rock can also be made based on strength, density, and other quantifiable parameters. A geologist or soil scientist might be more interested in how a material has been formed than its workability, and thus might distinguish between soil and rock differently.

The primary mineral components of any soil are gravel, sand, silt, and clay. Organic material can also be present in surface samples. Gravel and sand are classified as coarse-grained soils, while inorganic silt and clay are classified as fine-grained soils. Particle size limits for defining gravel, sand, silt, and clay used in different classification schemes are given in Table 35.1.

The particle size distribution for a coarse soil is found from a sieve test. In a *sieve test*, the soil is passed through a set of sieves of consecutively smaller openings. The particle size distribution for the finer particles of a soil is determined from a *hydrometer test*. This test is based on Stokes' Law, which relates the speed of a particle falling out of suspension to its diameter and solid density. The results of both the sieve and hydrometer tests are graphed as a *particle size distribution*.

USDA	1938	2–100	0.05–2	0.002–0.05	< 0.002
Unified (or USCS)	1953	4.75–75	0.075–4.75	< 0.075	
ASTM	1967	4.75–75	0.075–4.75	< 0.075	
AASHTO	1970	2–75	0.075–2	0.002–0.075	0.001–0.002

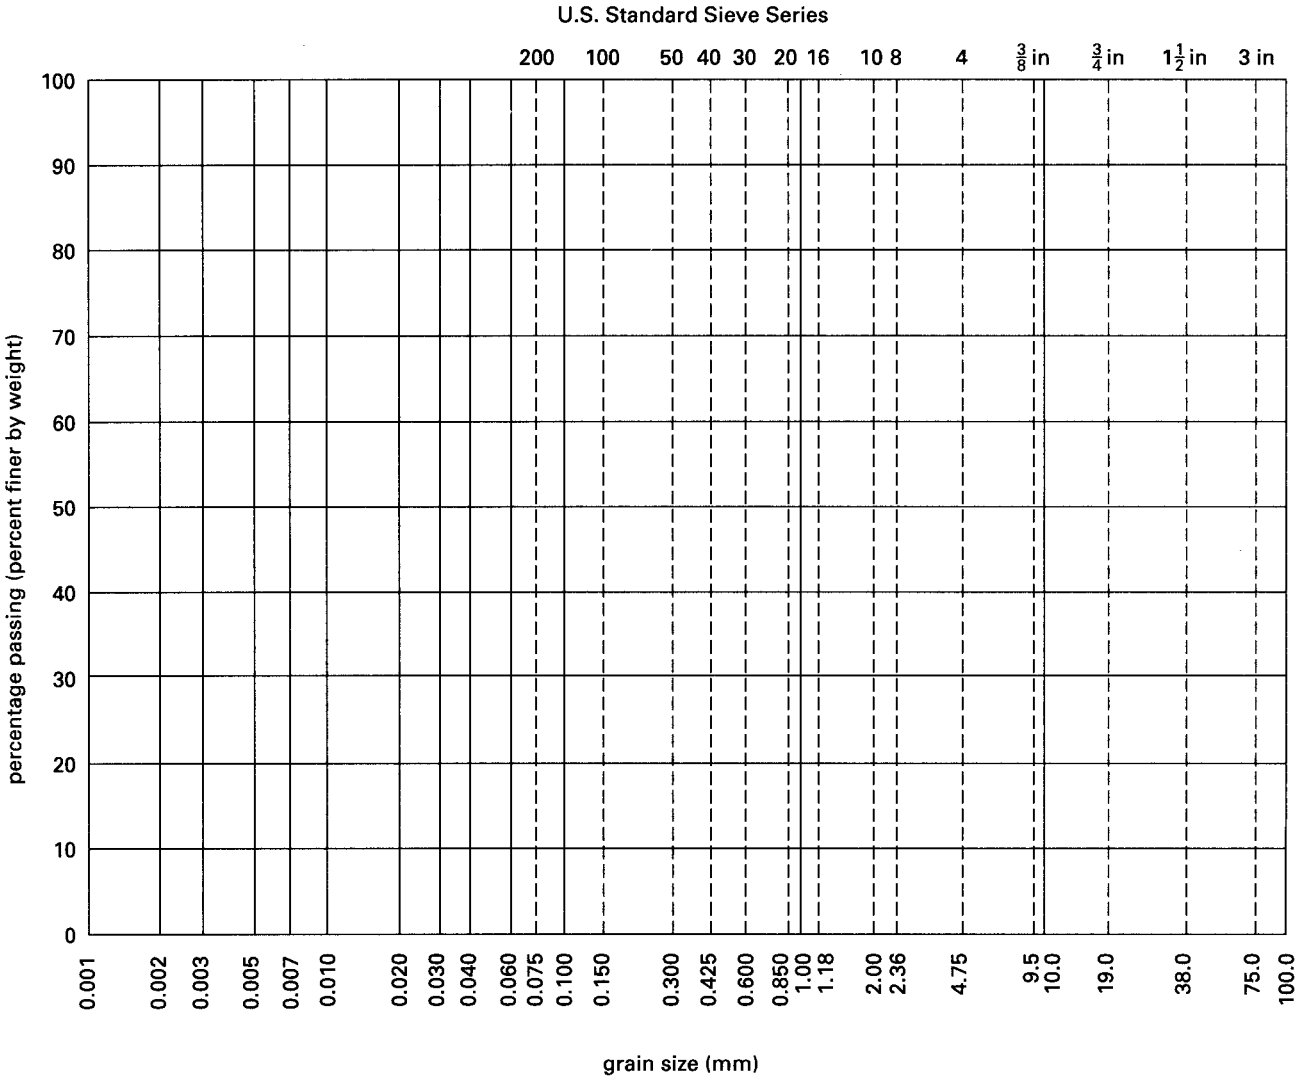

Figure 35.2 *Particle Size Distribution Chart (blank)*

The *Hazen uniformity coefficient*, C_u given by Eq. 35.1, indicates the general shape of the particle size distribution. The diameter, for which only 10% of the particles are finer, is designated as D_{10} and is known as the *effective grain size*.

$$C_u = \frac{D_{60}}{D_{10}} \qquad 35.1$$

If the uniformity coefficient is less than 4 or 5, the soil is considered uniform in particle size, which means that all particle sizes fall within a narrow range. *Well-graded soils* have uniformity coefficients greater than 10 and have a continuous, wide range of particle sizes. *Gap-graded soils* are missing one or more ranges of particle sizes.

Another index of distribution shape is the *coefficient of curvature* (also known as the *coefficient of gradation*), given by Eq. 35.2. The diameters for which 30% and 60% of the particles are finer are designated as D_{30} and D_{60}, respectively. Typical shape parameters are listed in Table 35.3.

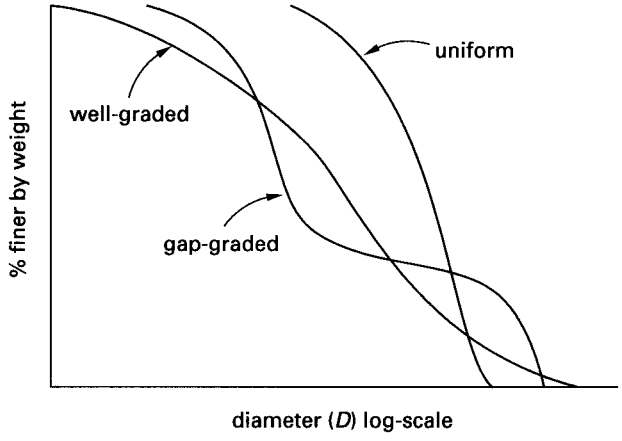

Figure 35.3 *Uniformity in Particle Size Distributions*

$$C_z = \frac{(D_{30})^2}{D_{10}D_{60}} \qquad 35.2$$

Table 35.3 *Typical Uniformity Coefficients*

soil	C_u	C_z
gravel	> 4	1–3
fine sand	5–10	1–3
coarse sand	4–6	
mixture of silty sand and gravel	15–300	
mixture of clay, sand, silt, and gravel	25–1000	

Equations 35.1 and 35.2, as well as various soil classification schemes, require knowing percentages of soil passing through specific sieve sizes. When sieve data are incomplete, the needed values can be interpolated by plotting known data on a *particle size distribution chart*.

2. SOIL CLASSIFICATION

Formal soil classification schemes have been established by a number of organizations. These schemes standardize the way that soils are described and group similar soils by the characteristics that are important in determining behavior. The classification of a soil depends mostly on the percentages of gravel, sand, silt, and clay. Usually it will also depend on special characteristics of the silt and clay fractions.

A distinction is made between silt and clay. What we call *clays* for classification purposes depends on the existence of clay minerals in the *fines fraction* (silt and clay sizes) of the soil, as well as size of the particles. These clay minerals have a different composition and behavior than silts and coarse-grained soils.

Clays display the characteristic of *plasticity*. For the most part, particles that are clay size are also clay minerals. The plasticity characteristics of the fines fraction of a soil is measured in the laboratory by the *Atterberg limit tests*. The Atterberg limits used most in classification are the liquid limit and plasticity index. In the field, where laboratory tests are not available, clays can be informally distinguished from silts by using the following simple "visual identification" tests.

Dry strength test: A small brick of soil is molded and allowed to air dry. The brick is broken and a small (1/8 in or 3 mm) fragment is taken between thumb and finger. A silt fragment will break easily, whereas clay will not.

Dilatancy test: A small sample is mixed with water to form a thick slurry. When the sample is squeezed, water will flow back into a silty sample quickly. The return rate will be much lower for clay.

Plasticity test: A moist soil sample is rolled into a thin (1/8 in or 3 mm) thread. As the thread dries, silt will be weak and friable, but clay will be tough.

Table 35.4 *AASHTO Soil Classification System*

	granular materials (35% or less passing no. 200 sieve)							silt-clay materials (more than 35% passing no. 200 sieve)				
	A-1		A-3	A-2				A-4	A-5	A-6	A-7	A-8
	A-1-a	A-1-b		A-2-4	A-2-5	A-2-6	A-2-7				A-7-5 or A-7-6	
sieve analysis: % passing												
no. 10	50 max											
no. 40	30 max	50 max	51 min									
no. 200	15 max	25 max	10 max	35 max	35 max	35 max	35 max	36 min	36 min	36 min	36 min	
characteristics of fraction passing no. 40:												
LL: liquid limit				40 max	41 min	40 max	41 min	40 max	41 min	40 max	41 min	
PI: plasticity index	6 max		NP	10 max	10 max	11 min	11 min	10 max	10 max	11 min	11 min	
usual types of significant constituents	stone fragments gravel and sand		fine sand	silty or clayey gravel and sand				silty soils		clayey soils		peat, highly organic soils
general subgrade rating	excellent to good			fair to poor								unsatisfactory

Classification procedure: Using the test data, proceed from left to right in the chart. The correct group will be found by process of elimination. The first group from the left consistent with the test data is the correct classification. The A-7 group is subdivided into A-7-5 or A-7-6, depending on the plastic limit. For plastic limit PL = LL − PI less than 30, the classification is A-7-6. For plastic limit PL = LL − PI greater than or equal to 30, it is A-7-5. NP means non-plastic.

Dispersion test: A sample of soil is dispersed in water. The time for the particles to settle is measured. Sand settles in 30 to 60 sec. Silt settles in 15 to 60 min, and clay remains in suspension for a long time.

Organic matter can also be present in soil. Generally, the greater the organic content, the darker the soil color. Organic matter can have a significant effect (usually negative) on the mechanical properties of the soil.

3. AASHTO SOIL CLASSIFICATION

The American Association of State Highway Transportation Officials' (AASHTO) classification system is based on the sieve analysis, liquid limit, and plasticity index. The best soils suitable for use as roadway subgrades are classified as A-1. Highly organic soils not suitable for roadway subgrades are classified as A-8. Soils can also be classified into subgroups. The AASHTO classification methodology is given in Table 35.4.

The *group index*, given by Eq. 35.3, may be added to the group classification. The group index is a means of comparing soils within a group, not between groups. A soil with a group index of zero is a good subgrade material within its particular group. Group indexes of 20 or higher represent poor subgrade materials. The group index, I_g, is reported to the nearest whole number but is reported as zero if it is calculated to be negative. (The liquid limit, LL, and plasticity index, PI, are discussed in Sec. 14.)

$$I_g = (F_{200} - 35)\big(0.2 + 0.005(\mathrm{LL} - 40)\big) + 0.01(F_{200} - 15)(\mathrm{PI} - 10) \qquad 35.3$$

F_{200} in Eq. 35.3 is the percentage of soil that passes through a no. 200 sieve. The quantities LL − 40 and PI − 10 may be negative. For the A-2-6 and A-2-7 subgroups, only the second term in Eq. 35.3 is used in calculating the group index.

4. UNIFIED SOIL CLASSIFICATION

The *Unified Soil Classification System* (USCS) is described in Table 35.5. Like the AASHTO system, it is based on the grain size distribution, liquid limit, and plasticity index of the soil.

Soils are classified into USCS groups that are designated by a group symbol and a corresponding group name. The symbols each contain two letters: The first represents the most significant particle size fraction, and the second is a descriptive modifier. Some categories require dual symbols.

Coarse-grained soils are divided into two categories: gravel soils (symbol G) and sand soils (symbol S). Sands and gravels are further subdivided into four subcategories as follows.

symbol W:	well-graded, fairly clean
symbol C:	significant amounts of clay
symbol P:	poorly graded, fairly clean
symbol M:	significant amounts of silt

Fine-grained soils are divided into three categories: inorganic silts (symbol M), inorganic clays (symbol C), and organic silts and clays (symbol O).[2] These three are subdivided into two subcategories as follows.

symbol L:	low compressibilities (LL less than 50)
symbol H:	high compressibilities (LL 50 or greater)

Example 35.1

Determine the classification of an inorganic soil with the characteristics listed using (a) the AASHTO and (b) the USCS classification systems.

soil size (mm)	fraction retained on sieve	
< 0.002	0.19	LL = 53
0.002–0.005	0.12	PL = 22
0.005–0.05	0.36	
0.05–0.075	0.04	$F_{200} = 0.04 + 0.36 + 0.12 + 0.19 = 0.71$
0.075–2.0	0.29	
> 2.0	0	

Solution

(a) From Table 35.2, the no. 200 sieve has an opening of 0.075 mm. F_{200} is 0.71, so from Table 35.4, the soil is first classified as a silt-clay material (more than 35% passing a no. 200 sieve). For a liquid limit of 53 and a plastic limit of 22, the classification is A-7-5 or A-7-6. Since the plastic limit is 22 (less than 30), the classification is A-7-6. The group index is

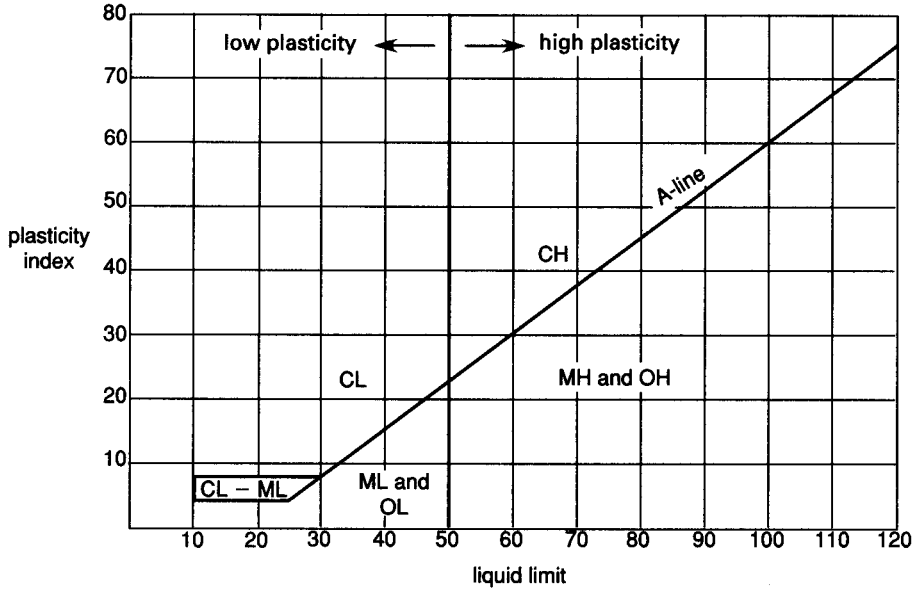
$$\begin{aligned} I_g &= (71 - 35)\big(0.2 + 0.005(53 - 40)\big) \\ &\quad + 0.01(71 - 15)(31 - 10) \\ &= 21.3 \end{aligned}$$

Round 21.3 to the nearest whole number. The soil classification is A-7-6 (21).

(b) From Table 35.5, the soil is first classified as a fine-grained soil (more than 50% passing the no. 200 sieve). The liquid limit is greater than 50 (LL = 53). The plasticity index is given by Eq. 35.23.

$$\mathrm{PI} = \mathrm{LL} - \mathrm{PL} = 53 - 22 = 31$$

Since the soil plots above the A-line, it is classified as CH: a highly plastic clay.



[2]The symbol M comes from the Swedish *mjala* (meaning silt) and *mo* (meaning very fine sand).

Geotechnical

Table 35.5 *Unified Soil Classification System*

major division		group symbol	laboratory classification criteria: finer than 200 sieve (%)	laboratory classification criteria: supplementary requirements	soil description
coarse-grained (over 50% by weight coarser than no. 200 sieve)	gravelly soils (over half of coarse fraction larger than no. 4)	GW	0–5*	D_{60}/D_{10} greater than 4 $D_{30}^2/(D_{60} \times D_{10})$ between 1 and 3	well-graded gravels, sandy gravels
		GP	0–5*	not meeting above gradation for GW	gap-graded or uniform gravels, sandy gravels
		GM	12 or more*	PI less than 4 or below A-line	silty gravels, silty sandy gravels
		GC	12 or more*	PI over 7 and above A-line	clayey gravels, clayey sandy gravels
	sandy soils (over half of coarse fraction finer than no. 4)	SW	0–5*	D_{60}/D_{10} greater than 4 $D_{30}^2/(D_{60} \times D_{10})$ between 1 and 3	well-graded, gravelly sands
		SP	0–5*	not meeting above gradation requirements	gap-graded or uniform sands, gravelly sands
		SM	12 or more*	PI less than 4 or below A-line	clayey sands, clayey gravelly sands
		SC	12 or more*	PI over 7 and above A-line	
fine-grained (over 50% by weight finer than no. 200 sieve)	low compressibility (liquid limit less than 50)	ML	plasticity chart		silts, very fine sands, silty or clayey fine sands, micaceous silts
		CL	plasticity chart		low plasticity clays, sandy or silty clays
		OL	plasticity chart, organic odor or color		organic silts and clays of high plasticity
	high compressibility (liquid limit more than 50)	MH	plasticity chart		micaceous silts, diatomaceous silts, volcanic ash
		CH	plasticity chart		highly plastic clays and sandy clays
		OH	plasticity chart, organic odor or color		organic silts and clays of high plasticity
soils with fibrous organic matter		Pt	fibrous organic matter; will char, burn, or glow		peat, sandy peats, and clayey peat

*For soils having 5 to 12% passing the no. 200 sieve, use a dual symbol such as GW-GC.

Plasticity chart for the classification of fine-grained soils. Tests made on fraction finer than no. 40 sieve, 0.425 mm.

5. MASS-VOLUME RELATIONSHIPS

Soil consists of solid soil particles separated by voids. The voids can be filled with either air or water. Thus, soil is a three-phase material (solids, water, and air). The percentages by volume, mass, and weight of these three constituents are used to calculate the aggregate properties.

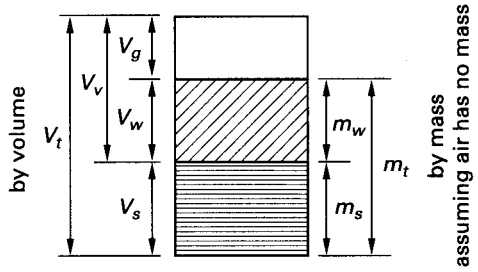


Figure 35.4 *Soil Phases*

The *porosity*, n, is the ratio of the volume of voids to the total volume.

$$n = \frac{V_v}{V_t} = \frac{V_g + V_w}{V_g + V_w + V_s} \qquad 35.4$$

The *void ratio*, e, is the ratio of the volume of voids to the volume of solids.

$$e = \frac{V_v}{V_s} = \frac{V_g + V_w}{V_s} \qquad 35.5$$

The *moisture content* (*water content*), w, is the ratio of the mass of water to the mass of solids, usually expressed in percent[3].

$$w = \frac{m_w}{m_s} \times 100\% \qquad 35.6$$

The *degree of saturation*, S, is the percentage of the volume of water to the total volume of voids.[3] This indicates how much of the void space is filled with water. If all the voids are filled with water, then the volume of air is zero and the sample's degree of saturation is 100%. The sample is said to be fully saturated.

$$\begin{aligned} S &= \frac{V_w}{V_v} \times 100\% \\ &= \frac{V_w}{V_g + V_w} \times 100\% \end{aligned} \qquad 35.7$$

The *density* (also called the *total density*), ρ, is the ratio of the total mass to the total volume. The total density may be referred to as the *moist density* (*wet density*) above the water table and as the *saturated density* below the water table.

$$\rho = \frac{m_t}{V_t} = \frac{m_w + m_s}{V_g + V_w + V_s} \qquad 35.8$$

[3]Both water content and saturation are reported as percentages; however, in working problems it is easiest to use the decimal form.

In the United States, weight is commonly used in soil calculations instead of mass. The corresponding density is called *unit weight*, γ. Weight is calculated $W = mg/g_c$, where g_c is the gravitational constant, 32.2 ft-lbm/lbf-sec^2. In Eqs. 35.8 and 35.10 through 35.14, γ can be substituted for ρ whenever convenient.[4]

$$\gamma = \rho g \qquad \text{[SI]} \qquad 35.9(a)$$

$$\gamma = \frac{\rho g}{g_c} \qquad \text{[U.S.]} \qquad 35.9(b)$$

The *dry density*, ρ_d, is the ratio of the solid mass to the total volume.

$$\rho_d = \frac{m_s}{V_t} = \frac{m_s}{V_g + V_w + V_s} \qquad 35.10$$

If the water content is known, the dry density of a moist sample can be found from Eq. 35.11.

$$\rho_d = \frac{m_t}{(1+w)V_t} = \frac{\rho}{1+w} \qquad 35.11$$

The *buoyant density* (*submerged density*), ρ_b, is the difference between the total density and the density of water.

$$\rho_b = \rho - \rho_w \qquad 35.12$$

The density of the solid constituents, ρ_s, is the ratio of the mass of the solids to the volume of the solids. This would also be the density of soil if there were no voids. For that reason, ρ_s is also known as the *solid density* and *zero-voids density*.

$$\rho_s = \frac{m_s}{V_s} \qquad 35.13$$

The *percent pore space*, PPS, is the ratio of the volume of the voids to the total volume, in percent.

$$\begin{aligned} \text{PPS} &= \frac{V_v}{V_t} \times 100\% \\ &= \left(1 - \frac{V_s}{V_t}\right) \times 100\% \\ &= \left(1 - \frac{\rho_d}{\rho_s}\right) \times 100\% \end{aligned} \qquad 35.14$$

The *specific gravity*, SG, of the solid constituents is given by Eq. 35.15. For practical purposes, the density of water, ρ_w, is 62.4 lbm/ft^3 (1000 kg/m^3). The specific gravity of most soils is within the range of 2.65 to 2.70, with clays as high as 2.9 and organic soils as low as 2.5.

$$\text{SG} = \frac{\rho_s}{\rho_w} \qquad 35.15$$

The *relative density*, D_r (also denoted as the *density index*, I_d), is the density of a granular soil relative to

[4]There is no concept of weight in SI units. The choice to work in weight or mass in U.S. units is somewhat arbitrary, because as long as the local gravitational field is essentially standard, the mass in lbm is numerically equal to the weight in lbf.

Geotechnical

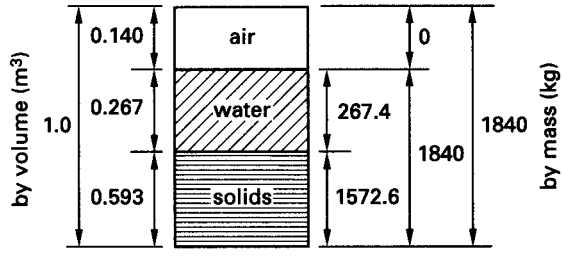
the minimum and maximum densities achieved for that soil in a laboratory test. This index is not applicable to clays, because clays do not densify in this particular laboratory test. The relative density is equal to 1 for a very dense soil and 0 for a very loose soil.

$$D_r = \frac{e_{\max} - e}{e_{\max} - e_{\min}} \qquad 35.16$$

Typical values of some of these soil parameters are given in Table 35.6. Useful relationships for computing the above soil indexes are summarized in Table 35.7.

Table 35.6 *Typical Soil Characteristics*

description	n	e	w_{sat}	ρ_d $\frac{\text{lbm}}{\text{ft}^3}$ $\left(\frac{\text{kg}}{\text{m}^3}\right)$	ρ_{sat} $\frac{\text{lbm}}{\text{ft}^3}$ $\left(\frac{\text{kg}}{\text{m}^3}\right)$
sand, loose and uniform	0.46	0.85	0.32	90 (1440)	118 (1890)
sand, dense and uniform	0.34	0.51	0.19	109 (1750)	130 (2080)
sand, loose and mixed	0.40	0.67	0.25	99 (1590)	124 (1990)
sand, dense and mixed	0.30	0.43	0.16	116 (1860)	135 (2160)
glacial clay, soft	0.55	1.20	0.45	76 (1200)	110 (1760)
glacial clay, stiff	0.37	0.60	0.22	106 (1700)	125 (2000)



(Multiply lbm/ft^3 by 16.02 to obtain kg/m^3.)

Example 35.2

What is the degree of saturation for a sand sample with SG = 2.65, ρ = 115 lbm/ft^3 (1840 kg/m^3), and w = 17%?

SI Solution

Draw the various mass and volume phases on a phase diagram. Since an actual mass or volume of soil is not specified, arbitrarily assume any convenient volume, usually 1.0 m^3.

From Eq. 35.6,

$$m_w = wm_s = 0.17m_s$$

But, $m_t = m_w + m_s = 1840$ kg. (The mass of any air voids is negligible.)

$$0.17m_s + m_s = 1840 \text{ kg}$$

$$m_s = 1572.6 \text{ kg}$$

$$m_w = 267.4 \text{ kg}$$

The solids volume is given by Eq. 35.13.

$$V_s = \frac{m_s}{\rho_s}$$

From Eq. 35.15, $\rho_s = (\text{SG})\rho_w$.

$$V_s = \frac{m_s}{(\text{SG})\rho_w} = \frac{1572.6 \text{ kg}}{(2.65)(1000 \text{ kg/m}^3)} = 0.593 \text{ m}^3$$

Similarly, the water volume is

$$V_w = \frac{m_w}{\rho_w} = \frac{267.4 \text{ kg}}{1000 \frac{\text{kg}}{\text{m}^3}} = 0.267 \text{ m}^3$$

The air volume is

$$V_g = V_t - V_s - V_w = 1 \text{ m}^3 - 0.593 \text{ m}^3 - 0.267 \text{ m}^3 = 0.140 \text{ m}^3$$

The degree of saturation is given by Eq. 35.7.

$$S = \frac{V_w}{V_g + V_w} \times 100\% = \frac{0.267 \text{ m}^3}{0.140 \text{ m}^3 + 0.267 \text{ m}^3} \times 100\% = 66\%$$

Customary U.S. Solution

Draw the various mass and volume phases on a phase diagram. Since an actual mass or volume of soil is not specified, arbitrarily assume any convenient volume, usually 1.0 ft^3.

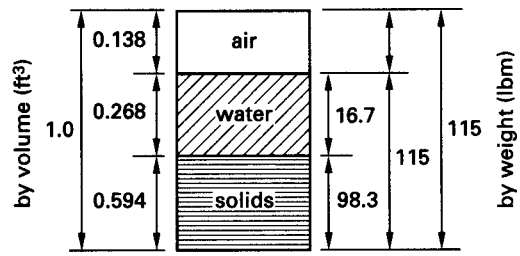


Table 35.7 *Soil Indexing Formulas*

SG	specific gravity of solids		$\frac{m_s}{V_s \rho_w}$	$\frac{Se}{w}$		

ρ_w is the density of water. Where noted with an asterisk (*), use the actual density of water. In other cases, use 62.4 lbm/ft^3 or 1000 kg/m^3.

From Eq. 35.6,

$$m_w = wm_s = 0.17m_s$$

However, $m_t = m_w + m_s = 115$ lbm. (The mass of any air voids is negligible.)

$$\begin{aligned} 0.17m_s + m_s &= 115 \text{ lbm} \\ m_s &= 98.3 \text{ lbm} \\ m_w &= 16.7 \text{ lbm} \end{aligned}$$

The solids volume is given by Eq. 35.13.

$$\begin{aligned} V_s &= \frac{m_s}{\rho_s} = \frac{m_s}{(\text{SG})\rho_w} \\ &= \frac{98.3 \text{ lbm}}{(2.65)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)} \\ &= 0.594 \text{ ft}^3 \end{aligned}$$

Similarly, the water volume is

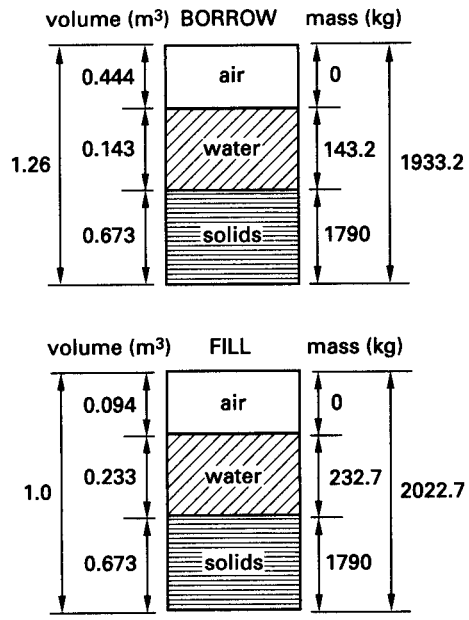
$$\begin{aligned} V_w &= \frac{m_w}{\rho_w} \\ &= \frac{16.7 \text{ lbm}}{62.4 \frac{\text{lbm}}{\text{ft}^3}} \\ &= 0.268 \text{ ft}^3 \end{aligned}$$

The air volume is

$$\begin{aligned} V_g &= V_t - V_s - V_w \\ &= 1 \text{ ft}^3 - 0.594 \text{ ft}^3 - 0.268 \text{ ft}^3 \\ &= 0.135 \text{ ft}^3 \end{aligned}$$

The degree of saturation is given by Eq. 35.7.

$$\begin{aligned} S &= \frac{V_w}{V_g + V_w} \times 100\% \\ &= \frac{0.268 \text{ ft}^3}{0.135 \text{ ft}^3 + 0.268 \text{ ft}^3} \times 100\% \\ &= 66\% \end{aligned}$$



Example 35.3

Borrow soil is used to fill a 100,000 yd^3 (75,000 m^3) depression. The borrow soil has the following characteristics: density = 96.0 lbm/ft^3 (1540 kg/m^3), water content = 8%, and specific gravity of the solids = 2.66. The final in-place dry density should be 112.0 lbm/ft^3 (1790 kg/m^3), and the final water content should be 13%.

(a) How many cubic yards (cubic meters) of borrow soil are needed? (b) Assuming no evaporation loss, what water mass is needed to achieve 13% moisture? (c) What will be the density of the in-place fill after a long rain?

SI Solution

Draw the phase diagrams for both the borrow and compacted fill soils. Use subscript B for borrow soil and F for fill soil, and work with 1 m^3 of fill material.

step 1: The air has no mass. The soil content (mass) is the same at both locations. (That is, getting 1790 kg of soil solids in the fill requires taking 1790 kg of borrow soil solids.) Per cubic meter of fill, the mass of borrow soil solids is

$$m_{s,B} = m_{s,F} = 1790 \text{ kg}$$

step 2: The mass of the water in 1 m^3 of fill is found from Eq. 35.6.

$$m_{w,F} = wm_{s,F} = (0.13)(1790 \text{ kg}) = 232.7 \text{ kg}$$

step 3: The total mass and density of the fill are

$$\begin{aligned} m_{t,F} &= m_{s,F} + m_{w,F} \\ &= 1790 \text{ kg} + 232.7 \text{ kg} = 2022.7 \text{ kg} \\ \rho_F &= \frac{m_{t,F}}{V_t} = \frac{2022.7 \text{ kg}}{1 \text{ m}^3} \\ &= 2022.7 \text{ kg/m}^3 \text{ fill} \end{aligned}$$

step 4: Since $\rho_s = m_s/V_s$, the volume of the solids in the fill is

$$\begin{aligned} V_{s,F} &= \frac{m_{s,F}}{\rho_{s,F}} \\ &= \frac{1790 \text{ kg}}{(2.66)\left(1000 \frac{\text{kg}}{\text{m}^3}\right)} \\ &= 0.673 \text{ m}^3 \end{aligned}$$

step 5: Similarly, the volume of the water in the fill is

$$\begin{aligned} V_{w,F} &= \frac{m_{w,F}}{\rho_{w,F}} \\ &= \frac{232.7 \text{ kg}}{1000 \frac{\text{kg}}{\text{m}^3}} \\ &= 0.233 \text{ m}^3 \end{aligned}$$

step 6: The air volume in the fill is

$$\begin{aligned} V_g &= V_t - V_s - V_w \\ &= 1 \text{ m}^3 - 0.673 \text{ m}^3 - 0.233 \text{ m}^3 \\ &= 0.094 \text{ m}^3 \end{aligned}$$

step 7: The mass of the water per cubic meter of fill in the borrow soil is given by Eq. 35.6.

$$\begin{aligned} m_{w,B} &= wm_{s,B} \\ &= (0.08)(1790 \text{ kg}) = 143.2 \text{ kg} \end{aligned}$$

step 8: The total mass of the borrow soil per cubic meter of fill is

$$\begin{aligned} m_{t,B} &= m_{s,B} + m_{w,B} \\ &= 1790 \text{ kg} + 143.2 \text{ kg} = 1933.2 \text{ kg} \end{aligned}$$

step 9: The total volume of the borrow soil per cubic meter of fill is

$$\begin{aligned} V_{t,B} &= \frac{m_{t,B}}{\rho_B} \\ &= \frac{1933.2 \text{ kg}}{1540 \frac{\text{kg}}{\text{m}^3}} \\ &= 1.26 \text{ m}^3 \end{aligned}$$

step 10: The mass of solids in 1 m^3 of fill is the same as the mass of solids in 1.26 m^3 of borrow soil. Since the mass is the same, the volume of solids is also the same, even though the total soil density is different. The volume of solids was calculated in step 4.

$$V_{s,B} = V_{s,F} = 0.673 \text{ m}^3$$

step 11: The volume of water in the borrow soil per cubic meter of fill is

$$\begin{aligned} V_{w,B} &= \frac{m_{w,B}}{\rho_w} \\ &= \frac{143.2 \text{ kg}}{1000 \frac{\text{kg}}{\text{m}^3}} \\ &= 0.143 \text{ m}^3 \end{aligned}$$

Geotechnical

step 12: The air volume in the borrow soil per cubic foot of fill is

$$\begin{aligned} V_{g,B} &= V_{t,B} - V_{s,B} - V_{w,B} \\ &= 1.26\ \text{m}^3 - 0.143\ \text{m}^3 - 0.673\ \text{m}^3 \\ &= 0.444\ \text{m}^3 \end{aligned}$$

step 13a: Since 1.26 m^3 of borrow soil is required for every 1 m^3 of fill, the volume of borrow soil required to fill the depression is

$$\begin{aligned} V_{\text{required},B} &= \left(\frac{1.26\ \text{m}^3}{1\ \text{m}^3}\right)(75\,000\ \text{m}^3) \\ &= 94\,500\ \text{m}^3 \end{aligned}$$

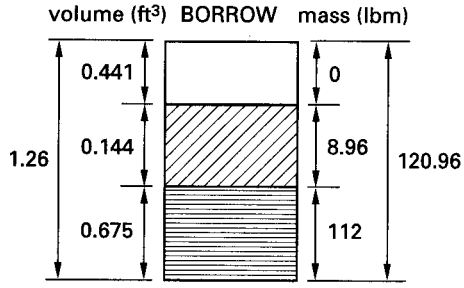
step 13b: The amount of water needed to achieve 13% moisture is the difference in mass of water between the fill and borrow soil. The actual moisture in the compacted borrow soil is

$$\begin{aligned} m_{B,\text{total}} &= V_{B,\text{total}}\left(\frac{m_{w,B}}{V_{t,B}}\right) \\ &= \frac{(94\,500\ \text{m}^3)(143.2\ \text{kg})}{1.26\ \text{m}^3} \\ &= 1.074 \times 10^7\ \text{kg} \end{aligned}$$

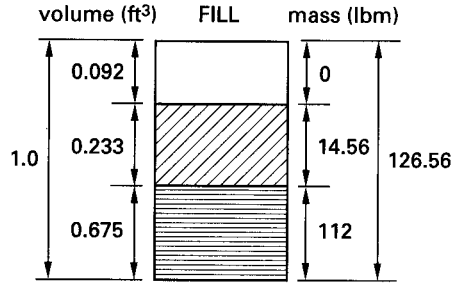
The required moisture in the fill soil is

$$\begin{aligned} m_{F,\text{total}} &= V_{F,\text{total}}\left(\frac{m_{w,F}}{V_{t,F}}\right) \\ &= \frac{(75\,000\ \text{m}^3)(232.7\ \text{kg})}{1\ \text{m}^3} \\ &= 1.745 \times 10^7\ \text{kg} \end{aligned}$$

The required additional moisture is



$$\begin{aligned} m_{w,\text{required}} &= m_{F,\text{total}} - m_{B,\text{total}} \\ &= 1.745 \times 10^7\ \text{kg} - 1.074 \times 10^7\ \text{kg} \\ &= 6.71 \times 10^6\ \text{kg} \end{aligned}$$



step 13c: After a rain, all the void spaces will be filled with water and the density will be the saturated density.

$$\begin{aligned} m_w &= (V_w + V_g)\rho_w \\ &= (0.233\ \text{m}^3 + 0.094\ \text{m}^3)\left(1000\ \frac{\text{kg}}{\text{m}^3}\right) \\ &= 327.0\ \text{kg} \\ \rho &= \frac{m_t}{V_t} = \frac{m_s + m_w}{V_t} \\ &= \frac{1790\ \text{kg} + 327.0\ \text{kg}}{1\ \text{m}^3} \\ &= 2117\ \text{kg/m}^3 \end{aligned}$$

Customary U.S. Solution

Draw the phase diagrams for both the borrow and compacted fill soils. Use subscript B for borrow soil and F for fill soil, and work with 1 ft^3 of fill material.

step 1: The air has no mass. The soil content (mass) is the same at both locations. (That is, getting 112 lbm of soil solids in the fill requires taking 112 lbm of borrow soil solids.) Per cubic foot of fill, the mass of borrow soil solids is

$$m_{s,B} = m_{s,F} = 112\ \text{lbm}$$

step 2: The mass of the water in 1 ft^3 of fill is given by Eq. 35.6.

$$m_{w,F} = wm_{s,F} = (0.13)(112\ \text{lbm}) = 14.56\ \text{lbm}$$

step 3: The total mass and density of the fill are

$$\begin{aligned} m_{t,F} &= m_{s,F} + m_{w,F} \\ &= 112\ \text{lbm} + 14.56\ \text{lbm} = 126.56\ \text{lbm} \\ \rho_F &= \frac{126.56\ \text{lbm}}{1\ \text{ft}^3} \\ &= 126.56\ \text{lbm/ft}^3\ \text{fill} \end{aligned}$$

step 4: Since $\rho_s = m_s/V_s$, the volume of the solids in the fill is

$$\begin{aligned} V_{s,F} &= \frac{m_{s,F}}{\rho_{s,F}} \\ &= \frac{112\ \text{lbm}}{(2.66)\left(62.4\ \frac{\text{lbm}}{\text{ft}^3}\right)} \\ &= 0.675\ \text{ft}^3 \end{aligned}$$

step 5: Similarly, the volume of the water in the fill is

$$V_{w,F} = \frac{m_{w,F}}{\rho_{w,F}} = \frac{14.56 \text{ lbm}}{62.4 \frac{\text{lbm}}{\text{ft}^3}} = 0.233 \text{ ft}^3$$

step 6: The air volume in the fill is

$$V_g = V_t - V_s - V_w = 1 \text{ ft}^3 - 0.233 \text{ ft}^3 - 0.675 \text{ ft}^3 = 0.092 \text{ ft}^3$$

step 7: The mass of the water per cubic foot of fill in the borrow soil is given by Eq. 35.6.

$$m_{w,B} = wm_{s,B} = (0.08)(112 \text{ lbm}) = 8.96 \text{ lbm}$$

step 8: The total mass of the borrow soil per cubic foot of fill is

$$m_{t,B} = m_{s,B} + m_{w,B} = 112 \text{ lbm} + 8.96 \text{ lbm} = 120.96 \text{ lbm}$$

step 9: The total volume of the borrow soil per cubic foot of fill is

$$V_{t,B} = \frac{m_{t,B}}{\rho_B} = \frac{120.96 \text{ lbm}}{96 \frac{\text{lbm}}{\text{ft}^3}} = 1.26 \text{ ft}^3$$

step 10: The mass of solids in 1 ft^3 of fill is the same as the mass of solids in 1.26 ft^3 of borrow soil. Since the mass is the same, the volume of solids is also the same, even though the total soil density is different. The volume of solids was calculated in step 4.

$$V_{s,B} = V_{s,F} = 0.675 \text{ ft}^3$$

step 11: The volume of water in the borrow soil per cubic foot of fill is

$$V_{w,B} = \frac{m_{w,B}}{\rho_w} = \frac{8.96 \text{ lbm}}{62.4 \frac{\text{lbm}}{\text{ft}^3}} = 0.144 \text{ ft}^3$$

step 12: The air volume in the borrow soil per cubic foot of fill is

$$V_{g,B} = V_{t,B} - V_{s,B} - V_{w,B} = 1.26 \text{ ft}^3 - 0.144 \text{ ft}^3 - 0.675 \text{ ft}^3 = 0.441 \text{ ft}^3$$

step 13a: Since 1.26 ft^3 of borrow soil are required for every 1 ft^3 of fill, the volume of borrow soil required to fill the depression is

$$V_{\text{required},B} = \left(\frac{1.26 \text{ ft}^3}{1 \text{ ft}^3}\right)(100{,}000 \text{ yd}^3) = 126{,}000 \text{ yd}^3$$

step 13b: The amount of water needed to achieve 13% moisture is the difference in mass of water between the fill and borrow soil. The actual moisture in the compacted borrow soil is

$$m_{B,\text{total}} = V_{B,\text{total}}\left(\frac{m_{w,B}}{V_{t,B}}\right) = \frac{(126{,}000 \text{ yd}^3)\left(27 \frac{\text{ft}^3}{\text{yd}^3}\right)(8.96 \text{ lbm})}{1.26 \text{ ft}^3} = 2.42 \times 10^7 \text{ lbm}$$

The required moisture in the fill soil is

$$m_{F,\text{total}} = V_{F,\text{total}}\left(\frac{m_{w,F}}{V_{t,F}}\right) = (100{,}000 \text{ yd}^3)\left(27 \frac{\text{ft}^3}{\text{yd}^3}\right)\left(14.56 \frac{\text{lbm}}{\text{ft}^3}\right) = 3.93 \times 10^7 \text{ lbm}$$

The required additional moisture is

$$m_{w,\text{required}} = m_{F,\text{total}} - m_{B,\text{total}} = 3.93 \times 10^7 \text{ lbm} - 2.42 \times 10^7 \text{ lbm} = 1.51 \times 10^7 \text{ lbm}$$

step 13c: After a rain, all the void spaces will be filled with water and the density will be the saturated density.

$$m_w = (V_w + V_g)\rho_w = (0.233 \text{ ft}^3 + 0.092 \text{ ft}^3)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right) = 20.28 \text{ lbm}$$

$$\rho = \frac{m_t}{V_t} = \frac{m_s + m_w}{V_t} = \frac{112.0 \text{ lbm} + 20.28 \text{ lbm}}{1.0 \text{ ft}^3} = 132.3 \text{ lbm/ft}^3$$

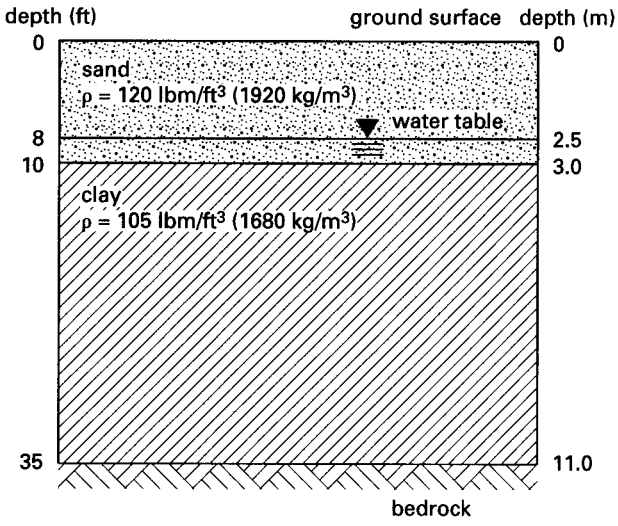
Geotechnical

6. SWELL

Swell occurs when clayey soils are used at lower loadings and/or higher moisture contents than existed prior to excavation. A small percentage may need to be added to calculated borrow-soil volumes to account for swell. Actual swell percentages are difficult to predict, but are typically less than 5%. Soils with large swell percentages are probably not suitable for foundation fill.

7. EFFECTIVE STRESS

Each of the three phases (solids, water, and air) in soil have different characteristics. Unlike other construction materials that essentially perform as homogeneous media, the three phases in soil interact with each other: Water and air can enter or leave the soil, and the soil grains can be pushed closer together. The water and air in the soil voids cannot support shear stress, so shear is supported entirely through grain-to-grain contact.



The *effective stress*, σ', is the portion of the total stress that is supported through grain contact. It is the difference between the *total stress*, σ, and the *pore water pressure*, u. (The pore water pressure is sometimes called the *neutral stress* because it is equal in all directions; that is, it has no shear stress component.) The effective stress is the average stress on a plane through the soil, not the actual contact stress between two soil particles (which can be much higher).

$$\sigma' = \sigma - u \qquad 35.17$$

The stresses in a soil element at depth z below the ground surface include those due to the weight above that element (called the *overburden stress*) and any buoyant forces that the water in the soil voids exerts. The stress in a soil column can be divided into total stress, effective stress, and pore pressure components. Above the water table, total and effective stresses are equal. Below the water table, the pore water exerts a buoyant force, and this hydrostatic stress is subtracted from the total stress to obtain the effective stress.

Example 35.4

Given the soil profile and properties illustrated, draw the total stress, effective stress, and pore pressure diagrams.

SI Solution

The total stress profile is a profile of the total weight of the soil column with depth. Assume that the moist density of the sand above the water table is equal to the saturated density below the water table. The total stress at a depth of 3 m is

$$\begin{aligned}\sigma_{3\text{ m}} &= \rho g z \\ &= \left(1920\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(3\text{ m}) \\ &= 56\,505\text{ Pa}\quad (56.5\text{ kPa})\end{aligned}$$

At a depth of 11 m, the total stress is

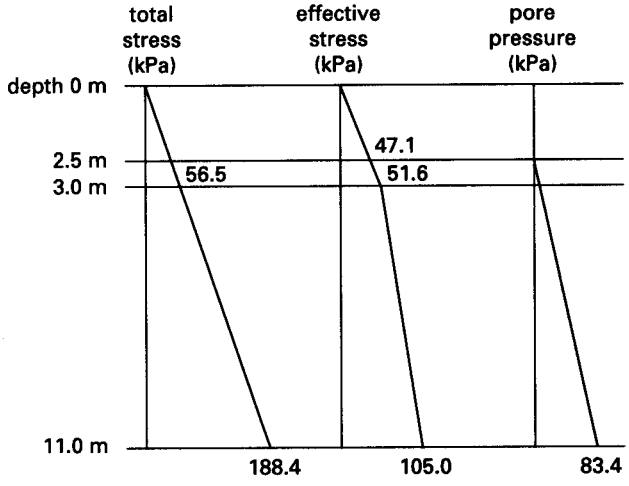
$$\begin{aligned}\sigma_{11\text{ m}} &= \sigma_{3\text{ m}} + \rho g z \\ &= 56\,505\text{ Pa} + \left(1680\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(11\text{ m} - 3\text{ m}) \\ &= 188\,351\text{ Pa}\quad (188.4\text{ kPa})\end{aligned}$$

The pore water pressure above the water table is zero. Below the water table, the pore water pressure is equal to the weight of the water column. At a depth of 11 m, the pore water pressure is

$$\begin{aligned}u_{11\text{ m}} &= \rho_w g z \\ &= \left(1000\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(8.5\text{ m}) \\ &= 83\,355\text{ Pa}\quad (83.4\text{ kPa})\end{aligned}$$

The effective stress profile is determined by subtracting the pore water pressure from the total stress, or by using buoyant weights below the water table. Above the water table, the total and effective stresses are equal.

At a depth of 2.5 m, the effective stress is



$$\begin{aligned}\sigma'_{2.5\text{ m}} &= \rho g z \\ &\left(1920\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(2.5\text{ m}) \\ &= 47\,088\text{ Pa}\quad (47.1\text{ kPa})\end{aligned}$$

At a depth of 3 m, the effective stress is

$$\begin{aligned}\sigma'_{3\text{ m}} &= \sigma_{2.5\text{ m}} + \rho g z \\ &= 47\,088\text{ Pa} + \left(1920\ \frac{\text{kg}}{\text{m}^3} - 1000\ \frac{\text{kg}}{\text{m}^3}\right) \\ &\quad \times (0.5\text{ m})\left(9.81\ \frac{\text{m}}{\text{s}^2}\right) \\ &= 51\,601\text{ Pa}\ \ (51.6\text{ kPa})\end{aligned}$$

At a depth of 11 m, the effective stress is

$$\begin{aligned}\sigma'_{11\text{ m}} &= 51\,601\text{ Pa} + \left(1680\ \frac{\text{kg}}{\text{m}^3}\right. \\ &\quad \left. - 1000\ \frac{\text{kg}}{\text{m}^3}\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)(8\text{ m}) \\ &= 104\,967\text{ Pa}\ \ (105.0\text{ kPa})\end{aligned}$$

Customary U.S. Solution

The total stress profile is a profile of the total weight of the soil column with depth. Assume that the moist density of the sand above the water table is equal to the saturated density below the water table. The total stress at a depth of 10 ft is

$$\begin{aligned}\sigma_{10\text{ ft}} &= \gamma z \\ &= \left(120\ \frac{\text{lbf}}{\text{ft}^3}\right)(10\text{ ft}) \\ &= 1200\text{ lbf/ft}^2\end{aligned}$$

At a depth of 35 ft, the total stress is

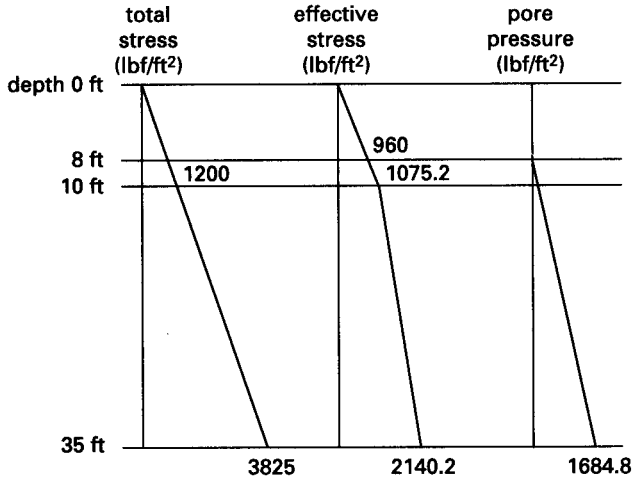
$$\begin{aligned}\sigma_{35\text{ ft}} &= \sigma_{10\text{ ft}} + \gamma z \\ &= 1200\ \frac{\text{lbf}}{\text{ft}^2} + \left(105\ \frac{\text{lbf}}{\text{ft}^3}\right)(25\text{ ft}) \\ &= 3825\text{ lbf/ft}^2\end{aligned}$$

The pore water pressure above the water table is zero. Below the water table, the pore water pressure is equal to the weight of the water column. At a depth of 35 ft, the pore water pressure is

$$\begin{aligned}u_{35\text{ ft}} &= \left(62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(35\text{ ft} - 8\text{ ft}) \\ &= 1684.8\text{ lbf/ft}^2\end{aligned}$$

The effective stress profile is determined by subtracting the pore water pressure from the total stress, or by using buoyant densities below the water table. Above the water table, the total and effective stresses are equal.

At a depth of 8 ft, the effective stress is



$$\begin{aligned}\sigma'_{8\text{ ft}} &= \gamma z \\ &= \left(120\ \frac{\text{lbf}}{\text{ft}^3}\right)(8\text{ ft}) = 960\text{ lbf/ft}^2\end{aligned}$$

At a depth of 10 ft, the effective stress is

$$\begin{aligned}\sigma'_{10\text{ ft}} &= 960\ \frac{\text{lbf}}{\text{ft}^2} + \left(120\ \frac{\text{lbf}}{\text{ft}^3} - 62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(2\text{ ft}) \\ &= 1075.2\text{ lbf/ft}^2\end{aligned}$$

At a depth of 35 ft, the effective stress is

$$\begin{aligned}\sigma'_{35\text{ ft}} &= 1075.2\ \frac{\text{lbf}}{\text{ft}^2} + \left(105\ \frac{\text{lbf}}{\text{ft}^3} - 62.4\ \frac{\text{lbf}}{\text{ft}^3}\right)(25\text{ ft}) \\ &= 2140.2\text{ lbf/ft}^2\end{aligned}$$

8. STANDARDIZED SOIL TESTING PROCEDURES

Soil testing procedures and equipment vary from laboratory to laboratory and depend on specific project needs. To compare results, consistent methodologies are necessary. For this reason, government and professional agencies have developed standards for commonly performed tests. Table 35.8 lists some of the soils tests that have been standardized by the American Society for Testing and Materials (ASTM). Most of the procedures referred to in this chapter have been chosen in accordance with ASTM standards.

Table 35.8 *ASTM Standard Soils Tests*

test	ASTM designation[1]	title (abbreviated)
AASHTO Soil Classification	D3282	Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes
USCS Soil Classification	D2487	Classification of Soils for Engineering Purposes
Standard Penetration Test	D1586	Penetration Test and Split-Barrel Sampling of Soils
Cone Penetrometer Test	D3441	Deep, Quasi-Static, Cone and Friction Cone Penetration Tests of Soil
Proctor/Modified Proctor Test	D698 D1557	Laboratory Compaction Characteristics - Using Standard Effort - Using Modified Effort
In-Place Density Test	D2922 D2167 D1556	Nuclear Methods (Shallow Depth) Rubber-Balloon Method Sand-Cone Method
Atterberg Limit Tests	D4318	Liquid Limit, Plastic Limit, and Plasticity Index of Soils
Permeability Tests	D2434	Permeability of Granular Soils (Constant Head)
Consolidation Tests	D2435	One-Dimensional Consolidation Properties of Soils
Direct Shear Tests	D3080	Direct Shear Test of Soils Under Consolidated Drained Conditions
Triaxial Stress Tests	D2850 D4767	UU Tests, Cohesive Soils CU Tests, Cohesive Soils
Unconfined Compressive Strength Test	D2166	Unconfined Compressive Strength of Cohesive Soil
CBR Test	D1883	CBR (California Bearing Ratio) of Laboratory Compacted Soils
Plate Bearing Value Test	D1195	Repetitive Static Plate Load Tests of Soils and Flexible Pavement Components
Hveem's Resistance Value Test	D2844	Resistance *R*-Value and Expansion Pressure of Compacted Soils

Adapted from the 1997 *Annual Book of ASTM Standards*

9. STANDARD PENETRATION TEST

A common soils test is the *standard penetration test* (SPT), which is performed in situ as part of the drilling and sampling operation. (The term "in situ" is synonymous with "in place.") The SPT measures resistance to the penetration of a standard split-spoon sampler that is driven by a 140 lbm (63.5 kg) hammer dropped from a height of 30 in (0.76 m). The number of blows required to drive the sampler a distance of 12 in (0.305 m) after an initial penetration of 6 in (0.15 m) is referred to as the *N-value* or *standard penetration resistance* in blows per foot.

The measured value of N is inconsistent from operator to operator because different drill rig systems deliver energy input that deviates from the theoretical value. Therefore, the N-value obtained in the field is converted to a standardized N-value, N'. In addition, because the N-value is sensitive to overburden pressure, corrections are applied to reference the value to a standard overburden stress, usually 2000 lbf/ft^2 (95.76 kPa).

The N-value has been correlated with many other mechanical properties, including shear modulus, unconfined compressive strength, angle of internal friction, and relative density. The correlations work best with cohesionless soils. Table 35.9 relates N to the relative density and friction angle.

Table 35.9 *Relationship between SPT (N), Relative Density (D_r), and Angle of Internal Friction (ϕ) (cohesionless soils)*

			angle of internal friction, ϕ	
type of soil	SPT, N	relative density, D_r	Peck, et al. (1974)	Meyerhof (1956)
very loose sand	< 4	< 0.02	< 29	< 30
loose sand	4–10	0.2–0.4	29–30	30–35
medium sand	10–30	0.4–0.6	30–36	35–40
dense sand	30–50	0.6–0.8	36–41	40–45
very dense sand	> 50	> 0.8	> 41	> 45

10. CONE PENETROMETER TEST

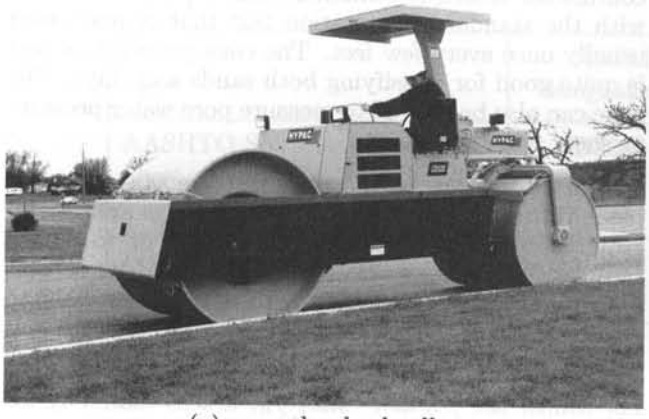
The *cone penetrometer test* (CPT) has gained popularity as an alternative or adjunct to the standard penetration test. The standard cone penetrometer is a cylinder with an area of 1.55 in^2 (10 cm^2), tipped with a cone that has a 60° point. The cone is pushed into the soil at a continuous rate of 2 to 4 ft/min (10 to 20 mm/s). Resistance is measured separately at the tip of the cone (tip resistance, q_c, in lbf/ft^2 or kPa) and along the sides (sleeve friction resistance, q_s, in lbf/ft^2 or kPa). A data acquisition system collects nearly continuous data with depth.

One advantage of the cone penetration test is that a continuous record is obtained with depth, in contrast with the standard penetration test that is performed usually once every few feet. The cone penetration test is quite good for classifying both sands and clays. The cone can also be altered to measure pore water pressure or shear wave velocity.

The disadvantages to the cone test are: (a) No sample is retrieved, so some additional borings are usually required to confirm classification results or to obtain samples for further tests; (b) the cone and its accompanying equipment require a high initial investment to acquire; and (c) the cone is easily damaged or stuck and cannot be used in very stiff or gravelly soils.

For sands, the *friction ratio*, f_R, is less than 1%; for clays, f_R is larger, up to 5% or more.

$$f_R = \frac{q_s}{q_c} \times 100\% \qquad 35.18$$



11. PROCTOR TEST

Soils are compacted to increase stability and strength, enhance resistance to erosion, decrease permeability, and decrease compressibility. This is usually accomplished by placing the soil in *lifts* (i.e., layers) of a few inches to a few feet thick, and then mechanically compacting the lifts. Compaction equipment can densify the soil by static loading, impact, vibration, and/or kneading actions. *Grid rollers* can be used to break up and compact rocky soil. Cohesive soils respond best to the kneading action that is provided by a *sheepsfoot roller*. *Rubber-tired* or *smooth-wheeled rollers* are especially useful for final finishes. Roller compactors with vibration capabilities are well-suited for cohesionless soils. These types of compaction equipment are shown in Fig. 35.5.

The specification given to the grading contractor sets forth the minimum acceptable density as well as a range of acceptable water content values. The minimum density is specified as a *relative compaction* (RC), the percentage of the maximum value determined in the laboratory, ρ_d^*.

$$\text{RC} = \frac{\rho_d}{\rho_d^*} \times 100\% \qquad 35.19$$

The basic laboratory test used to determine the maximum dry density of compacted soils is the *Proctor test*. In this procedure, a soil sample is compacted into a $^1/_{30}$ ft^3 (944 cm^3) mold in 3 layers by 25 hammer blows on each layer. The hammer has a mass of 5.5 lbm (2.5 kg) and is dropped 12 in (305 mm). The dry density of the sample can be found from Eq. 35.10. This procedure is repeated for various water contents, and a graph similar to Fig. 35.6 is obtained. ρ_d^* is known as the *maximum dry density*, or density at 100% compaction. w^* is known as the *optimum water content*.

(a) smooth-wheel roller

(b) rubber-tired roller

(c) sheepsfoot roller

(d) grid roller

Figure 35.5 *Compaction Equipment*

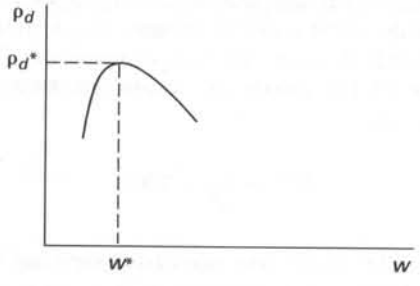

Figure 35.6 *Proctor Test Curve*

Soils close to the optimum water content require less compactive effort to achieve the required relative compaction. Usually a range of acceptable water contents, bracketing the optimum water content, is specified in addition to the relative compaction.

12. MODIFIED PROCTOR TEST

The *modified Proctor test* is similar to the Proctor test except that the soil is compacted in five layers with a 10 lbm (4.5 kg) hammer falling 18 in (457 mm). The result is a denser soil that is more representative of the compaction densities that can be achieved with modern equipment. The modified Proctor curve for a soil always lies above and to the left of the standard Proctor curve. Table 35.10 can be used by adding 10 to 20 lbm/ft^3 to the densities and subtracting 3 to 10% from the moisture contents.

For a given water content, perfect compaction will result in saturation, since all air will be removed. The dry densities corresponding to saturation at each water content can be plotted versus water content, and the result is known as a *zero air voids curve*. The zero air voids curve always lies above the Proctor test curve, since that test cannot expel all air.

Table 35.10 *Typical Values of Optimum Moisture Content and Suggested Relative Compactions (Based on Standard Proctor Test)*

class group symbol	description	range of maximum dry densities (lbm/ft^3)	range of optimum moisture content (%)	recommended percentage of Proctor maximum (%) class[a] 1	2	3
GW	well-graded, clean gravels, gravel-sand mixtures	125–135	11–8	97	94	90
GP	poorly graded clean gravels, gravel-sand mixtures	115–125	14–11	97	94	90
GM	silty gravels, poorly graded gravel-sand silt	120–135	12–8	98	94	90
GC	clayey gravels, poorly graded gravel-sand-clay	115–130	14–9	98	94	90
SW	well-graded clean sands, gravelly sands	110–130	16–9	97	95	91
SP	poorly graded clean sands, sand-gravel mix	100–120	21–12	98	95	91
SM	silty sands, poorly graded sand-silt mix	110–125	16–11	98	95	91
SM-SC	sand-silt-clay mix with slightly plastic fines	110–130	15–11	99	96	92
SC	clayey sands, poorly graded sand-clay mix	105–125	19–11	99	96	92
ML	inorganic silts and clayey silts	95–120	24–12	100	96	92
ML-CL	mixture of organic silt and clay	100–120	22–12	100	96	92
CL	inorganic clays of low-to-medium plasticity	95–120	24–12	100	96	92
OL	organic silts and silt-clays, low plasticity	80–100	33–21	–	96	93
MH	inorganic clayey silts, elastic silts	70–95	40–24	–	97	93
CH	inorganic clays of high plasticity	75–105	36–19	–	–	93
OH	organic and silty clays	65–100	45–21	–	97	93

(Multiply lbm/ft^3 by 16.02 to obtain kg/m^3.)
[a]Class 1 uses include the upper 9 ft (2.7 m) of fills supporting one- and two-story buildings, the upper 3 ft (0.9 m) of subgrade under pavements, and the upper 1 ft (0.3 m) of subgrade under floors. Class 2 uses include deeper parts of fills under buildings and pavements as well as earth dams. All other fills requiring some degree of strength or incompressibility are classified as class 3.

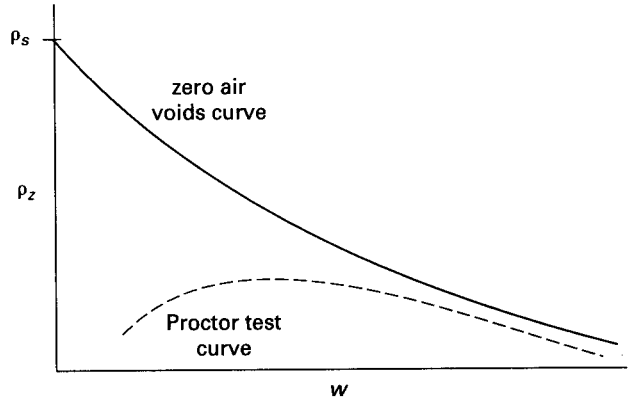

Figure 35.7 *Typical Zero Air Voids Curve*

The *zero air voids density* (i.e., *dry unit weight at zero air voids*) is the ratio of the mass of the solids to the total volume if the sample is fully compacted (i.e., there is no air in the voids).

$$\rho_z = \frac{m_s}{V_w + V_s} \qquad 35.20$$

The theoretical dry density of the zero air voids curve is calculated from Eq. 35.21.

$$\rho_z = \frac{\rho_w}{w + \frac{1}{\text{SG}}} \qquad 35.21$$

The maximum value of the zero air voids density occurs at $w = 0$. At that point, the maximum zero air voids density is equal to the density of the solid itself (as calculated from the solid specific gravity).

$$\rho_s = (\text{SG})\rho_w \qquad 35.22$$

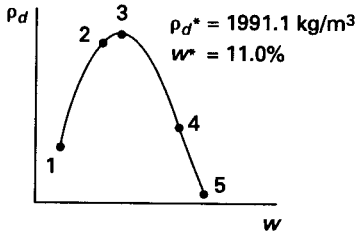
ρ_s and ρ_d^* are not the same, however, since air voids exist in the ρ_d^* case and ρ_d^* occurs at w^*.

Example 35.5

A Proctor test using a $\frac{1}{30}$ ft^3 (0.9443 L) mold is performed on a sample of soil.

test no.	sample net mass (lbm)	sample net mass (kg)	water content (%)
1	4.28	1.941	7.3
2	4.52	2.050	9.7
3	4.60	2.087	11.0
4	4.55	2.064	12.8
5	4.50	2.041	14.4

If 0.032 ft^3 (0.00091 m^3) of compacted soil tested at a construction site had a mass of 3.87 lbm (1.755 kg) wet and 3.74 lbm (1.696 kg) dry, what is the percentage of compaction?



SI Solution

From Eq. 35.11, the dry density of sample 1 is

$$\begin{aligned}\rho_d &= \frac{m_t}{(1+w)V_t} \\ &= \frac{1.941 \text{ kg}}{(1+0.073)(0.9443 \text{ L})\left(0.001 \dfrac{\text{m}^3}{\text{L}}\right)} \\ &= 1915.7 \text{ kg/m}^3\end{aligned}$$

The following table is constructed from the results of all five tests.

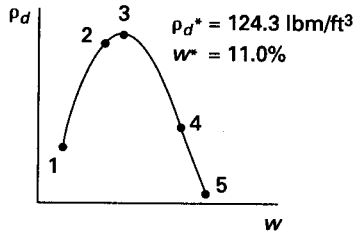
test no.	dry density (kg/m^3)
1	1915.7
2	1979.0
3	1991.1
4	1937.7
5	1889.4

Since the peak is near point 3, take the maximum dry density to be 1991.1 kg/m^3. The sample dry density is

$$\begin{aligned}\rho_d &= \frac{m_d}{V} = \frac{1.696 \text{ kg}}{0.00091 \text{ m}^3} \\ &= 1863.7 \text{ kg/m}^3\end{aligned}$$

The percentage of compaction is

$$\frac{1863.7 \dfrac{\text{kg}}{\text{m}^3}}{1991.1 \dfrac{\text{kg}}{\text{m}^3}} \times 100\% = 94\%$$



Customary U.S. Solution

From Eq. 35.11, the dry density of sample 1 is

$$\begin{aligned}\rho_d &= \frac{m_t}{(1+w)V_t} \\ &= \frac{4.28 \text{ lbm}}{(1+0.073)\left(\dfrac{1}{30} \text{ ft}^3\right)} \\ &= 119.7 \text{ lbm/ft}^3\end{aligned}$$

The following table is constructed from the results of all five tests.

test no.	dry density (lbm/ft^3)
1	119.7
2	123.6
3	124.3
4	121.0
5	118.0

Since the peak is near point 3, take the maximum dry density to be 124.3 lbm/ft^3. The sample dry density is

$$\begin{aligned}\rho_d &= \frac{m_d}{V} = \frac{3.74 \text{ lbm}}{0.032 \text{ ft}^3} \\ &= 116.9 \text{ lbm/ft}^3\end{aligned}$$

The percentage of compaction is

$$\frac{116.9 \dfrac{\text{lbm}}{\text{ft}^3}}{124.3 \dfrac{\text{lbm}}{\text{ft}^3}} \times 100\% = 94\%$$

13. IN-PLACE DENSITY TESTS

The *in-place density test*, also known as the *field density test*, determines the density of a compacted fill to see if it meets specifications. A 3 to 5 in (8 to 13 cm) deep hole with smooth sides is dug into the compacted soil. All soil taken from the hole is saved and weighed before the water content can change. The hole is filled with sand or a water-filled rubber balloon. The volume of the hole is calculated from the known mass and density of the sand or water. The required densities of the compacted soil are given by Eqs. 35.8 and 35.11.

Another way to determine the density of in-place soil is by using a *nuclear gauge* (*nuclear moisture/density gauge*). This device has a probe containing radioactive material that is inserted into a hole punched into the compacted soil. The rate of radiation penetration through the soil is detected and used to determine both the wet density and the water content of the soil. The dry density can be calculated with Eq. 35.11.

14. ATTERBERG LIMIT TESTS

A clay soil can behave like a solid, semi-solid, plastic solid, or liquid, depending on the water content. The water contents corresponding to the transitions between these states are known as the *Atterberg limits*.[5] Each of the Atterberg limits varies with the clay content, type of clay mineral, and ions (cations) contained in the clay. Tests that determine two of these Atterberg limits—the plastic limit and the liquid limit—are frequently used to classify clay soils.

The *plastic limit* (PL or w_p) is the water content corresponding to the transition between the semi-solid and plastic state. The *liquid limit* (LL or w_l) is the water content corresponding to the transition between the plastic and liquid state. A third limit that is occasionally used in soils engineering is the *shrinkage limit* (SL or w_s), which is the water content corresponding to the transition between a brittle solid and a semi-solid.[6]

The liquid limit test is performed with a special apparatus. A soil sample is placed in a shallow container and the sample is parted in half with a grooving tool. The container is dropped a distance of 0.4 in (10 mm) repeatedly until the sample has rejoined for a length of 1/2 in (13 mm). The liquid limit is defined as the water content at which the soil rejoins at exactly 25 blows. The test is repeated at different water contents, and the water content corresponding to the liquid limit is found by interpolation using a *flow curve* (a plot of water content versus logarithm of number of blows, N).

When a soil has a liquid limit of 100, the weight of water equals the weight of the dry soil (i.e., $w = 100\%$). A liquid limit of 50 means that the soil at the liquid limit is two-thirds soil and one-third water.

Sandy soils have low liquid limits—on the order of 20. In such soils, the test is of little significance in judging load-carrying capacities. Silts and clays can have significant liquid limits—most clays have liquid limits less than 100, but they can be as high as 1000.

The plastic limit test consists of rolling a soil sample into a 1/8 in (3 mm) thread. The sample will crumble at that diameter when it is at the plastic limit. The sample is remolded to remove moisture and rolled into a thread repeatedly until the plastic limit is reached. The water content is determined for three such samples, and the average value is the plastic limit.

Sands and most silts have no plastic limit at all. They are known as *nonplastic soils*. The test is of little significance in judging the relative load-carrying capacities of such soils. The plastic limit of clays and plastic silts can be from 0 to 100 or more, but it is usually less than 40.

[5]Although standard practice varies, it is suggested that Atterberg limits be reported as whole numbers rather than as percentages, to emphasize that they are an index of behavior, not a soil characteristic.

[6]The Atterberg limits are sometimes given the symbols w_L (liquid limit), w_P (plastic limit), and w_S (shrinkage limit).

The difference between the liquid and plastic limits is known as the *plasticity index*, PI. The plasticity index indicates the range in moisture content over which the soil is in a plastic condition. In this condition it can be deformed and still hold together without crumbling. A large plasticity index (i.e., greater than 20) shows that considerable water can be added before the soil becomes liquid. The plasticity index correlates with strength, deformation properties, and insensitivity.

$$\mathrm{PI} = \mathrm{LL} - \mathrm{PL} \qquad 35.23$$

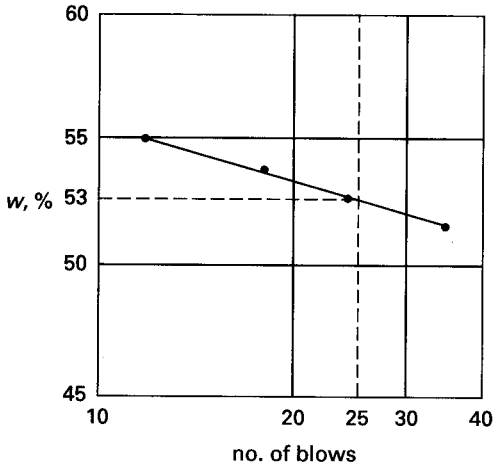
The difference between the plastic and shrinkage limits is known as the *shrinkage index*, SI. The shrinkage index indicates the range in moisture content over which the soil is in a semi-solid condition. The shrinkage limit is the water content at which further drying out of the soil does not decrease the volume of the soil. Below the shrinkage limit, air enters the voids and water content decreases are not accompanied by decreases in volume. The test consists of drying a brick of soil to remove all interstitial (removable) water, and then adding water until all the voids are filled.

$$\mathrm{SI} = \mathrm{PL} - \mathrm{SL} \qquad 35.24$$

The *consistency* of a clay means the water content relative to the Atterberg limits. This is represented by the *liquidity index*, LI.[7] A liquidity index between 0 and 1 indicates that the water content is between the plastic limit and the liquid limit; a liquidity index greater than one indicates that the water content is above the liquid limit.

$$\mathrm{LI} = \frac{w - \mathrm{PL}}{\mathrm{PI}} \qquad 35.25$$

Example 35.6



Atterberg limit tests were performed on a silty clay. The water contents obtained in the plastic limit test were 31.6%, 33.5%, and 30.9%. The following data were obtained in the liquid limit test. What are the (a) liquid limit, (b) plastic limit, and (c) plasticity index?

no. of blows	water content
12	54.8%
18	54.2%
23	52.9%
35	51.9%

Solution

(a) For the liquid limit, plot the logarithm of the number of blows versus the water content. The liquid limit corresponding to the water content at 25 blows is 53%.

[7]Alternative symbols are IL for liquidity index and IP for plasticity index.

(b) The plastic limit is the average of the three test results.

$$\text{PL} = \frac{31.6 + 33.5 + 30.9}{3} = 32$$

(c) The plasticity index is given by Eq. 35.23.

$$\text{PI} = \text{LL} - \text{PL} = 53 - 32 = 21$$

15. PERMEABILITY TESTS

Permeability of a soil is a measure of continuous voids. It is not enough for a soil to have large voids. The voids must also be connected for water to flow through them. A permeable material permits a significant flow of water. The flow of water through a permeable aquifer or soil is given by Eq. 35.26, known as *Darcy's law*.

$$Q = \text{v}A_{\text{gross}} \qquad 35.26$$

$$\text{v} = Ki \qquad 35.27$$
